Approximate controllability of abstract semilinear control systems. **Nagarajan Sukavanam** (IIT Bombay, India), Divya Divya (IIT Roorkee, India) IC/CT3634/030

In this paper we prove the approximate controllability (a.c) of semilinear control systems of the form

$$x_u'(t) = Ax_u(t) + Bu(t) + f(t, x_u(t)); 0 \leqslant t \leqslant T \quad (1a)$$

$$x_u(0) = 0 \quad (1b)$$

where the state $x_u(t)$ of the system takes values in a Hilbert space V and the control function $u(t)$ takes its values in the Hilbert space $\hat{V}$. Let $Z = L_2[0,T;V]$ and $Y = L_2[0,T;\hat{V}]$ be the function spaces corresponding to V and $\hat{V}$ defined on $[0,T]$. Here, $B : Y \to Z$ is a bounded linear operator , $f : [0,T] \times V \to V$ is a non linear operator, $A : D(A) \subset V \to V$ is a closed operator whose domain $D(A)$ is dense in V. The system (1) is said to be a.c. in the time interval $[0,T]$, if for every desired final state $x_T \in V$ and $\varepsilon > 0$ there exists a control function $u \in Y$, such that the solution $x_u(\cdot)$ of (1) satisfies $\| x_u(T) - x_T \| < \varepsilon$. In controllability literature, it is common to use Fixed point or De-

gree theory argument to establish a.c of the above semilinear control system, which makes it necessary to assume certain inequality conditions involving various system constants. These conditions are often difficult to verify for a given system. In this paper the a.c is proved using a direct approach, avoiding fixed point arguments for certain class of nonlinear functions f. The main assumption on f is that it satisfies negative monotonicity.

Controllability of neutral functional evolution integrodifferential systems with infinite delay. **Balachandran Krishnan** (Bharathiar University, Coimbatore, India) IC/CT4115/030

In this paper we establish a set of sufficient conditions for the controllability of neutral functional evolution integrodifferential systems in Banach spaces. This class of neutral equations serve as an abstract formulation of many partial neutral integrodifferential equations which arise in the applications of the theory of population dynamics, compartmental systems, viscoelasticity and many other fields of science. The controllability results are obtained by using the analytic semigroup theory and the Nussbaum fixed point theorem.

Carleman estimate for parabolic equation with memory effects and exact controllability. **Sakthivel Kumarasamy** (Bharathiar University, India) IC/CT1053/062

The result of this work concerns with the exact controllability to the trajectories for a nonlinear parabolic equation with memory effects of the form

$$y_t - \mu y_{xx} + y y_x - \int_0^t k(t-\tau) y_{xx}(\tau) d\tau = \chi_\omega(x) u \quad \text{in } (0,T)\times\Omega$$

with the homogeneous Neumann boundary data

$$\frac{\partial y}{\partial \nu} = 0 \quad \text{on } (0,T)\times\partial\Omega, \quad y(0,x) = y_0(x) \quad \text{in } \Omega,$$

where Ω is a nonempty open bounded and connected subset of $\mathbb{R}$ with smooth boundary $\partial\Omega$ of class C^2 and ν is the outword unit normal vector to the boundary $\partial\Omega$. Here $\mu > 0$ is a constant, χ_ω is the characteristic function of the open set $\omega \subset \Omega$, $y = y(t,x)$ is the state and $u = u(t,x)$ is the control function to be determined which acts on the system through ω. This model arises in a number of practical applications, for example, in the modeling of physical phenomena associated with heat flow in materials with memory and the models involving viscoelastic forces.

The proof relies on Kakutani's fixed point theorem and makes use of the null controllability results for the corresponding linearized system (with $\mu = 1$)

$$y_t - y_{xx} + a(t,x) y_x + b(t,x) y - \int_0^t k(t-\tau) y_{xx}(\tau) d\tau = \chi_\omega(x) u.$$

Here it is assumed that the coefficients a, b and the kernel k satisfy

$$a \in L^\infty((0,T)\times\Omega), \quad b \in L^\infty((0,T)\times\Omega) \quad \text{and} \quad k \in C^1[0,T], \quad k(0) = 0.$$

The global exact null controllability results for the above linear parabolic equation with memory is established as the limit of an approximation process, constructed with the aid of a family of optimal control problem for the linear system and the observability estimate which is the consequence of a Carleman inequality for the associated adjoint system.

Robust controllability of linear systems: analysis and application to pursuit problems. **Valery Glizer** (Technion – Israel Institute of Technology), Vladimir Turetsky (Technion – Israel Institute of Technology) IC/CT1352/030

Controllability, i.e. the ability to transfer a dynamic system from a given set of initial positions to a given target set by a proper choice of the control function, is one of the basic system properties. Controllability has been well studied for systems without uncertainties by using an open-loop control.

Unfortunately, this elegant theory is not always applicable to real-life systems because their dynamics is effected by unmeasurable components (uncertainties). For these systems, the controllability, robust with respect to any admissible uncertainty realization, should be studied. As a rule, the robust controllability is realized by a feedback control.

In this talk, a class of linear time-dependent controlled systems with additive input uncertainties (disturbances) is considered. The target set is a given linear manifold. For this system, necessary and sufficient robust controllability conditions are established.

It is important not only to know that a system is robustly controllable, but also to construct a proper class of feedback strategies realizing this controllability (transferring strategies). In this talk, a class of linear state-feedback transferring strategies is derived.

The general robust controllability concept does not take into account possible control constraints, although such constraints are indispensable part of most of practical control problems. Thus, the next step is to adapt the results on the robust controllability to the case of control constraints. This leads to the constructing a robust controllability set, i.e. the set of all initial positions, from which the robust transfer of the system to the target set is possible subject to the control constraints.

The theoretical results of this talk are applied to some pursuit problems arising in the aerospace engineering.

Complete controllability of perturbed stochastic integro-differential systems. **Karthikeyan Shanmugasundaram** (Bharathiar University, India) IC/CT4120/030

In this paper we examine the controllability of a semilinear stochastic integrodifferential system in finite dimensional spaces. This type of equations occur in population models where the integral term specifies how much weight attached to the population at varies past times, in order to arrive at their present effect on the resources availability. The complete controllability of such equations is of quite fundamental importance biologically when the parameters are subject to some random disturbances like environmental factors. The study of this phenomena has become an essential part of qualitative theory of stochastic differential equations. The results are obtained by using the Banach fixed point theorem and an example is provided to illustrate the technique.

Existence and uniqueness results for a nonlinear differential system. **Rodica Luca-Tudorache** (Technical University of Iaşi, Romania) IC/CT523/033

We investigate the existence, uniqueness and asymptotic behaviour of the strong and weak solutions to the nonlinear differential system

$$u_j'(t) + \frac{v_j(t)-v_{j-1}(t)}{h_j} + c_j A(u_j(t)) \ni f_j(t)\,,$$
$$v_j'(t) + \frac{u_{j+1}(t)-u_j(t)}{h_j} + d_j B(v_j(t)) \ni g_j(t)\,,$$

where $j = \overline{1,N}$, with $t \in [0,T]$ in H, with the boundary condition:

$$(v_0(t), -u_{N+1}(t), s_1 w_1'(t), \dots, s_m w_m'(t))^T \in$$
$$\in -\Lambda((u_1(t), v_N(t), w_1(t), \dots, w_m(t))^T),\ t \in [0,T]$$

and the initial data

$$u_j(0) = u_{j0}\,, \quad v_j(0) = v_{j0}\,, \quad j = \overline{1,N}$$
$$w_i(0) = w_{i0}\,, \quad i = \overline{1,m}\,,$$

where H is a real Hilbert space, $N \in \mathbb{N}$, $T > 0$, c_j, d_j, $h_j > 0$, $\forall j = \overline{1,N}$, and A, B are multivalued operators in H and Λ is a multivalued operator in H^{m+2}, which satisfy some assumptions.

This problem is a discrete version with respect to x (with $H = \mathbb{R}$) of some problems which have applications in integrated circuits modelling (see [4-6]), and it is a generalization of the case studied in [3]. For the proofs of our theorems we use several results from the theory of monotone operators and nonlinear evolution equations of monotone type in Hilbert spaces (see [1-2]).

A continuation method for positive bound state of N coupled nonlinear Schrödinger equation. **Yuen-Cheng Kuo** (National University of Kaohsiung, Taiwan) IC/CT1394/033

We develop a stability continuation method for the computation of positive bound states of time-independent, N coupled nonlinear algebra equation (NAE) which describe a N coupled nonlinear Schrödinger equation. The solution curve with respect to some parameter of the NAE is then followed by the proposed method. For a one component NAE, we develop a iterative method for computation of positive ground state solution. For a N coupled NAE, we prove that N identical positive bound states will bifurcate into N different positive bound states at a finite repulsive inter-component scattering length. Numerical results show that various positive bound states of a three-component NAE are solved efficiently and reliably by the continuation method.

Multiplicity results for quasi-linear problems. **Abdelrachid El Amrouss** (Université Mohammed Premier Oujda, Morocco) IC/CT886/033

Let us consider the nonlinear elliptic problem

$$(\mathcal{P}) \begin{cases} -\Delta_p u = f(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is a bounded domain in $\mathbb{R}^N$ with smooth boundary $\partial\Omega$, Δ_p is the p-Laplacian operator defined by $\Delta_p u := div(|\nabla u|^{p-2}\nabla u)$, $1 < p < \infty$ and $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function satisfying the subcritical growth

$$(f_0) \qquad |f(x,t)| \le c(1+|t|^{q-1}),\ \forall t \in \mathbb{R},\ \text{a.e x} \in \Omega,$$

for some $c > 0$, and $1 \le q < p^*$ where $p^* = \frac{Np}{N-p}$ if $1 < p < N$ and $p^* = +\infty$ if $N \le p$.

Applying an minimax arguments and Morse theory, we establish some results on the existence of multiple nontrivial solutions for a problem $\mathcal{P}$.

Kink-antikink nonlinear-wave collisions in a cubic Klein-Gordon equation: the n-bounce resonance and the separatrix map. **Richard Haberman** (Southern Methodist University, USA) IC/CT4335/030

We provide a detailed mathematical explanation of a phenomenon known as the two-bounce resonance observed in collisions between kink and antikink traveling waves, originally extensively investigated in the 1980s by Campbell and his collaborators.. Studying a finite-dimensional "collective coordinates" model, we use geometric phase-plane based reasoning and matched asymptotic expansions to explain the mechanism underlying the phenomenon. We derive the critical relative velocity below which the interacting kinks have complex behavior and compare it to new high-resolution numerical simulations. We derive a separatrix map that explains the complex fractal-like dependence on initial velocity for kink-antikink interactions. Joint work with Roy Goodman.

Finite dimensionality of the global attractor for a Klein–Gordon–Schrödinger equation. **Nikolaos Stavrakakis** (National Technical University of Athens, Greece), Poulou Marilena (National Technical University of Athens, Greece) IC/CT4750/033

In this talk we prove the existence and uniqueness of solutions for the following evolution system of Klein–Gordon–Schrödinger type

$$\begin{aligned} i\psi_t + \kappa\psi_{xx} + i\alpha\psi &= \phi\psi + f, \\ \phi_{tt} - \phi_{xx} + \phi + \lambda\phi_t &= -Re\psi_x + g, \\ \psi(x,0) = \psi_0(x),\ \phi(x,0) &= \phi_0(x),\ \phi_t(x,0) = \phi_1(x), \\ \psi(x,t) = \phi(x,t) &= 0,\ x \in \partial\Omega,\ t > 0, \end{aligned}$$

where $x \in \Omega$, $t > 0$, $\kappa > 0$, $\alpha > 0$, $\lambda > 0$, f and g are driving terms and Ω (bounded) $\subset \mathbb{R}$. Next, with the help of the energy equation we prove that the solutions of the system depend continuously on the initial data and as a consequence the existence of a global attractor. Finally, the finite dimensionality of the global attractor is studied. Actually by means of the Lyapunov exponents we give an upper bound for the Hausdorff and Fractal dimensions of the global attractor.

This work was partially financially supported by a grant from the Pythagoras Basic Research Program No. 68/831 of the Ministry of Education of the Hellenic Republic.

Control of noise-induced behavior in neural network. **Natalia Janson** (Loughborough University, UK), Sandhya Patidar (Loughborough University, UK) IC/CT4713/033

We study the effect of time-delayed feedback control on the noise-induced dynamics [1] of an ensemble of N globally coupled excitable neural oscillators, each being modeled by the FitzHugh–Nagumo system with independent Gaussian white noise source. Both coupling and feedback are introduced through the mean field. The effect of delayed feedback is studied both analytically and numerically.

For the theoretical study we exploit a method of [2] introduced in [3], which allows one to write down a closed system of cumulant equations for the mean values, variances and covariances of the system variables, under the assumption that their third and higher order central moments are relatively small.

IC/CTS4675/03: Model systems, diffusion, biological systems.

Organiser: Takeshi Sugimoto (Kanagawa University, Japan)

Bistable waves in discrete inhomogeneous media. **Brian Moore** (University of Iowa, USA), Antony Humphries (McGill University, Canada) IC/CT3186/036

Using a specific bistable nonlinearity for a spatially discrete Nagumo equation with inhomogeneous diffusion, one is able to derive explicit solutions by way of transform techniques and Jacobi operator theory. A topic of particular interest concerning this problem is the conditions that imply propagation failure of traveling wave solutions. By finding the steady state solutions, we derive necessary and sufficient conditions for traveling waves to become pinned due to variations in the diffusion coefficients.

On the structure of phase spaces in synergetic inter-representation network. **Takeshi Sugimoto** (Kanagawa University, Japan) IC/CT1051/036

Exchanging ideas and concepts among people can be handled with so-called Synergetic Inter-Representation Network. In this theory representations in our minds and outside ourselves constitute networks. The state in our mind, n-dimensional $\mathbf{x}$, is described by

$$\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} = \sum_{j=1}^{n} \left\{ \lambda_j - B \sum_{i=1,\ i\neq j}^{n} \left(\mathbf{v}_i^+ \cdot \mathbf{x}\right)^2 \right\} \left(\mathbf{v}_j^+ \cdot \mathbf{x}\right) \mathbf{v}_j - C|\mathbf{x}|^2 \mathbf{x},$$

where λ_j, B, C, $\mathbf{v}_j$ and $\mathbf{v}_j^+$ denote the growth rate of the jth representation, the discrimination rate, the noise-eliminating rate, the jth representation and its adjoint, respectively. The adjoining order parameter, ξ_j, is defined by $\mathbf{v}_j^+ \cdot \mathbf{x}$. Multiplying the governing equation of ξ_j by ξ_j and rewriting ξ_j^2 as η_j, we obtain

$$\frac{\mathrm{d}\eta_j}{\mathrm{d}t} = 2 \left\{ \lambda_j - (B+C) \sum_{i=1}^{n} \eta_i + B\eta_j \right\} \eta_j \text{ for } j = 1, 2, \cdots, n,$$

that is, n-dimensional Lotka-Volterra equations. This discovery allows us to scrutinize the existence and stability of the fixed points: 1. The origin is an unstable fixed point; 2. The single representation survival, for example $(0, 0, \cdots, \lambda_j/C, \cdots, 0)$, is a stable fixed point, if $\lambda_j/C > \lambda_i/(B+C)$ for all $i \neq j$; 3. The coexistence of several representations, for example $(\eta_1, \eta_2, \cdots, \eta_k, 0, \cdots, 0)$, exists as a saddle point, if

$$\lambda_j < \frac{B+C}{(k-1)B + kC} \sum_{i=1}^{k} \lambda_i \text{ for } j = 1, 2, \cdots, k.$$

If all of these exist, the number of the saddle points is $2^n - n - 1$.

In the presentation, I will display the four-dimensional phase space and the high-dimensional separatrices using the directed graph.

Feedback control of pattern formation. **Liam Stanton** (Northwestern University, USA), Alexander Golovin (Northwestern University, USA) IC/CT1470/036

A global feedback control of pattern formation in a wide class of systems described by the Swift-Hohenberg (SH) equation is investigated theoretically, by means of stability analysis and numerical simulations. Two cases are considered: (i) feedback control of the competition between hexagon and roll (stripe) patterns described by a supercritical SH equation, and (ii) the use of feedback control to suppress the blow-up in a system described by a subcritical SH equation. In case (i), it is shown that feedback control can change the hexagon and roll stability regions in the parameter space as well as cause a transition from up- to down-hexagons and stabilize a skewed (mixed mode) hexagonal pattern. In case (ii), it is demonstrated that feedback control can suppress blow-up and lead to the formation of spatially-localized patterns in the weakly nonlinear regime. The effects of a delayed feedback are also investigated for both cases, and it is shown that delay can induce temporal oscillations as well as blow-up.

Creative brain neuron dynamics simulated by the discrete 2D and 3D space-distributed logistic equation. **Vladimir Gontar** (Ben-Gurion University, Israel) IC/CT4231/036

Mathematical modeling of the brains neurons networks by the interconnected oscillators with chaotic regimes is one of the effective methods to simulate brain creativity in a form of artistic 2D images within their relation to the brain waves (EEG) [1].In this work we would like to present some new results on creative patterning based on exploiting dynamics of interconnected chaotic oscillators distributes on 2D and 3D lattices (LxL)and (LxLxL) where each cell designated by the integer coordinates i,j,k =1,2,ĚL and contain discrete dynamical system (chaotic oscillator in a form of logistic equation)and for 2D case: Xn+1(i,j)= pn(i,j)Xn(i,j)(1-Xn(i,j). Here parameter pn (i,j) = F(b, Xn-1 (i,j)) depend on the values Xn-1(i,j) distributed on 2D lattice and calculated for the previous to n discrete states (n-1,n=1,2,...) In the simplest case Xn-1(i,j) just the closest to the considered cell with coordinates (i,j) eight neighbors with coordinates (i,j) = (i-1,j-1; i+1,j;Ěi+1,j+1),(for the 3D lattice: 26 neighbors), F is an arbitrary chosen analytical function with the parameters b. It will be shown that discrete logistic equation can be used for generating colored symmetrical patterns within the interval 3.57=pn(i,j)=4. Variety of the patterns resulted from the proposed approach can be drastically increased by using different functions F, varying the parameters b and by using other types of basic difference equations with chaotic regimes[2]. References:[1] Gontar, V. (2004), The dynamics of living and thinking systems, biological networks and the laws of physics, Discrete Dynamics in Nature and Society, 8 (1).[2] Gontar, V., Grechko, O. (2006), Generation of symmetrical colored images via solution of the inverse problem of chemical reactions discrete chaotic dynamics, Int. J. Bifurcation and Chaos, 16(5).

Controlling chaos in nuclear-spin generator system using back-stepping design. **Ömür Umut** (Abant Izzet Baysal University, Turkey) IC/CT4292/030

In this study, I discuss how to control nuclear spin generator system by using backstepping design. Firstly, an active backstepping design control method is presented for synchronizing two identical nuclear spin generator system with each other. It is a systematic design approach and consists of a recursive procedure interlacing the choice of Lyapunov function with the design of active control. Secondly, backstepping design is proposed for controlling uncertain nuclear spin generator system based on parameter identification. To achieve this an effective observer is designed to identify the unknown parameter of nuclear spin generator system and track any desired trajectory. Finally, numerical simulations are provided to show the effectiveness and feasibility of the developed designs.

IC/CTS4678/03: Lyapunov stability.

Organiser: Stanislaus Maier-Paape (RWTH Aachen, Germany)

Obstacle avoidance by artificial potential fields with asymptotic-stability properties. **Jito Vanualailai** (University of the South Pacific, Fiji), Shin-ichi Nakagiri (Kobe University, Japan), Bibhya Sharma (University of the South Pacific, Fiji) IC/CT3414/038

A recent application of the Direct Method of Lyapunov is one that deals with the geometric problems of finding a collision-free path for a moving solid object among other solid objects. This problem, which is called the "find path problem," is well-known in robotics and several ways of generating solutions have been proposed. Among the more theoretically elegant but computationally intensive algorithms are those that are based on some kind of graph search methods or geometric search algorithms. Basically, graph search methods seek to establish straight lines or connectivity graphs that allow obstacles to ŚseeŠ each otherŠs position, shape, and orientation.

Simpler algorithms tend to use physical analogies. In 1986, a potential field method was proposed by Khatib. In his approach, position-dependent artificial potential fields are placed around obstacles and collision-free can be generated by determining the number of repulsive and attractive poles. Many improvements to KhatibŠs method have been proposed since then. More recently, Tanner et al. (2003) proposed a novel artificial potential method based on inverse Lyapunov functions to control nonholonomic mobile manipulators.

It is also well-known however that the artificial potential methods have a major drawback, namely, the potential function may have local minima other than the goal configuration. This leads to the possibility of having a collision-free path leading not to the goal but to "traps" outside the target.

This paper proposes a point-mass obstacle avoidance system that is asymptotically stable, which means that the potential function - indeed, the Lyapunov function - of the system has no local minima other than the goal configuration in the pathwise-connected proper subset of free space which contains the goal configuration.

Reduction problems in multi-scale systems dynamics. **Lyudmila Kuzmina** (Kazan Aviation Institute, Russian Federation) IC/CT3943/038

The paper is devoted to the different aspects of mathematical modelling and qualitative analysis in dynamics of complex multi-scale systems, that are generated by applied problems of engineering practice. Main aims are the problems of optimal mechanical-mathematical modelling and the regular schemes of decomposition in engineering design. The generalization of the reduction principle, well-known in stability theory of A.M. Lyapunov, is important goal of engineering practice. A uniform methodology, based on Lyapunov's methods, in accordance with Chetayev's stability postulate, is developed. The presented approach, based on a combination of stability theory and perturbation theory methods, allows us to elaborate the general conception of the modelling, to work out the simple schemes of engineering level for decomposition-reduction of full systems and dynamic properties. This approach enables us to obtain simplified models that are of interest for applications, with rigorous substantiation of the acceptability. The conditions of qualitative equivalence between full and reduced models are determined, with extended estimations of N.G. Chetayev's type on infinite time interval. In the applications to multi-scale systems dynamics (for mechanical systems with gyroscopes, for electromechanical systems, for robotic systems,...) the obtained results enable us to construct the reduced models in a strict mathematical way. The interpretation of these formalized constructions (reduced models) leads to new approximate theories, acceptable in applications of engineering practice. It allows to optimize the analysis process and synthesis, to cut down the engineering design time. As applications various examples of concrete physical nature are considered.

Stability of perturbed dynamical systems. **Hammami Mohamed Ali** (University of Sfax, Tunisia) IC/CT825/003

We consider a time-varying nonlinear perturbed dynamical system. Under some growth sufficient conditions on the nominal system, we give a stability result of the system with perturbation. The exponential and uniform asymptotic stability are studied. A new Lyapunov function is also introduced to abtain a large class of stable systems.

A navigation and collision-avoidance scheme for heterogeneous robot collectives. **Bibhya Sharma** (University of the South Pacific, Fiji), Jito Vanualailai (University of the South Pacific, Fiji) IC/CT665/038

In this paper we propose a set of new continuous time-invariant acceleration controllers that considers the multi-task of control and motion planning of heterogeneous robot collectives within a dynamic but constrained environment. The dynamic obstacles will include members of the collective as well as other moving solids in the workspace. An dual avoidance scheme is introduced for a heterogenous 3-robot collective and the moving/static obstacles within a potential field framework. This, together with the other kinematic and the dynamics constraints have been treated simultaneously via a Lyapunov-based approach. We demonstrate the efficiency of the nonlinear algorithm with results through simulations of a couple of interesting situations.

Lyapunov's second method in problems of the stability of solutions of systems with impulse effect. **Alexander Ignatyev** (Donetsk, Ukraine) IC/CT4236/038

A system of ordinary differential equations with impulse effect at fixed moments of time is considered. The system is assumed to have the zero solution. It is shown that the existence of a corresponding Lyapunov function is a necessary and sufficient condition for the uniform asymptotic stability of the zero solution. Restrictions on perturbations of the right-hand sides of differential equations and impulse effects are obtained under which the uniform asymptotic stability of the zero solution of the 'unperturbed' system implies the uniform asymptotic stability of the zero solution of the 'perturbed' system.

Stability analysis of two-dimensional pool-boiling systems. **Stanislaus Maier-Paape** (RWTH Aachen, Germany) IC/CT4885/035

In this talk a model for pool-boiling systems is considered. This model involves only the temperature distribution within the heater and models the heat exchange with the boiling medium via a nonlinear boundary condition imposed on the fluid–heater interface. The model allows multiple homogeneous (i.e. spatially constant) and multiple heterogeneous steady-state solutions. The structure of this family of steady-state solutions has been studied by means of a bifurcation analysis in two recent papers by Speetjens, Reusken and Marquardt. The present study concentrates on stability properties of these steady-state solutions. To this end, a generic linear and a case-specific nonlinear stability analysis are performed which show that only the homogeneous steady-states of complete nucleate or complete film boiling are linearly stable. All heterogeneous steady-state solutions appear linearly unstable. These stability results are consistent with laboratory observations.

03: Nonlinear Analysis and Dynamical Systems, Posters

IC/PP852/030: **Control of the symmetric ball rolling without sliding or spinning.**

Presenter: Sebastián José Ferraro (Universidad Nacional del Sur, Argentina)
Co-author: Maria Etchechoury (Universidad Nacional de La Plata, Argentina)
Co-author: Hernan Cendra (Universidad Nacional del Sur, Argentina)

A ball having two of its three moments of inertia equal and whose center of mass coincides with its geometric center, is called a *symmetric ball*. The symmetric ball rolling without sliding or spinning on a horizontal floor is an interesting example of a nonholonomic system. The *dynamics* of this system has been thoroughly described in terms of Liouvillean functions (see *Rolling of a symmetric sphere on a horizontal plane without sliding or spinning*, Rep. Math. Phys. vol. 57, no. 3, 2006, and references therein). This is done using a geometric approach, the system is shown to be equivalent to a dynamical system on $S^2 \times S^1$. On the other hand, the *isoholonomic problem* for a massless ball rolling without sliding or spinning has been also recently studied, emphasizing the geometry of the problem (see *A nonholonomic approach to isoparallel problems and some applications*, Dyn. Syst. vol. 21, no. 4, 2006, and references therein). The so-called *plate-ball system* is one mechanism that allows to implement this kind of optimal control problem. In the present poster we perform a geometric study of the control of the symmetric ball, using results from the two previous references. In this case we use impulsive control. Numerical methods are also addressed.

IC/PP4797/030: **Multiple-delay feedback control.**

Presenter: Ulrich Parlitz (Universität Göttingen, Germany)
Co-author: Alexander Ahlborn (Universität Göttingen, Germany)

Multiple Delay Feedback Control (MDFC) with two, three or four different and independent delay times is used to stabilize steady states of various chaotic dynamical systems. A comparison with delayed feedback control methods that are based on a single (fundamental) delay time (Pyragas' TDAS, ETDAS) shows that MDFC is more effective for fixed point stabilization in terms of stability and flexibility, in particular for large delay times. This control method is also used for manipulating spatio-temporal chaos based on lumped local feedback with several different delay times. As illustrated with the two dimensional Ginzburg-Landau and the Fitzhugh-Nagumo equation MDFC can, for example, be used to suppress turbulent fluctuations, to convert chaotic spiral waves into guided plane waves and for trapping spiral waves.

IC/PP862/030: **Multiparametric frequency-domain criteria for stability of distributed systems with multiple equilibria.**

Presenter: Aleksey Perkin (Saint Petersburg State University of Architecture, Russian Federation)
Co-author: Vera Smirnova (Saint Petersburg State University of Architecture, Russian Federation)

We study the asymptotic behavior of distributed nonlinear control systems which can be described by integral Volterra equations of the type:

$$\sigma(t) = \sigma_0(t) - \int_0^t \gamma(t-\tau)\varphi(\sigma(\tau))\,\mathrm{d}\tau \qquad (t \geq 0)\,. \qquad (1)$$

Here the function $\sigma_0(t)$ describes the proper oscillations of the system and $\gamma(t)$ is its impulse transfer function. Two types of the system are considered. The first type includes the systems with a *stable* linear part; i.e., $\sigma_0(t), \gamma(t) \in L_1[0,+\infty) \bigcap L_2[0,+\infty)$ and with piecewise continuous nonlinear function φ which satisfies the sector condition $0 \leq \varphi(\sigma)\sigma \leq k\sigma^2$ $(k < +\infty)$. Systems of the second type have *critical* linear part; i.e., $\sigma_0(t) = \nu + \sigma_1(t)$, $\gamma(t) = \gamma_0 + \gamma_1(t)$ where ν, $\gamma_0 \in R$ and $\sigma_1(t)$, $\gamma_1(t) \in L_1[0,+\infty) \bigcap L_2[0,+\infty)$. Another feature of the second type is the periodicity of the nonlinear function. Systems of both types often have a non-unique equilibrium. Several new theorems are demonstrated which guarantee that every solution of the above equation tends to certain equilibrium as t tends to infinity. The theorems are proved by means of the method of *a priori* integral estimates, which is widespread in control theory[1].

The results are formulated in terms of the transfer function

$$\chi(p) = \int_0^\infty \gamma(t)e^{-pt}\,\mathrm{d}t \qquad \text{for } (p \in \mathbb{C})\,.$$

They have the form of frequency-domain inequalities. Thus, for systems of the first type (provided that certain restrictions on φ and χ are fulfilled) the following assertion is true. If there exist such non-negative values of parameters τ, ϑ, and ϱ the inequality

$$\Re\{(\tau + i\omega\vartheta + \varrho\omega^2)\chi(i\omega)\} > 0$$

holds for all $\omega \neq 0$, then any solution of the Volterra equation tends to an equilibrium as $t \to +\infty$.

New frequency-domain inequalities presented in the paper are generated with regard to additional differential properties of nonlinear functions. As a result, either the inequalities are supplied by additional varying parameters or the algebraic restrictions on varying parameters are weakened. Perfecting the frequency-domain criteria leads to improved estimates for boundaries of convergence domains in the space of system parameters.

IC/PP4325/030: Mel'nikov–Samoilenko adiabatic stability problem.

Presenter: Yarema Prykarpatskyy (Akademia Górniczo-Hutnicza, Poland)

We develop a symplectic method for the investigation of invariant submanifolds of nonautonomous Hamiltonian systems and ergodic measures on them. The so-called Mel'nikov-Samoilenko problem for the case of adiabatically perturbed completely integrable oscillator-type Hamiltonian systems is studied on the basis of a new construction of "virtual" canonical transformations.

IC/PP3284/032: Mathematical and physical modelling of seismic faults.

Presenter: Alejandro Munoz-Diosdado (Insituto Politecnico Nacional, Mexico)

Modelling of seismic faults by using spring block systems on a frictional surface, requires to solve coupled differential equation systems with a great number of equations, in order to avoid this problem, the spring-block model is mapped into a continuous, non-conservative cellular automaton. In this work we analyse the models of Olami, Feder and Christensen (OFC) and Barriere and Turcotte (BT), those models can be used to mimic the dynamics of a seismic fault in two dimensions. We have in the OFC model two rigid plates that move relatively between them, the total force in each block is increased uniformly, until a site reaches a value limit and a relaxation process begins. The redistribution of the forces in the nearest-neighbor blocks, causes a chain reaction (synthetic earthquake). Every time the automaton is calculated a synthetic earthquake is obtained. We obtained catalogues of synthetic earthquake magnitude, which we can represent as a time series. Such series exhibit power law behavior so much for the magnitudes (Gutenberg-Richter law) as for the duration times. The analysis of these time series with methods of the non-linear dynamics provides interesting results; for example, the time series show multifractality for large values of the conservation level. We present variations of the original model to include the concept of asperity, they are regions on the seismic faults which can accumulate a great quantity of energy, when they broke they can give rise to earthquakes of great magnitude. The BT model is a fractal automaton model for modelling earthquakes; we study with this model foreshocks and aftershocks. Also in this model we obtain empirical relationships from real seismicity as the Gutenberg-Richter and the Aki law. Although these models are a great simplification for studying the dynamics of a real fault, they have properties that are related to real seismicity. They are interesting mathematical and physical applications to the study of earthquakes.

IC/PP4796/032: Cluster weighted modelling.

Presenter: Ulrich Parlitz (Universität Göttingen, Germany)
Co-author: David Engster (Universität Göttingen, Germany)

Cluster Weighted Modeling was first introduced by Gershenfeld et al. and combines density estimation of the input data with a functional relationship to the output data. This leads to a number of local clusters, each containing its own model for describing the observed data. The parameters are optimized using an Expectation-Maximization (EM) algorithm, leading to a local optimum in parameter space. Applications of Cluster Weighted Modelling to different forcasting and learning tasks are presented and evaluated, including modifications and extensions of the original algorithm.

IC/PP4960/028: Classical field theories with non-holonomic constraints.

Presenter: Joris Vankerschaver (Universiteit Ghent, Belgium)

Nonholonomic constraints in mechanics have a long and distinguished history, and have been the subject of renewed interest during the last decades. On this poster, we give an outline of the status of nonholonomic constraints in *classical field theories*: first of all, we establish a differential-geometric framework for such theories by extending some well-known methods from geometric mechanics. Secondly, we outline a physical example of a nonholonomic field theory. Finally we show how the underlying differential geometry may be exploited for the construction of geometric integration algorithms, and we discuss the accuracy of these methods.

IC/PP1077/036: A modelling approach to nutrient driven regime shifts in shallow coastal systems: competition between seagrass and macroalgae.

Presenter: Jose-Manuel Zaldivar Comenges (Joint Research Centre, Italy)

Pristine coastal shallow systems are considered as dominated by extensive meadows of seagrass species, which are assumed to take advantage of nutrient supply from sediment. An increasing nutrient input is thought to favour in a first phase phytoplankton and/or epiphytic micro-, macroalgae as well as opportunistic ephemeral macroalgae that coexist with seagrasses. The primary cause of shifts and succession in the macrophyte community are nutrients added to water, mainly nitrogen and phosphorus. A competition model between rooted seagrass and macroalgae has been developed to analyse the succession of primary producer communities in coastal lagoons and to analyse the characteristics of regime shift using bifurcation analysis. The model considers nutrient dynamics as well as shadowing effects.

IC/PP4945/038: Lyapunov stability of elliptic periodic solutions.

Presenter: Jifeng Chu Jifeng Chu (Tsinghua University, PR China)

Using the relation between the Hill's equations and the Ermakov–Pinney equations, we will given some interesting lower bounds of rotation numbers of Hill's equations. Based on the Birkhoff normal forms and the Moser twist theorem, we will prove that two classes of nonlinear, scalar, time-periodic, Newtonian equations will have twist periodic solutions, one class being regular and another class being singular.

IC/PP4874/038: Sufficient conditions for existence and approximate construction of forced periodic solutions in automatically controlled systems with hysteresis feedback.

Presenter: Michael Semenow (Russia)
Co-author: Anton Gulin (Novo Lipetsk, Russian Federation)
Co-author: Aleksandr Butov (Steklov Institute of the RAS, Russian Federation)
Co-author: Pasha Tolokonnikov (Tolokonnikov Pasha, Russian Federation)

Automatic controlled systems with the hysteresis feedback are studied in this paper. Dynamics of such systems is described by the set (system) of equations:

$$\dot{\mathbf{z}} = \mathbf{A}\mathbf{z} + \mathbf{b}u(t)\,, \tag{1}$$
$$u(t) = f(t, x(t), \xi(t))\,, \tag{2}$$
$$x(t) = (\mathbf{z}(t), \mathbf{c})\,, \tag{3}$$
$$\xi = l(\omega(t))\,, \tag{4}$$
$$\omega(t) = \Gamma[\omega_0]x(t)\,, \tag{5}$$

where $\mathbf{A}$ is a constant matrix with the dimension $n \times n$, $\mathbf{z}(t)$ - vector function with values in $\mathbb{R}^n$, $\mathbf{b}$, $\mathbf{c}$-fixed vectors from $\mathbb{R}^n$. Function $u = f(t, x, \xi)$ is supposed to be continuous on a population of variables and T-periodic one by the first argument. Equations (4)–(5) describes relations between entrance condition and result condition in some hysteresis converter.

The sufficient conditions of the existens and method of the approximate construction of the forced periodic solutions in system (1)–(5) are offered in this paper.

IC/PP1211/015: Robust analysis of discrete linear shift-invariant systems represented by an interval matrix.

Presenter: Juan Delgado-Romero (Instituto Tecnologico de Morelia, Mexico)

In this paper we describe a new bond in order to guaranteed the robust stability of a linear shift invariant system which is represented by an interval matrix. This bound is based in the bound of Juang. The uncerteinties are represented by an interval matrix. The system is represented in state variable with parametric uncertainty in the A matrix.

Let the interval matrix A, where $A = [L, U]$ and L and $U \in R^{n\times n}$, $A_0 = \frac{1}{2}(U - L)$ is the centroid matrix and $D = \frac{1}{2}(U - L)$ is the difference matrix, then the interval matrix is Schur stable if

$$\rho(A) \leq \rho(A_0) + \rho(\left|S\left(T_{re}^{-1}A_0T_{re}\right)\right|) + \left|T_{re}^{-1}\right| D\,|T_{re}| = \beta < 1$$

This paper is in collaboration with Prof. Rodolfo González-Garza.

IC/PP398/015: A chaotic–dynamic view of investment risk in emerging economies.

Presenter: Edgardo Jovero (Universidad Complutense de Madrid, Spain)

An open-economy neo-Keynesian model is developed which highlights market power and price-setting behavior as a source of the indeterminacy and structural instability characterizing the risk environment in emerging markets. This should explain why countries, which constitute the whole of the emerging economies as a group, provide different country investment risks individually.

This structural instability in the behavior of emerging countries can take the form of a Hopf bifurcation, the likelihood of which increases as the mark-up power increases. Evidence is presented as to the likelihood of a Hopf bifurcation occurring, using the qualitative geometric theory of nonlinear complex dynamical systems. The Keynesian view that structural instability globally exists in an emerging market economy is put forward, and therefore the need arises for policy to alleviate this instability in the form of dampened fluctuations is presented as an alternative view analyzing the nature of risk and its role in investment management.

MSC (2000) : 91B62 (mathematical economics), 37F45 (complex dynamical systems) PACS code: 89.67.Gh (economics, econophysics) JEL classification: F43 (economic growth of open economies) Keywords: risk, foreign capital, emerging markets, neo-Keynesian economics, Hopf bifurcation

04: Partial Differential Equations, Minisymposia

IC/MP93/004: Anisotropic curvature flow and its applications.

Organiser: Piotr Rybka (Uniwersytet Warszawski, Poland)
Co-organiser: Yoshikazu Giga (University of Tokyo, Japan)

In the theory of crystal growth the anisotropy plays an important role in the development of complicated patterns. In image processing several evolution equations are used to remove noise from images. Sometimes equations with anisotropic structure are more suitable for this purpose.

This minisymposium encompasses several topics related to partial differential equations (PDEs) whose structure is anisotropic. The derivation of models as well as mathematical and numerical analyses of the equations are within the scope of the session. There is a special emphasis on interface evolution equations with singular interfacial energy as well as total variation flow because they are related to each other. The feature of these equations is that the speed of evolution is determined by nonlocal quantities so, strictly speaking, it is not a PDE although it is considered as a limit of PDEs.

As a typical example we consider crystal growth from vapor or solution whose equilibrium shape has flat parts called facets. Another example is crystalline motion of surfaces which is less studied compared with motion of curves. As far as the crystal growth problem is concerned we are particularly interested in the problem whether or not a facet breaks during evolution. For a total variation flow which is very related to crystalline motion such a problem is also important. Because of the nonlocal nature of these problems the analysis of these equations is not conventional and several new ideas are necessary.

In this minisymposium we discuss these problems both from analytic and numerical point of view. Several analytic tools, including variational method, viscosity method and others are needed. Numerical approach includes a level set approach as well as other methods. However, we do not intend to exclude other kind of anisotropy which is useful to study crystal growth or image processing.

Anisotropic line tension for a step edge on an epitaxial surface. **Russel Caflisch** (University of California, Los Angeles, USA) IC/MT2073/004

This talk starts with an atomistic model for the dynamics of a step edge (or island boundary) on an epitaxial surface. A steady state solution is found through a kinetic balance rather than local equilibrium and is validated by comparison to KMC simulations. In the limit of large adatom diffusion rate, the resulting boundary condition at the step edge involves a line tension term that is consistent with the Gibbs-Thomson formula. This is an atomistic, kinetic derivation of the Gibbs-Thomson formula, in contrast to the usual derivation from a thermodynamic driving force.

Singular interfacial energy and faceting in epitaxial relaxation. **Dionisios Margetis** (Univ. Maryland at College Park, USA) IC/MT1028/004

At sufficiently low temperatures surfaces of crystalline materials have a continuum free energy density that is singular at high-symmetry surface orientations. This lack of smoothness originates from the existence of distinct line defects, "steps", on crystal surfaces. From the continuum standpoint, when crystal surfaces relax to become flat by surface diffusion, the energy density singularity gives rise to macroscopically flat surface regions, "facets". More generally, the use of an interfacial energy suggests a steepest-descent, “variational” treatment of facet motion.

In this talk I address the question: Is this “variational” approach the continuum limit of a physically reasonable, discrete step flow model? By adopting the view that facet edges are free boundaries I show that, in principle, the crystal microstructure affects macroscopic evolution through the motion of individual steps on top of facets. In particular, the collapse times of such steps enter the requisite boundary conditions for the continuum. I discuss the crucial role of step interactions by application of perturbation theory.

A new look on singular flows. **Piotr Mucha** (Uniwersytet Warszawski, Poland) IC/MT3953/004

The subject of our analysis is a parabolic system arising from the theory of singular curvature flows. Our model is a simplification of the original equation in the plane with an anisotropic energy density function whose Wulff shape is a square. Due to this fact the system becomes degenerated and singular. Our main goals are the well posedness and the precise qualitative analysis of the solutions we constructed. As a result we obtain a possible interpretation of the product of two Dirac’s deltas.

Presented results are a joint work with Piotr Rybka from Warsaw University.

A simple case of the driven singular mean curvature flow in the plane. **Piotr Rybka** (Uniwersytet Warszawski, Poland), Yoshikazu Giga (University of Tokyo, Japan) IC/MT1396/004

In many free boundary problems (FBPs) the interface evolves according to the Gibbs-Thomson law with kinetic undercooling. We have in mind growth of ice from vapor or growth of crystals from solution. Mathematically, the Gibbs-Thomson relation is a driven mean curvature flow for the interface. In the problems mentioned above the underlying surface energy density function γ is of poor regularity, hence we are lead to consider singular mean curvature. The driving term is the coupling to the diffusion field (e.g. supersaturation or temperature). However, in the present problem, we assume that it is given and enjoys some monotonicity property, which is valid in the full FBP.

We study the dynamics of the driven singular mean curvature flow in the plane if function γ is piecewise linear and its Wulff shape of a rectangle. We are mostly interested in the evolution of closed Lipschitz curves which are slight perturbations of rectangles. We show existence of solutions for a generic driving satisfying the mentioned above monotonicity property. However, our focus is the process of bending of initially flat facets.

The motivation for the present choice of the Wulff shape comes from the fact that a rectangle is a cross-section of a circular cylinder (which is an aproximation to a hexagonal prism being the equilibrium shape of ice) with a plane containing the symmetry axis.

IC/MP93/004: Anisotropic curvature flow and its applications. #2

Organiser: Piotr Rybka (Uniwersytet Warszawski, Poland)
Co-organiser: Yoshikazu Giga (University of Tokyo, Japan)

(For abstract, see session #1 above.)

Some diffusion equations with finite propagation speed. **José Mazón** (Universitat de València, Spain) IC/MT1954/004

To correct the infinite speed of propagation of the classical diffusion equation Ph. Rosenau proposed the tempered diffusion equation

$$u_t = \nu \operatorname{div}\Big(\frac{uDu}{\sqrt{u^2 + \frac{\nu^2}{c^2}|Du|^2}}\Big).$$

This equation was derived by Y. Brenier by means of Monge-Kantorovich's mass transport theory and he named it as the *relativistic heat equation*.

We prove existence and uniqueness of entropy solutions for the Cauchy problem for the quasi-linear parabolic equation $u_t = \operatorname{div}\mathbf{a}(u,Du)$, where $\mathbf{a}(z,\xi) = \nabla_\xi f(z,\xi)$ and f being a function with linear growth as $\|\xi\| \to \infty$, satisfying other additional assumptions. In particular, this class includes the relativistic heat equation and the some flux limited diffusion equation used in the theory of radiation hydrodynamics.

We also study the evolution of the support of entropy solutions of relativistic heat equation. We establish the following result.

Proposition *Let C be an open bounded set in $\mathbb{R}^N$. Let $u_0 \in (L^1(\mathbb{R}^N) \cap L^\infty(\mathbb{R}^N))^+$ with support equal to $\overline{C}$. Assume that given any closed set $F \subseteq C$, there is a constant $\alpha_F > 0$ such that $u_0 \geq \alpha_F$ in F. Then, if $u(t)$ is the entropy solution of the Cauchy problem for the relativistic heat equation with u_0 as initial datum, we have that:*

$$\operatorname{supp}(u(t)) = \overline{C} \oplus \overline{B_{ct}(0)} \quad \text{for all } t \geq 0.$$

Singular diffusivity and its applications. **Mi-Ho Giga** (University of Tokyo, Japan), Yoshikazu Giga (University of Tokyo, Japan) IC/MT2896/004

Equations with singular diffusivity is by now popular. Typical examples include crystalline flows in material sciences and total variation flows in image processing. It is also useful to calculate the graph of discontinuous viscosity solutions for evolution equations by a level set method, where the graph of solutions are regarded as evolving surfaces.

However, its analytic foundation has not yet well established. We consider a class of first order evolution equations whose solutions may develop jump discontinuities. We introduce a singular vertical diffusivity in our level set formulation and study whether or not its level set (which is expected to be the graph of solutions) is overturned. By formal analysis there is a threshold magnitude of singular diffusivity to prevent overturning if the magnitute is greater than the threshold value.

Anisotropic variational problems in imaging. **Martin Rumpf** (Universität Bonn, Germany) IC/MT3096/004

In this talk applications of anisotropic geometric evolution equations and anisotropic variational problems will be discussed. Thereby, sharp edges or corners can be explicitly encoded in PDE models in imaging. A local classification identifies certain anisotropies or singularities in 2D or 3D images. This classification is then encoded in suitable a anisotropic energy integrant and a gradient flow is applied to relax the resulting functional. The classification can be done *a priori* or in a joint approach directly incorporated in the variational approach. Particular applications are the extraction of rectangular cartoons pattern for aerial images of city regions, the restoration or 3D-MR-Angiography data, or the restoration of surfaces.

A variational formulation for a level-set representation of multiphase flow and area-preserving curvature flow. **Peter Smereka** (University of Michigan, Ann Arbor, USA) IC/MT5064/004

Variational descriptions for various multiphase level-set formulations involving curvature flow are discussed. A representation of n phases using $n-1$ level set functions is introduced having the advantage that constraints preventing overlaps or vacuum are not needed. The representation is then used in conjunction with our variational formulation to deduce a novel level set based algorithm for multiphase flow. In addition, a similar variational formulation is applied to area preserving curvature flow. In this flow, the area (or volume in 3D) enclosed by each level set is preserved. Each algorithm has been implemented numerically and the results of such computations are shown.

IC/MP97/015: Viscosity solutions of partial differential equations: recent advances and applications.

Organiser: Pierpaolo Soravia (Università degli Studi di Padova, Italy)
Co-organiser: Martino Bardi (Università degli Studi di Padova, Italy)

The theory of viscosity solutions provides the correct framework and a powerful toolbox for treating a number of 1st and 2nd order partial differential equations that are not in divergence form, especially Hamilton–Jacobi equations and quasi-linear or fully nonlinear degenerate elliptic or parabolic equations. Many applied problems can be studied with these methods, such as deterministic and stochastic optimal control and games, motion of interfaces, crystal growth, vision theory, Hamiltonian mechanics etc. [1,2,3,4,5]. The goal of this minisymposium is reporting some recent advances in the viscosity solutions theory and its applications. Main topics on which the minisymposium will focus are: front propagation with prescribed normal velocity, in particular problems with non-local terms, with singularities and discontinuities; homogenization of nonlinear PDEs with highly oscillating terms, including stochastic oscillations and singular perturbation problems for the dimension reduction of multiple scales systems.

A level-set method for viscosity solutions with shocks. **Yoshikazu Giga** (University of Tokyo, Japan), Mi-Ho Giga (University of Tokyo, Japan) IC/MT2090/015

Solutions of first order equations or second order parabolic equations may develop jump discontinuities in finite time even if initial data is smooth. If the equation of first order is a conservation type like the Burgers equation, there is a notion of a weak solution called an entropy solution. A viscosity version describing a discontinuous solution was introduced several years ago. We note such a notion is applicable to some second order equations.

We further develop a level set method to describe motion of such discontinuous solution. For more practical purpose we introduce vertical singular diffusion term which prevents overturing of the graphs. This way is very convenient to calculate numerically by a level set method for the graph of discontinuous solutions.

The eqautions we studied has arised naturally from a crystal growth problem such as bunchings.

Recent results on dislocations dynamics and homogeneization. **Regis Monneau** (Ecole Nationale des Ponts et Chaussées, France) IC/MT1068/015

We will present two models describing the collective behaviour of dislocations defects in crystals. These models are mathematically written either as non-local Hamilton-Jacobi equations, or a coupled system of Hamilton-Jacobi equations. For these two systems, we will present homogenization results, describing at large scales the effective behaviour of densities of dislocations. As a by-product of our work, we will present rigorous results of homogeneization for a one-dimensional system of particules in interactions, as the number of particules goes to infinity.

Ergodic problem and periodic homogenization in half-space-type domains. **Francesca Da Lio** (Università degli Studi di Padova, Italy) IC/MT1833/015

We present some results related to the homogenization and ergodic problems for fully nonlinear elliptic boundary value problems in halph-space type domains with nonlinear Neumann boundary conditions. In particular we are interested in problems for which it is necessary to identify both the homogenized equation and boundary conditions.

Rates of convergence for the homogenization of fully-nonlinear second-order PDE in mixing random media. **Panagiotis Souganidis** (University of Texas at Austin, USA) IC/MT3798/015

I present new error estimates for the homogenization of second-order PDE in random mixing media with an algebraic rate. For linear equations the rate is algebraic while for fully nonlinear equations the rate is logarithmic.

IC/MP97/015: Viscosity solutions of partial differential equations: recent advances and applications. #2

Organiser: Pierpaolo Soravia (Università degli Studi di Padova, Italy)
Co-organiser: Martino Bardi (Università degli Studi di Padova, Italy)

(For abstract, see session #1 above.)

A new class of HJ equation with application to differential games. **Pierre Cardaliaguet** (Université Brest, France) IC/MT1460/015

In some two-player zero-sum differential games with asymetric information the value of the game—which depends on some parameter p in a convex way—turns out to be a viscosity subsolution of some HJ equation while its Fenchel conjugate w.r. to p is subsolution of a dual HJ equation. We show that these two conditions characterize the value. We also explain how approximate it and find explicit (Lax-Hopf) formulae.

Maximum principles for fully nonlinear elliptic and parabolic equations. **Andrzej Swiech** (Georgia Institute of Technology, USA) IC/MT2057/015

We will present various versions of generalized Alexandrov-Bakelman-Pucci (ABP) maximum principle for viscosity solutions of fully nonlinear elliptic and parabolic equations with superlinear-growth gradient terms and unbounded coefficients. The maximum principle may not hold for such equations however we will identify classes of equations for which some form of ABP maximum principle does hold. The results are obtained using the so called iterated comparison function method.

On the asymptotic behavior of solutions of p-Laplace equations as p goes to ∞. **Paola Loreti** (Universita' degli Studi di Roma "La Sapienza", Italy) IC/MT1163/015

Let $\Omega \subset \mathbb{R}^n$ be a bounded open set and $f \in C(\overline{\Omega})$. We consider, for $1 \ll p < \infty$ and $u \in W_0^{1,p}(\Omega)$, the following inhomogeneous p-Laplace equation:

$$\sum_{i=1}^{n} \frac{\partial}{\partial x_i}\Big(|Du(x)|^{p-2} \frac{\partial u(x)}{\partial x_i} \Big) = -f(x) \quad \text{in } \Omega .$$

with 0-Dirichlet boundary conditions; i.e.,

$$u(x) = 0 \quad \text{for } x \in \partial\Omega .$$

We consider the problem of the asymptotic behaviour of solutions as p goes to ∞.

The case where $n = 2$ and f is a positive constant corresponds asymptotically to a model having a torsional creep phenomenon for a prismatic elastoplastic rod.

The more general case $f > 0$ is studied in [1], and the limit of the sequence is the distance function from the boundary of Ω. Then, it is possible to generalize the result to the region ω where f vanishes, to non-negative functions f, by using an ∞-Laplace equation. Here we discuss some cases when f may change sign.

We also discuss about some properties of the maximizers for the functional $\int_\Omega f(x)v(x)\,dx$ in the space of functions $v \in C(\overline{\Omega}) \cap W^{1,\infty}(\Omega)$ satisfying $v|_{\partial\Omega} = 0$ and $\|Dv\|_{L^\infty(\Omega)} \le 1$, and about the connection between the above arguments.

The talk is based on a joint work with H. Ishii[2].

Viscous Hamilton–Jacobi equations. **Alessio Porretta** (Universita' di Roma Tor Vergata, Italy) IC/MT5069/015

IC/MP260/015: Applied mathematics in Latin America: part 1.

Organiser: Domingo Tarzia (CONICET - Univ. Austral, Rosario - ARGENTINA)
Co-organiser: Julio Claeyssen (Universidade Federal do Rio Grande do Sul, Brazil)

The goal of this minisimposium (Part 1) is to give an overview of the state of the art in diferent subjects related to partial differential equations, optimization and optimal control that are under current development in several regions of Latin America.

Numerical solution of a minimax ergodic optimal control. **María Soledad Aronna** (Universidad Nacional de Rosario, Argentina), Laura Aragone (Universidad Austral de Rosario, Argentina), Pablo Lotito (UNICEN de Buenos Aires, Argentina) IC/MT584/015

We consider an L^∞ minimax ergodic optimal control problem with cumulative cost. More precisely, we want to minimize the cost

$$J(x,\alpha) = \operatorname{ess\,sup}_{t\in[0,\infty)} \left\{ h(y(t),\alpha(t)) + \int_0^t g(y(\tau),\alpha(\tau))d\tau \right\}.$$

The control set are L^∞ function, h and g are data and the trajectory $y(\cdot)$ is given by an ordinary differential equation.
Obtaining the optimal cost function, defined by $u(x) = \inf_{\alpha\in\mathcal{A}} J(x,\alpha)$, is not easy in general. We approximate $u(x)$ as the supremum over $t > 0$ of the following evolution problems:

$$u(t,x) = \inf_{\alpha} \operatorname{ess\,sup}_{s\in[0,t)} \left\{ h(y(s),\alpha(s)) + \int_0^s g(y(\tau),\alpha(\tau))d\tau \right\}.$$

For these evolution problems we present the associated Hamilton-Jacobi-Bellman equation. As this HJB equation is consistent with a numerical procedure, we use this discretization to obtain a procedure for the primitive problem.
For the numerical solution of the ergodic version of this problem we will also need a perturbation of the instantaneous cost function. We give an appropriate selection of the discretization and penalization parameters to obtain discrete solutions that converge to the optimal cost.
We present numerical results made upon two examples.

On freezing of a finite humid porous medium with a heat-flux condition. **Eduardo Santillan Marcus** (Universidad Austral de Rosario, Argentina) IC/MT590/015

Let us consider the flow of heat and moisture through a finite porous half-space during freezing. The position of phase change front at time t, given by $x = s(t)$,divides the porous body into two regions. Let us denote by $u = u(x,t), v = v(x,t)$, and $w = w(x,t)$ the temperature distribution in the freezing region and the temperature distribution and the moisture distribution in the region where coupled heat and moisture flows respectively. In $0 < x < s(t)$ there is no moisture movement, and in $s(t) < x < 1$ the process of the coupled heat and moisture flows is described by the well known Luikov's system. Equivalence between this problem and a system of Volterra integral equations is found. The existence of a unique local solution in time for this problem is also obtained.

Littlewood–Paley spline wavelets: a simple and efficient tool for signal and image processing in industrial applications. **Eduardo Serrano** (Universidad Nacional de San Martín, Argentina), Maria Figliola (Fibertel, Argentina) IC/MT693/015

Wavelets play a significant role in applied mathematics when time-scale methods are required, or it performs better than Fourier methods. When the shift-invariance is needed or large scales phenomena are as important as small scales ones, the correct tool for analyzing is the Continuous Wavelet Transform.
This transform is not correlated with orthonormal wavelet bases or a multiresolution scheme. Otherwise, it gives us a continuous spectra of filtered versions of the signal resulting from its convolutions with the analyzing wavelet, well localized both in time and the frequency domain. However, a non trivial problem is to choice the analyzing wavelet, to compute the continuous transform from the sampled or experimental data and to deal with the numerical results.

Here we propose a simple option. We will call Littlewood–Paley wavelet, any one defined from the difference $\psi(t) = 2\varphi(2t) - \varphi(t)$, where $\varphi(t)$ is an appropriate basic function acting as low-pass filter. Then,the wavelet acts as a band-pass filter, having some null moments. We design the basic function in the cubic spline class. In this way, we get the numerical advantages of the spline framework. Simple and efficient algorithms can be developed.

Existence and multiplicity of solutions for elliptic problems arising in plasma physics with indefinite discontinuous nonlinearities. **Marco Calahorrano** (Escuela Politécnica Nacional, Ecuador) IC/MT786/015

In this paper we study the critical points for a locally Lipschitz functional that in some sense will be solutions of the elliptic problem with indefinite discontinuous nonlinearities. We should mention that our results were inspired by the work of Ambrosetti–Badiale, Arcoya–Calahorrano and Chang. For the problem studied in Ambrosetti,A., Badiale, M.(The dual variational principle and elliptic problems with discontinuous nonlinearities, *J. Math. Anal. Appl.*, **140** (1989), 363–373.), we introduce the indefinite nonlinearities as in Alama, S., Tarantello, G. (On semilinear elliptic equations with indefinite nonlinearities) and Berestycki, H., Capuzzo-Dolcetta, I., Nirenberg, L., (Variational methods for indefinite superlinear homogeneous elliptic problems, *NoDEA*, **2** (1995), 553–572) and we obtain the existence and multiplicity of solutions using the critical points theory developed by Chang in Variational methods for nondifferentiable functionals and their applications to partial differential equations, *J. Math. Anal. Appl.*, **80** (1981), 102–129.
Applications for Plasma Physics are considered with nonlinearities that change sign.

IC/MP260/015: Applied mathematics in Latin America: part 1. #2

Well-posedness, stability and numerical results for the thermoelastic behavior of a coupled joint-beam PDE–ODE system modelling the transverse motions of the antennas of a space structure. **Ruben Spies** (IMAL (CONICET -UNL), Argentina), Eugene Cliff (Interdisciplinary Center for Applied Mathematics„ USA), Zhuangyi Liu (University of Minnesota, USA), Terry Herdman (Virginia Tech., USA) IC/MT798/015

A mathematical model for both axial and transverse motions of two beams with cylindrical cross-sections coupled through a joint is presented and analyzed. The motivation for this problem comes from the need to accurately model damping and joint dynamics for the next generation of inflatable/rigidizable space structures. Thermo-elastic damping is included in the two beams and the motions are coupled through a joint which includes an internal moment. Thermal response in each beam is modeled by two temperature fields. The first field describes the circumferentially averaged temperature along the beam, and is linked to the axial deformation of the beam. The second describes the circumferential variation and is coupled to transverse bending. The resulting equations of motion consist of four, second-order in time, partial differential equations, four, first-order in time, partial differential equations, four second order ordinary differential equations, and certain compatibility boundary conditions. The system is written as an abstract differential equation in an appropriate Hilbert space, consisting of function spaces describing the distributed beam deflections, and temperature fields, and a finite-dimensional space that projects important features at the joint boundary. Semigroup theory is used to prove the system is well-posed, and that with positive damping parameters the resulting semigroup is exponentially stable. Steady states are characterized and several numerical approximation results are presented.

Recent developments on the Boltzmann equation and its applications. **Liliane Barichello** (Universidade Federal do Rio Grande do Sul, Brazil) IC/MT656/015

In recent years, an increased interest in the general area of rarefied gas dynamics has been noted, essentially because of some applications related to micro-machines and microeletro-mechanical systems. However, research in this area is also related to aerospace applications and environmental problems, in particular, aerosol mechanics. This field is associated with the kinetic theory of gases as described by the integro-differential equation proposed by Boltzmann in 1872. A linear version of the Boltzmann equation is also a main tool in the treatment of radiative transfer problems (including bio-medical applications), neutron transport problems and the study of the behavior of electrons in semiconductors.

In this work we present recent results obtained from spectral methods, in deriving solutions for kinetic models of the Boltzmann equation. In particular, a wide class of solutions developed, for classical problems in the rarefied gas dynamics, by an analytical version of the discrete-ordinates method is discussed.

Eigenanalysis of multi-walled carbon nano-tubes by using the impulse response. **Julio Claeyssen** (Universidade Federal do Rio Grande do Sul, Brazil), Rosemaira Copetti (Universidade Federal de Santa Maria, Brazil), Teresa Tsukazan (Universidade Federal do Rio Grande do Sul, Brazil), Sandra Vielmo (Universidade Federal de Santa Maria, Brazil) IC/MT1492/015

We shall consider multi-walled carbon nanotubes (MWNT) modelled as an assemblage of Euler-Bernoulli or Timoshenko beams connected throughout their length by springs subject to van der Waals interaction between any two adjacent nanotubes. The intertube displacements modes correspond to noncoaxial intertube resonances. The beams are subject to arbitrary boundary conditions and damping. This later includes Kelvin-Voigt internal damping and external viscous damping. For determining frequencies and modes, we study a second-order evolution system on which the stiffness matrix depends upon the eigenvalue. For this we shall employ an approach in the physical domain that is based upon a fundamental matrix response. The basis generated by this response allows to simplify the boundary problem for determining the modes. This eigenanalysis will allow to study forced responses of MWNT under classical and non-classical boundary conditions. This approach can be useful in approximating real situations with sufficiently accuracy. The transient behavior of forced responses can be explicitly identified in terms of the impulse response.

Exact solution for a Stefan problem with convective boundary condition and density jump. **Domingo Tarzia** (CONICET - Univ. Austral, Rosario - ARGENTINA) IC/MT867/015

We consider the solidification of a semi-infinite material which is initially at its liquid phase at a uniform temperature T_i. Suddenly at time $t > 0$ the fixed face $x = 0$ is submitted to a convective cooling condition with a time-dependent heat transfer coefficient of the type $H(t) = ht^{-1/2}$ $(h > 0)$. The bulk temperature of the liquid at a large distance from the solid-liquid interface is T_∞, a constant temperature such that $T_\infty < T_f < T_i$ where T_f is the freezing temperature. We also consider the density jump between the two phases. We obtain that the corresponding phase-change (solidification) process has an explicit solution of a similarity type for the temperature of both phases and the solid-liquid interface, if and only if the coefficient h is large enough, that is $h > h_0 = \frac{k_l}{\sqrt{\pi \alpha_l}} \frac{T_i - T_f}{T_i - T_\infty}$ where k_l and α_l are the conductivity and diffusion coefficients of the initial liquid phase. Moreover, when $h \leq h_0$ we only have a heat conduction problem for the initial liquid phase and the corresponding change of phase does not occur.

IC/MP264/040: Recent advances in the analysis of nonlinear parabolic equations and their singular limits.

Organiser: Cyrill Muratov (New Jersey Institute of Technology, USA)
Co-organiser: Peter Gordon (New Jersey Institute of Technology, USA)

This minisymposium is devoted to recent advances in the analysis of reaction–diffusion and related problems which naturally arise in numerous applications such as combustion, phase transitions, and biological modeling. The focus of the talks will be on recent rigorous results on formation and global in time evolution of coherent structures. The first half of the talks will address problems of front propagation and failure in homogeneous and inhomogeneous media in the presence of advection. The second half will discuss a number of singular limits leading to the formation and non-trivial dynamics of topological defects, such as point defects, filaments and sharp reaction fronts. The analysis relies heavily on the tools of functional analysis, calculus of variations, maximum principle, and degree theory.

A variational approach to front propagation in infinite cylinders. **Cyrill Muratov** (New Jersey Institute of Technology, USA) IC/MT1071/040

In their classical 1937 paper, Kolmogorov, Petrovsky and Piskunov proved that for a particular class of reaction-diffusion equations on the line the solution of the initial value problem with the initial data in the form of a unit step propagates at long times with constant velocity equal to that of a certain special traveling wave solution. This type of a propagation result has since been established for a number of general classes of reaction-diffusion-advection problems in cylinders. In this talk I will show that actually in the problems without advection or in the presence of transverse advection by a potential flow these

results do not rely on the specifics of the problem. Instead, they are a consequence of the fact that the considered equation is a gradient flow in an exponentially weighted L^2-space generated by a certain functional, when the dynamics is considered in the reference frame moving with constant velocity along the cylinder axis. Independently of the details of the problem only three propagation scenarios are possible in the above context: no propagation, a "pulled" front, or a "pushed" front. The choice of the scenario is completely characterized via a minimization problem.

Boundary layers and KPP fronts in a cellular flow. **Alexei Novikov** (Penn State University, USA) IC/MT1074/040

The objective of this talk is to describe how fluid cellular flows with large intensity affect front propagation. We consider propagation of premixed flames with unit Lewis number in incompressible flows with asymptotically large intensity. The speed-up of flame-fronts and their structure will be determined. This work is done with L. Ryzhik.

Traveling waves in a 2D cylinder with undulating boundary and their homogenization limit. **Ken-Ichi Nakamura** (University of Electro-Communications, Japan) IC/MT2062/040

We discuss traveling waves for a curvature-driven motion of plane curves in a two-dimensional cylinder Ω with periodically undulating boundary. The law of motion of the curve is given by

$$V = \kappa + A,$$

where V denotes the normal velocity of the curve, κ denotes the curvature and A is a positive constant representing a constant driving force. This equation appears as a certain singular limit of an Allen-Cahn type nonlinear diffusion equation and the solution curve represents the interface between two different phases.

We study how the average speed of the periodic traveling wave depends on the geometry of the domain boundary $\partial\Omega$. More specifically, we consider the homogenization problem as the period of the boundary undulation, denoted by ε, tends to zero, and determine the homogenization limit of the average speed of periodic traveling waves. Quite surprisingly, this homogenized speed depends only on the maximum opening angle of the domain boundary and no other geometrical features are relevant. Our analysis also shows that, for any small $\varepsilon > 0$, the average speed of the traveling wave is smaller than A, the speed of the planar front. This implies that boundary undulation always lowers the speed of traveling waves, at least when the bumps are small enough.

This presentation is based on a joint work with Bendong Lou (Tongji University, China) and Hiroshi Matano (University of Tokyo, Japan).

Vortex and filament dynamics in Ginzburg–Landau theories. **Giandomenico Orlandi** (Università degli Studi di Verona, Italy) IC/MT1122/040

In a series of papers with F. Bethuel and D. Smets (Paris VI), we prove that, for the complex parabolic Ginzburg–Landau equation, asymptotically, vorticity evolves according to motion by mean curvature in Brakke's weak formulation. In the two dimensional case we prove that, in a suitable time scaling, vortices evolve according to a simple ordinary differential equation, which is a gradient flow of the Kirchhoff-Onsager functional. This convergence holds except for a finite number of times, corresponding to vortex collisions and splittings, which we describe carefully. The only assumption is a natural energy bound on the initial data.

A variational free-boundary problem arising in combustion theory. **Matteo Novaga** (Università di Pisa, Italy) IC/MT769/040

I will describe a variational approach applied to a singular limit of reaction–diffusion–advection equations which arise in combustion modeling. This approach allows to establish existence, uniqueness, monotonicity, asymptotic decay, and the associated free boundary problem for special traveling wave solutions which are minimizers of the considered variational problem. These minimizers are also demonstrated to be the limts of the minimizers of the corresponding approximating problems. I will also discuss matching upper and lower bounds for the speed of the minimizers in the singular limit, in terms of an area-type functional for small curvatures of the free boundary, leading to a rigorous justification of the Markstein model of flame motion.

On the κ–θ model of cellular flames: asymptotics and numerical simulations. **Claude-Michel Brauner** (Université de Bordeaux, France) IC/MT1620/040

Premixed gas combustion represents a rather intricate physical system involving fluid dynamics, multistep chemical kinetics, as well as molecular and radiative heat transfer. Its essential dynamical feature is formation of the so-called flame sheet propagating in a travelling wave type fashion. The basic propagation mode exhibits two main mechanisms of destabilization: one due to the thermal expansion of the gas known as the hydrodynamic instability, and the thermal-diffusive instability which is a result of the competition between the exothermic reaction and the heat diffusion. The thermal-diffusive instability manifests itself by generating a cellular structure, which in turn exhibits a chaotic dynamics. However, the cellular instability may be successfully captured by a simpler system comprised of only two equations. We consider the $\kappa - \theta$ model of flame front dynamics introduced by Frankel, Gordon and Sivashinsky. Its weakly nonlinear version reads:

$$\Phi_t + \frac{1}{2}\Phi_x^2 = \Phi_{xx} - \Theta, \tag{1}$$

$$\Theta_t + \Phi_x\Theta_x = \Theta_{xx} + \alpha\Phi_{xx} - \Theta. \tag{2}$$

Near the instability threshold ($\alpha = 1$), the front is arbitrarily close to the solution of the Kuramoto–Sivashinsky equation on a fixed time interval if the evolution starts from close configurations. We present numerical simulations that illustrate the theoretical results and also demonstrate the ability of the $\kappa - \theta$ to generate chaotic cellular dynamics.

This is joint work with M. Frankel, J. Hulshof, A. Lunardi, G.I. Sivashinsky and V. Roytburd.

Quenching, propagation and blow up in porous media combustion. **Peter Gordon** (New Jersey Institute of Technology, USA) IC/MT1073/040

Gaseous detonation is a phenomenon with very complicated dynamics which has been studied extensively by physicists, mathematicians and engineers for many years. Despite many efforts the problem is far from complete resolution. Recently Sivshinsky and his collaborators proposed the theory of subsonic detonation that occurs in hydraulically resistant porous media. This theory provides a model which is realistic, rich and suitable for a mathematical study. In particular, the model is capable of describing the transition from a slowly propagating deflagration wave to the fast detonation wave. This phenomena is known as a deflagration to detonation transition and is one of the most challenging issues in combustion theory. I will present some recent mathematical results concerning traveling front solutions arising in the context of the model. In particular, it will be shown that under very general assumptions the model admits traveling wave solutions. Moreover, these solutions unique in a presence of small but finite thermal diffusivity. This result strongly suggests that transition from deflagration to detonation is unavoidable unless quenching occurs. Some results on quenching, propagation limits of the combustion fronts and initiation of detonation in porous media will also be discussed. In particular, it will be shown that initiation of detonation can be formulated as a blow up problem.

Heat flows for director fields: the evolution of singularities. **Michiel Bertsch** (Consiglio Nazionale delle Ricerche, Italy) IC/MT1410/040

We discuss the evolution of director fields from domains in $\mathbb{R}^2$ or $\mathbb{R}^3$ to the unit sphere S^2. The simplest possible heat flow is described by the nonlinear parabolic system $u_t = \Delta u + |\nabla u|^2 u$, where the right hand side is generated by the Euler–Lagrange equation corresponding to the energy functional $\frac{1}{2}\int |\nabla u|^2 dx$. More complicated versions of this equation may contain additional terms which are important for the global dynamics of solutions, and they arise in the theories of liquid crystals or micromagnetism.

It is known that even in the case of smooth data classical solutions do not always exist globally; i.e., for all times. Singularities may occur in finite time, but it turns out that their evolution is not always uniquely determined by the data. In the talk we give an overview of recent results and present a list of open problems.

IC/MP149/040: Numerical verification methods for solutions of partial differential equations.

Organiser: Mitsuhiro Nakao (Kyushu University, Japan)
Co-organiser: Michael Plum (Universität Karlsruhe, Germany)

It is a purpose of this minisymposium to give a state of the art for the numerical approaches to the proof of the existence of solutions for partial differential equations(PDEs). Four speakers have been devoted for years to concerning research related to PDEs. Several kinds of leading principles of the verification methods will be presented by showing interesting and important numerial examples in applied analysis. These results would confirm us the actual effectiveness of the computer assisted proofs in the theory of nonlinear PDEs as well as suggest the methods to get useful *a posteriori* error estimates in mathematically rigorous sense for the numerical solutions of PDEs.

Computer assisted proofs for Navier–Stokes problems. **Mitsuhiro Nakao** (Kyushu University, Japan) IC/MT554/040

In this talk, we first give an overview of our numerical methods to verify, in mathematically rigorous sense, the existence of solutions for nonlinear elliptic boundary value problems. Our approach is based on the combination of fixed point theorems in functional spaces and the constructive error estimates of finite element (or spectral) method. Then, we describe on the way to apply the method to enclose the solution of the stationary Navier-Stokes equations with driven cavity flow in two dimension.

Our main topic in this talk consists of the clarlifying the global bifurcation structures in the heat convection problems known as Rayleigh-Bénard problem governing by the Navier-Stokes equation with nonlinear heat conduction. There are no longer any methods up to now in the existing theoretical approaches for such a complicated problems. Therefore, we considered a computer assisted approach to prove the existence of bifurcating solutions for the concerning problem.

First, under stress free boundary condistions on velocity, we derived several kinds of verified solutions for various Prandtl and Rayleigh numbers as well as to prove the existence of a symmetry breaking bifurcation point in two dimension. Second, we extend our results to three dimensional cases to be more difficult but more realistic and interesting bifurcation phenomena in the fluid mechanics. Overcoming various kind of difficulties of verification procedure compared with two dimensional case, several kinds of interesting solutions are verified, i.e., hexagonal, retangular, roll and mixed types, which will be shown in the presentation. Furthermore, we consider other boundary conditions by using different kind of base functions, e.g., Chebyshev series.

We believe that these methodologies and results should be actually significant and important from the viewpoint of the rigorous mathematical analysis on computer.

Numerical enclosures for photonic band gaps, I. **Michael Plum** (Universität Karlsruhe, Germany), Christian Wieners (Universität Karlsruhe (TH), Germany), Vu Hoang (Universität Karlsruhe (TH), Germany) IC/MT1017/040

We consider the propagation of optical waves in a periodic medium (*photonic crystal*), a problem which is mathematically described by the (homogeneous) Maxwell equations on the whole of $\mathbf{R}^n$, with periodic permittivity and permeability. The investigation of monochromatic waves leads to a spectral problem for the Maxwell operator. It is well known that the spectrum is characterized as a countable union of compact real intervals ("bands") $\Lambda_j = \{\lambda_j(\mathbf{k}) : \mathbf{k} \in \mathcal{B}\}$, with $\lambda_j(\mathbf{k})$ denoting the j-th eigenvalue of a Maxwell eigenvalue problem in the fundamental domain of periodicity, with quasi-periodic boundary conditions depending on a parameter $\mathbf{k}$ varying within the Brillouin zone $\mathcal{B}$, which is a known compact set in $\mathbf{R}^n$. Depending on the periodic material distribution, band gaps can occur, and in practical applications it is important to know (but analytically difficult to decide) if this really happens.

In this and the next talk by C. Wieners, we will attack this problem by computer-assisted means. In this talk, we present a method for reducing the task of computing $\lambda_j(\mathbf{k})$ for *all* $\mathbf{k} \in \mathcal{B}$ to *finitely many grid points* in $\mathcal{B}$. This is done by a perturbation argument based on *a priori* estimates for differences of Maxwell operators (with slightly different $\mathbf{k}$ values) and resolvent estimates, which result in enclosures for $\lambda_j(\mathbf{k})$ with $\mathbf{k}$ *between* the grid points in terms of enclosures for $\lambda_j(\mathbf{k})$ with $\mathbf{k}$ *in* the grid, which can be attacked numerically, as explained in the next talk by C. Wieners.

Numerical enclosures for photonic band gaps, II. **Christian Wieners** (Universität Karlsruhe (TH), Germany), Michael Plum (Universität Karlsruhe, Germany) IC/MT1016/040

As described in the previous talk by M. Plum, the problem of enclosing the spectral bands, and thus, of proving the occurrence of spectral gaps for photonic crystals (i.e., for Maxwell operators with periodic permittivity and permeability), can be reduced to enclosing the eigenvalues $\lambda_j(\mathbf{k})$ of the Maxwell operator on the fundamental domain of periodicity for *finitely many grid points* $\mathbf{k}$ in the Brillouin zone $\mathcal{B}$, and for finitely many j.
Here, we present a numerical method for the guaranteed enclosure of these eigenvalues. For this purpose, sufficiently close explicit eigenvalue bounds (based on techniques due to Weinstein, Kato, Rayleigh-Ritz, and Lehmann-Goerisch) are required. This has to be combined with a suitable sequence of comparison problems in order to provide additionally required information on the rest of the spectrum. Together with the perturbation method described in the previous talk, this numerical eigenvalue enclosure method can be used for rigorously proving the existence of band gaps for a given periodic material. Moreover, the method computes the band gap width within guaranteed bounds.

Finally, we present a numerical example for a 2-d periodic configuration, where we are able to prove the existence of a spectral gap; in this situation, no analytical approach to proving this is known. For this purpose, we use higher order finite element approximations, a Ritz-Galerkin eigenvalue solver, a parallel linear multigrid preconditioner, verified integration techniques, and interval arithmetic to control rounding errors.

A theorem for numerical verification of local uniqueness . **Nobito Yamamoto** (The University of Electro-Communications, Japan) IC/MT1415/040

Numerical verification methods, so called Nakao's methods, have been developed for computer-assisted proofs of existence of solutions to PDEs. The methods give guaranteed error bounds for calculated approximate solutions through error analysis of the approximation and fixed-point theorems.

PDEs are transformed into residual equations and transformed again into fixed-point equations. Then, for example, Schauder's fixed-point theorem is applied to prove the existence of the solutions. The conditions of the fixed-point theorem are modified through the error analysis and tried to verify using numerical techniques with computers.

In order to show the local uniqueness of the solution, we have applied a modified version of Banach's fixed-point theorem[1]. The version is intricately described in order to fit it to apply to Nakao's methods. In the present talk, we propose a generalized version of the previous work, which is simplified in the description from mathematical point of view and can be applied to more general problems.

The fixed-point equations are supposed to have Fréchet differentiable operators. Our theorem gives conditions in order that a given set of functions includes a unique solution to the fixed-point equation. Moreover, we show a lemma which concerns the mean value form for operators on function spaces which needs more additional conditions than the mean value form for functions on complex field. Numerical examples will be shown in order to explain how to apply our theorem.

[1] Yamamoto, N.; A numerical verification method for solutions of boundary value problems with local uniqueness by Banach's fixed point theorem. SIAM Journal on Numerical Analysis, Vol.35, No.5, (1998), pp.2004–2013.

IC/MP167/040: Dynamics of nonlinear waves in heterogeneous media.

Organiser: Yasumasa Nishiura (Hokkaido University, Japan)
Co-organiser: Jack Xin (University of California, Irvine, USA)

Nonlinear waves, such as kinks (fronts), pulses and spots, interact in various ways with inhomogeneous external environments. A representative case comes from the heterogeneity of the media that is generic in physics, chemistry, and biology. It may be a simple discontinuity, periodic or random media depending on the underlying phenomena. A wide variety of outputs have been observed after the interactions between those traveling waves and heterogeneous media such as penetration, repulsion, annihilation, splitting, propagation failures, and even more exotic behaviors including spatio-temporal chaos. At the same time many mathematical ideas have been extracted through the analysis of the above dynamics such as asymptotic averaging, effective properties, and reduction methods to ODEs. In this minisymposium, we bring together researchers who study these phenomena from numerical, analytical and experimental points of view, and show how they are interwoven in a unified way and make this field interesting. We also explore mathematical methods that are potentially applicable to a broad range of problems in this area.

Heterogenitiy-induced pulse dynamics in dissipative systems. **Yasumasa Nishiura** (Hokkaido University, Japan), Kei-Ichi Ueda (Kyoto University, Japan), Takashi Teramoto (Chitose Institute of Science and Technology, Japan) IC/MT2817/040

Particle-like (spatially localized) dissipative patterns arise in many fields such as chemical reaction, gas-discharge system, liquid crystal, binary convection, and morphogenesis. We discuss about the dynamics of moving particles in heterogeneous media, especially for the three types of heterogeneities: jump, bump, and periodic media respectively. Model systems include the Gray-Soctt model and a three-component reaction diffusion system of one-activator-two-inhibitor type. We focus on the following issues:(a) heterogeneity-induced defect-structure created around the jump point, (b) collision dynamics between particles and defects, (c) unstable objects called scattors which sort out the destinations of orbits, and (d) an organizing center creating traveling pulses, defects, and scattors via unfolding. When traveling objects like pulses or spots encounter heterogeneities, a variety of outputs are produced such as annihilation, rebound, splitting, and relaxing to an ordered pattern. It turns out that there is a class of unstable patterns called scattors which play a role of separator whose unstable manifolds guide the orbits to their destinations. For 1D case, a unified view is presented by a global solution branch with respect to the parameters chracterizing the heterogeneities that contain all the above important objects including traveling pulses, defects, and scattors.

Cell behaviors in heterogeneous media in an amoeba. **Toshiyuki Nakagaki** (Hokkaido University, Japan), Seiji Takagi (Hokkaido University, Japan), Ryo Kobayashi (Hiroshima University, Japan), Tero Atsushi (Hokkaido University, Japan), Tetsu Saigusa (Hokkaido University, Japan), Kei-Ichi Ueda (Kyoto University, Japan), Yasumasa Nishiura (Hokkaido University, Japan) IC/MT1810/040

The plasmodium of *Physarum polycephalum* in primitive creature of true slime mold is a large amoeboid organism, known as a good experimental model for studying physiology and dynamics of cell behaviors. Intracellular nonlinear waves and oscillations of biological activity have been reported in relation to cell behaviors and have been analyzed by nonlinear dynamics. In this talk, we will focus on effects of heterogeneous environment on cell behavior: indecisive behavior in crossing environmental barrier, and morphogenesis of cell shape under heterogeneous illumination of toxic light, etc. A simple mathematical

model for observed behavior is proposed in terms of dynamical system with a spatially heterogeneous parameter. Discussion is made on physiological significance of model dynamics.

Tango waves in inhomogeneous calcium excitable media. **Yuexian Li** (University of British Colombia, Canada) IC/MT3519/040

Oscillations and travelling waves are often observed in intracellular levels of calcium (Ca^{2+}) when egg cells are either activated by a sperm or by other kinds of stimuli. This is often due to the existence of Ca^{2+} stores that are capable of dynamically releasing Ca^{2+}, making the intracellular medium a Ca^{2+} excitable medium (Li et al, Am J Physiol 296:C1079, 1995). Tango waves are wave fronts that propagate in a back-and-forth manner and was found in a bidomain model of Ca^{2+} waves in frog eggs (Li, Physica D, 186:27, 2003). We show that such waves can occur in the presence of a time-dependent spatial inhomogeneity in an excitable medium. Analysis of such a phenomenon was carried out using the FitzHugh-Nagumo (FN) model with a spatially varying but time-independent term, $z(x)$, added to the first equation. Inhomogeneities cause pinning and oscillations of the front. This is best shown when $z(x)$ is a linear ramp. When the slope is large, it stabilizes the front. The front becomes less stable as the slope decreases. At a critical slope, the front becomes unstable through a Hopf bifurcation beyond which oscillations occur (Prat & Li, Physica D, 186:50, 2003). These results were generalized to a wider class of excitable media including systems of PDEs and IDEs (integral-differential equations) (Prat et al, Physica D, 202:177, 2005). In this talk, I will present a summary of these results.

Dynamics of localized patterns in heterogeneous media. **Kei-Ichi Ueda** (Kyoto University, Japan), Takashi Teramoto (Chitose Institute of Science and Technology, Japan), Xiaohui Yuan (Hokkaido University, PR China), Yasumasa Nishiura (Hokkaido University, Japan) IC/MT2050/040

We study pulse dynamics in one-dimensional heterogeneous media of bump type, namely one parameter of the system undergoes an abrupt change. Depending on the height of the bump, the responses of pulse behavior are penetration, rebound and splitting. Taking paramters close to singularities of codim 2 type consisting of drift and saddle-node instabilities, the PDE dynamics can be reduced to a finite-dimensional system which displays the three outputs. Moreover we show that steady solutions and their stable and unstable manifolds direct the flow of orbits.

Variational principles and reaction–diffusion front speeds in random flows. **Jack Xin** (University of California, Irvine, USA) IC/MT2779/040

An overview is presented on recent progress in analyzing reaction-diffusion front speeds in random flows with Gaussian statistics based on variational principles. Probabilistic tools such as path integral representations, properties of Gaussian processes (Borel inequality, growth law of running extrema), and large deviation methods are brought to action in concert with classical methods (comparison principle, multi-scale test functions). The front speeds depend on both the intensity and covariance of the random flows. Variational principle also allows efficient computation of speed statistics in lieu of direct simulations. Specific examples are front speeds in random shear flows, and randomly perturbed cell flows.

Homogenization for first- and second-order fully-nonlinear PDF in stationary ergodic media. **Panagiotis Souganidis** (University of Texas at Austin, USA) IC/MT3796/040

In this talk I will review recent developments in the theory of homogenization of fully nonlinear first- and second-order partial differential equations in random (stationary, ergodic) environments.

Speed-up of reaction-diffusion fronts by strong flows. **Andrej Zlatoš** (University of Chicago, USA) IC/MT2052/040

We present recent results on speed-up of traveling fronts by strong flows in reaction-diffusion equations. We characterize periodic flows which can arbitrarily speed up fronts for general combustion-type reactions in two dimensions, as well as those which achieve the fastest speed-up rates for KPP reactions in any dimension. Relations to quenching of reactions and to homogenization in the associated passive scalar equations will also be discussed.

Long-time dynamics to non-linear particle interacting systems of Maxwell type. **Irene Gamba** (University of Texas at Austin, USA) IC/MT3674/040

We study long time dynamics to solutions of initial value problems to a rather general multi-linear Boltzmann kinetic models of Maxwell type interactions that may describe qualitatively different processes in applications, but have many features in common. In particular we focus in the existence, uniqueness and asymptotics to dynamical scaling (self-similar) solutions and connections to Central Limit theorems for non-Gaussian states.

We use a relationship of spectral properties of the problem in Fourier space to study qualitative properties of the solution of the original initial value problem as well as the characterization of the domain of attraction to self-similar states. We clarify the connection with contractive measures for the pdf solution of the kinetic problem and discuss the optimal decay rates.

Examples are models of Maxwell type in classical space homogeneous, elastic or inelastic Boltzmann equation, and the elastic Boltzmann equation in the presence of a thermostat, all with finite or infinite initial energy, as well as Pareto distributions models in economy or more general Multiplicatively Interacting Stochastic Processes

This is in part a collaborative work with A. Bobylev and C. Cercignani.

IC/MP158/040: Nonlinear parabolic equations and their applications.

Organiser: Gieri Simonett (Vanderbilt University, USA)
Co-organiser: Patrick Guidotti (UC Irvine, USA)

This minisymposium features talks about theoretical aspects of nonlinear parabolic equations as well as their applications to Physics, Biology and Fluid Dynamics.

Global well-posedness for a model of haptotaxis. **Christoph Walker** (Vanderbilt University, USA), Glenn Webb (Vanderbilt University, USA) IC/MT1600/040

A system of non-linear partial differential equations modeling tumor invasion into surrounding healthy tissue is analyzed. The model incorporates haptotaxis, i.e., the directed migratory respond of tumor cells to the extracellular environment, as well as spatial and age structure of the tumor cells. Global existence and uniqueness of non-negative solutions is shown.

Asymptotic behaviour of some nonlocal problems. **Michel Chipot** (Universität Zürich, Switzerland) IC/MT1930/040

We investigate the asymptotic behaviour of nonlinear nonlocal equations and systems of parabolic type.

Large-time behavior of solutions of superlinear parabolic equations. **Peter Poláčik** (University of Minnesota, USA) IC/MT3399/040

We shall discuss several results on the large time behavior of solutions of nonlinear parabolic equations derived by means of parabolic Liouville theorems.

IC/MP158/040: Nonlinear parabolic equations and their applications. #2

Organiser: Gieri Simonett (Vanderbilt University, USA)

(For abstract, see session #1 above.)

Parabolic equations on singular manifolds. **Herbert Amann** (Universität Zürich, Switzerland) IC/MT1469/040

We will report on new results concerning the solvability of parabolic equations on manifolds with cusps, corners, and edges.

Maximal regularity for degenerate evolution equations with an exponential weight function. **Gieri Simonett** (Vanderbilt University, USA) IC/MT2957/040

In this talk we consider a class of degenerate evolution equations on the real line that have the distinguished feature that they contain an exponential weight function in front of the time derivative. Our interest is motivated by problems that arise from elliptic or parabolic equations on angles and wedges, and by free boundary problems with moving contact lines.

A modification of the Perona–Malik equation. **Patrick Guidotti** (UC Irvine, USA) IC/MT2532/040

A modification of the classical Perona–Malik equation of image processing is proposed which exhibits improved features at the analytical and at the practical level. The Perona–Malik is well-known to be ill-posed. The proposed modification has the advantage of being well-posed without introducing regularization terms which are known to lead to undesired blurring. The modification admits classical solutions and characteristic functions are stationary solutions; it also allows for a simple and effective discretization. Both analytical results and numerical experiments will be presented.

IC/MP50/015: Qualitative properties of nonlinear hyperbolic equations.

Organiser: Messaoudi Salim (King Fahd University, Saudi Arabia)
Co-organiser: Mokhtar Kirane (Université de La Rochelle, France)

We focus on qualitative studies of nonlinear hyperbolic equations and systems arising in various fields of applied sciences such as aeroelasticity, plasma physics, visoelasticity, geophysics and biology. Our aim is to bring together new ideas and methods for better understanding of many phenomena.

Our topics include: global existence, asymptotic behavior, finite time blow-up, transient profiles, and control.

Hyperbolic systems driven by controls taking values from the space of vector measures. **Nasiruddin Ahmed** (Université d'Ottawa, Canada) IC/MT691/0

Let I be a closed bounded interval, E, F separable Banach spaces and Σ the sigma algebra of subsets of the set I. The general system model considered in this paper is given by

$$dx = Axdt + B(dt)x + f(t,x)dt + g(t,x)\nu(dt), x = x_0, t \in I$$

where A is the infinitesimal generator of a C_0 semigroup on the Banach space E and B is an operator valued measure mapping Σ to $\mathcal{L}(E)$, the space of bounded linear operators on E, f is a nonlinear map from $I \times E$ to E and $g : I \times E \longrightarrow \mathcal{L}(F,E)$ and ν is any countably additive bounded F valued vector measure defined on Σ. We consider several control problems with objective (cost) functionals of the form

$$J(B) \equiv \int_I \ell(t,x)dt + \Psi(x(T)) + \varphi(\overline{B}) \longrightarrow \inf$$

where $\overline{B}$ denotes the total variation of the operator valued measure B. The infimum is taken over an admissible set $\mathcal{V}_{ad} \subset \mathcal{M}_{cabv}(\Sigma, \mathcal{L}(E))$, the space of countably additive bounded vector measures having bounded variations.

We present several results on existence of optimal policies under different assumptions and properties of the admissible set $\mathcal{V}_{ad}$. The abstract results are applied to structural control problems arising in theoretical mechanics, and hyperbolic and parabolic systems with coefficients containing measures.

Necessary conditions of optimality for such problems can be found in Ref 1.

Qualitative properties of a nonlilear wave equation. **Jorge Esquivel-Avila** (Universidad Autonoma Metropolitana, Mexico) IC/MT873/0

We consider a nonlinear wave equation without damping and with a superlinear source term. We analyze the qualitative behavior of solutions forwards and backwards for any value of initial energy. We present characterizations of blow-up, boundedness and convergence to the set of nonzero equilibria as $t \to \pm\infty$. In particular, we present the dynamics around the ground state in case that initial energy is equal to the mountain pass value. Usually, boundedness of global solutions is shown when the source term satisfies a condition on the superlineality. We avoid such restriction. We also consider initial energy bigger than the mountain pass value.

Solvability and regularity of a semi-linear hyperbolic equation with Neumann boundary control. **Andrzej Nowakowski** (University of Lodz, Poland) IC/MT795/0

The paper is devoted to study existence and stability of weak solutions for the following hyperbolic equations with controls in Neumann boundary conditions:

$$\begin{aligned} &x_{tt}(t,z) - \Delta_z x(t,z) = f(t,z,x(t,z)) \quad \text{a.e. on } (0,T)\times\Omega \\ &x(0,z) = \phi(0,z), \quad x_t(0,z) = \psi(0,z) \text{ on } \Omega \\ &\partial_\nu x(t,z) = v(t,z) \text{ on } (0,T)\times\Gamma, \quad v(t,z) \in \mathbf{V} \text{ on } (0,T)\times\Gamma, \end{aligned}$$

where Ω is a given bounded domain of $\mathbb{R}^n$ with boundary $\Gamma = \partial\Omega$ of C^2, $\Sigma = (0,T)\times\Gamma$, $\mathbf{V}$ is a given nonempty, closed set in R, $f : [0,T]\times\bar{\Omega}\times\mathbb{R} \to \mathbb{R}$, and $\varphi, \psi : \mathbb{R}^{n+1} \to \mathbb{R}$ are given functions, $\varphi(0,\cdot) \in H^1(\Omega)$, $\psi(0,\cdot) \in L^2(\Omega)$; $x : [0,T]\times\Omega \to \mathbb{R}$, $(x; x_t) \in C([0;T]; H^1(\Omega)) \times C([0;T]; L^2(\Omega))$ and $v : (0,T)\times\Gamma \to \mathbb{R}^m$ belongs to $L^2(\Sigma)$.

In I. Lasiecka and R. Triggiani, (Regularity theory of hyperbolic equations with nonhomogeneous Neumann boundary conditions. II. General boundary data, J. Differential Equations, 94 (1991), pp. 112–164), the existence and regularity problems for the above problem was study in a case of f independent on x with f belonging to $L^1(0,T;L^2(\Omega))$. We assume that the function f is nonlinear in x and under some specific assumption on it we prove that solution of our equation $(x; x_t) \in C([0;T]; H^1(\Omega)) \times C([0;T]; L^2(\Omega))$. Next under additional assumption if we take a sequence $L^2(\Sigma) \ni v_k \to v_0$ then we show that the corresponding sequence x_k of solutions of our problem is convergent in some defined sense to solution x_0 of our problem with v_0 on boundary.

About exponential stability to systems with indefinite damping. **Jaime Muñoz Rivera** (Laboratório Nacional de Computação Científica, Brazil) IC/MT2043/0

We consider system with indefinite damping and we prove under suitable hypotheses that the solutions decays exponentially to zero as time goes to infinity. We apply this results to the wave equation, viscoelastic system of memory type and to the Timoshenko's system for linear and non linear equations.

IC/MP50/015: Qualitative properties of nonlinear hyperbolic equations. #2

On existence, uniform decay rates and blow up for solutions of the 2D wave equation with exponential source. **Marcelo Moreira Cavalcanti** (Universidade Estadual de Maringá, Brazil) IC/MT4546/015

This work is concerned with the study of the nonlinear damped wave equation

$$u_{tt} - \Delta u + h(u_t) = g(u) \qquad \text{in } \Omega\times]0,\infty[,$$

where Ω is a bounded domain of $\mathbb{R}^2$ having a smooth boundary $\partial\Omega = \Gamma$.

Assuming that g is a function which admits *exponential growth at the infinity* and, in addition, that h is a monotonic continuous increasing function with polynomial growth at the infinity, we prove both: global existence as well as blow up of solutions in finite time, by taking the initial data inside the potential well. Moreover, optimal and uniform decay rates of the energy are proved for global solutions.

3D convective Cahn–Hilliard equation. **Varga Kalantarov** (Koc University, Turkey) IC/MT2208/0

We consider the initial boundary value problem for the 3D convective Cahn–Hilliard equation with periodic boundary conditions. This gives rise to a continuous dynamical system on $\dot{L}^2(\Omega)$. Absorbing balls in $\dot{L}^2(\Omega), \dot{H}^1_{per}(\Omega)$ and $\dot{H}^2_{per}(\Omega)$ are shown to exist. Combining with the compactness property of the solution semigroup we conclude the existence of the global attractor. We then proove the existence of an exponential attractor. This approach also gives an explicit upper estimate of the dimension of the exponential attractor, and of the global attractor.

Uniform stabilization of the wave equation on compact surfaces. **Valéria Neves Domingos Cavalcanti** (Universidade Estadual de Maringá, Brazil) IC/MT4547/015

This work is concerned with the study of the wave equation on compact surfaces and locally distributed damping, described by

$$u_{tt} - \Delta_M u + a(x)\, g(u_t) = 0 \quad \text{ on } M\times]0,\infty[,$$

where $M \subset R^3$ is an oriented embedded compact surface without boundary, such that $M = M_0 \cup M_1$, where

$$M_1 := \{x \in M; m(x)\cdot\nu(x) > 0\} \quad \text{and } M_0 = M\backslash M_1.$$

Here, $m(x) := x - x^0$, ($x^0 \in R^3$ fixed) and ν is the exterior unit normal vector field of M.

For $i = 1,\cdots,k$, assume that there exist open subsets $M_{0i} \subset M_0$ of M such that they are umbilical, or more generally, that the principal curvatures k_1 and k_2 satisfy $|k_1(x) - k_2(x)| < \varepsilon_i$ (ε_i considered small enough) for all $x \in M_{0i}$. Moreover suppose that the *mean curvature* H of each M_{0i} is *non-positive* (i.e. $H \le 0$ on M_{0i} for every $i = 1,\cdots,k$). If $a(x) \ge a_0 > 0$ on an open subset $M_* \subset M$ that contains $M\backslash\cup_{i=1}^k M_{0i}$ and if g is a monotonic increasing function such that $k|s| \le |g(s)| \le K|s|$ for all $|s| \ge 1$, then uniform decay rates of the energy hold.

On the long time behavior on some viscoelastic problems. **Said Berrimi** (King Fahd University, Saudi Arabia) IC/MT4079/0

In this minisymposium we will talk about the asymptotic behavior of the following initial boundary value problem:

$$\begin{cases} u_{tt} - \Delta u + \int_0^t g(t-\tau)\Delta u(\tau)d\tau + h(x,u_t) = f(u), & \text{for } x \in \Omega\,, t \geq 0 \\ u(x,t) = 0, & \text{for } x \in \partial\Omega\,, t \geq 0 \\ u(x,0) = u_0(x)\,, \quad u_t(x,0) = u_1(x)\,, & \text{for } x \in \Omega\,. \end{cases}$$

We study first the problem when: $h(x,u_t) = a(x)u_t\,|u_t|^m$ and $f(u) = -\,|u|^\gamma\,u$, for $m \geq 0$, $\gamma \geq 0$, and Ω is a bounded regular domain of $\mathbb{R}^n$ with $(n \geq 1)$, with regular boundary. We will prove an exponential decay result under weaker conditions on both a and g. In fact we will allow a to vanish on any part of Ω (including Ω itself). As a consequence, the geometry restriction imposed on a part of $\partial\Omega$ by Cavalcanti *et al.* in one of his recent papers, is dropped. Our method of proof is based on the use of the perturbed energy technique. Next we consider the problem when $h(x,u_t) = 0$ and $f(u) = |u|^\gamma\,u$, for $\gamma > 0$. We first prove a local existence theorem, then we show that, for certain initial data and suitable conditions on g and γ, that this solution is global with an energy which decays exponentially or polynomially depending on the rate of the decay of the relaxation function g.

IC/MP111/015: Singular differential equations in applied mathematics.

Organiser: Nikolay Sidorov (Irkutsk State University, Russian Federation)
Co-organiser: Vladilen Trenogin (Moscow State Institute of Steel and Alloys, Russian Federation)
Co-organiser: Boris Loginov (Ulyanovsk State University, Russian Federation)

This minisymposium concentrates on solutions of singular nonlinear operator equations especially applicable to algorithmic analysis of nonlinear DEs in mechanics and mathematical physics, and also to Volterra models of nonlinear dynamical systems in heat-and-power engineering. The authors expound recent results on local and global existence theorems, regularization, and identification, including asymptotic, numerical and group theoretic methods. The use of such methods in various problems in mathematics, modern physics, heat-and-power engineering, and mechanics (elasticity theory, phase transitions) has given the authors rich possibilities for creativity and applications. We also intend to explore these methods to nonlinear models of manufacturing polymer and improve communication between scientists active in this field.

Subgroup structure of branching equations with crystallographic group symmetries. **Oleg Makeev** (Ulyanovsk State University, Russian Federation), Boris Loginov (Ulyanovsk State University, Russian Federation) IC/MT190/015

In branching theory of solutions of nonlinear equations symmetry breaking problems are known, when at the passage of bifurcational parameter its critical value, solutions with crystallographic groups symmetry arise. Symmetries of simple cubic lattice and planar crystallographic groups in stationary and dynamic branching with applications to mathematical physics problems (phase transitions in statistical theory of crystal; capillary-gravity surface waves) were considered in works of the authors [1, 2] and bibliography to them. Special attention in these works was payed to subgroup structure of bifurcating solutions with respect to point subgroup of simple cubic lattice and in particular relatively normal divisors of this subgroup.

Here for stationary and Andronov-Hopf bifurcations with symmetry of the highest crystallic classes of basic syngonies (crystallic systems) of crystallographic groups as semi-direct products of translations on the basic directions and point symmetry of lattices subgroup structure of relevant branching equations and bifurcating solutions dual to subgroup structure of such symmetries is investigated. Applications to phase transition theory in physics are given.

Variational splines for numerical solution of singular differential equations. **Igor Lutoshkin** (Ulyanovsk State University, Russian Federation), Vladimir Gorbunov (Ulyanovsk State University, Russian Federation), Name Martinenko (Ulyanovsk State University, Russian Federation) IC/MT752/0

The problem to be solved numerically is the initial one for an implicit ODE $F(\dot{x},x) = 0$, for $0 \leq t \leq T$ with $x(0) = x^0$, where $x \in \mathbb{R}^n$ and $F : \mathbb{R}^{2n} \to \mathbb{R}^n$ is a smooth transformation, in the case of arbitrary degeneracy of the Jacobi matrix $\partial F(\dot{x}(t),x(t))/\partial\dot{x}$ on the solution $x(t)$.

The proposed numerical method is based on the minimization of discrepancy of appropriate differential system and approximation of solution $x(t)$ by splines with moving knots. The first and second derivatives of the discrepancy functional on the spline's parameters can be effectively calculated with help of variational techniques and adjoint variables[1,2]. Here we present also a simpler techniques for direct differentiation of the discrepancy with respect to the parameters[3]. Comparative analytical and numerical analysis of different variants of the PM will be presented.

Analytical case of Lyapunov theorem about stability on first approximation. **Vladilen Trenogin** (Moscow State Institute of Steel and Alloys, Russian Federation) IC/MT135/015

Let X be real and complex Banach space. We consider the following differential equation:

$$\dot{x} = Ax + R(t,x). \quad (1)$$

Let here and below the following conditions are fulfilled
I. Let A be closed linear operator, mapping dense domain $D(A)$ in X and be generating operator of semigroup $U(t) = \exp(A(t)$ of class C_0. Semigroup U(t) is exponentially decreasing, i.e. there are constants $M > 0$ and $\alpha > 0$ such as for all $t \in \Re^+ = [0, +\infty)$ the following condition $||U(t)|| \le M\exp(-\alpha t)$ is fulfilled.
II. Nonlinear operator $R(t,x)$ is defined and continues wrt $t \in \Re^+$ and is analytical operator wrt x in point $x = 0$, $R(t,x) = \sum_{k=2}^{+\infty} R_k((t)x^k$, where $R_k(t)$ is k-linear bounded operators in X, and majourant numeric series has nonzero radius of convergence. Let call the classic solution of differential equation (1) on semi-axis $[0,\infty)$ the function $x = x(t)$ such that on $\Re^+$ this function is differentiable $x(t) \in D(A)$, and this function is solution of (1) on $\Re^+$. From condition II follows that DE (1) has trivial classic solution $x(t) = 0$. Apart from DE (1) we consider its first approximation the linear DE

$$\dot{x} = Ax. \quad (2)$$

For (1) and (2) we set the Couchy problem: to find their classic solutions, satisfies initial condition

$$x(0) = x_0. \quad (3)$$

If $R(t,x)$ do not depends on t, then DE (1) can be addressed as abstract dynamic system, its solutions as trajectories in phase space X, and point $x = 0$ - as equilibrium position of DE(1). We found the conditions when Lyapunov theorem about asymptotic stability of the classic trivial solution of DE (1) on its first approximation (2) is fulfilled.

For beginning we study the generalized solutions of Couchy problem (1),(3), i.e. continues solutions of integral equation

$$x(t) = U(t)x_0 + \int_0^t U(t-s)R(s,x(s))ds. \quad (4)$$

Definition. Let $\gamma > 0$. Space C_γ we call set of all abstract functions $x(t)$, defined and continues on semi-axis $\Re^+$ with operations of summation and multiplication on scalars and with results in X, for which the norm $|||x|||_\gamma = sup_{\Re^+}||x(t)||exp(\gamma t)$. The existence and uniqueness of generalized solution in space C_γ are proofed. This solution is analytic wrt x. For Ghelder operator $R_k(t)$ its proofed that generalized solutions is classical. We address the applications of this theory in problems for functional-differential equations and reaction-diffusion systems.

The theory of fundamental operator-functions of singular differential and integral operators in Banach spaces. **Michail Falaleev** (Irkutsk State University, Russian Federation) IC/MT232/015

We present principal results of the theory of fundamental operator-functions of singular differential and integral operators in Banach spaces. In explication of all theorems have employed the apparatus of generalized Jordan chains, the theory of generalized functions in Banach spaces, methods of semigroups with kernels. Such a mixture of diverse methods has given the possibility of investigating a wide class of singular differential and integral operator equations and partial differential operator equations with the Noether operator in the main part. In a number of classes of singular differential operator equations has been completely investigated.

Generalized solutions of integral-functional equations: construction and applications in power industry. **Nikolay Sidorov** (Irkutsk State University, Russian Federation), Denis Sidorov (Irkutsk, Russian Federation), Andrey Trufanov (Irkutsk State University, Russian Federation) IC/MT112/015

The method of construction of the generalized solutions with point carrier in singular part is proposed for nonlinear Volterra integral-functional equations

$$\int_0^t K(t,s)(x(s) + ax(\alpha s) + g(s^l x(s), s))\mathrm{d}s = f(t)$$

with sufficiently smooth kernel and function f; α and a are constants, and $0 < |\alpha| < 1$. The solution is constructed as a sum of singular and regular components. The special system of linear algebraic equations is used for construction of the singular component. The regular part is constructed by method of successive approximations combined with method of undetermined coefficients. The theorems of existence and uniqueness of the generalized solutions are proved. In general case the equation has a few bifurcating solutions. Such solutions can be constructed based on the results of this work in combination with known methods of bifurcation theory. Our results can be generalized on the systems and integral-operator equations, where kernel K is linear, and g is nonlinear mapping in Banach space. These results can be used in development of theory and application of differential-operator equations with Fredholm operator in main part[1] in problems of nonlinear dynamics and identification[2], and in other problems formulated in terms of the Volterra integral equations of the first kind.

Andronov–Hopf bifurcation and group symmetry for differential equations non-resolved under derivative. **Boris Loginov** (Ulyanovsk State University, Russian Federation), Oleg Makeev (Ulyanovsk State University, Russian Federation), Irina Konopleva (Ulyanovsk State University, Russian Federation), Youri Rousak (Ulyanovsk State University, Russian Federation) IC/MT175/015

In previous our articles [1, 2] in Banach spaces E_1, E_2 the general problem of branching theory $F(x,\varepsilon)=0$, $F(x_0,0)=0$ with Fredholm operator $B_{x_0}=-F'(x_0,0)$ under group symmetry conditions $\mathcal{K}_g F(x,\varepsilon)=F(L_g x,\varepsilon)$ ($g\in G$ is a Lie group) was studied in the assumptions about potentiality or pseudopotentiality of the relevant branching equation (BEq). On the base of the general theorem on the group symmetry inheritance by BEq the cosymmetric identity for BEq with Lie algebra operators and the theorem on the BEq reduction (dimension lowering) in the case of non-invariant kernel were proved. Applications to bifurcation symmetry breaking problems were given.

In this communication Andronov–Hopf bifurcation for the differential equations non-resolved under derivative $F(p,x,\varepsilon)=0$, $p=\frac{dx}{dt}$, $F(0,x_0,\varepsilon)\equiv 0$ with Fredholm operators $A_{x_0}=F'_p(0,x_0,0)$, $B_{x_0}=-F_{x_0}(0,x_0,0)$ under Lie group symmetry is investigated by the same methods under potentiality or pseudopotentiality of the relevant branching equation. The analogous BEq reduction theorem is proved.

IC/MP2055/042: Quantum kinetic theory for Bose–Einstein condensation.

Organiser: Weizhu Bao (National University of Singapore)
Co-organiser: Hailiang Li (Capital Normal University, PR China)

The experimental realization of Bose–Einstein condensates (BEC) in magnetically trapped atomic gases at ultra-low temperature has spurred great excitement in the atomic physics community and renewed the interest in studying the macroscopic quantum behavior of the atoms. Theoretical predictions of the properties of BEC like the density profile, collective excitations and the formation of quantized vortices can now be compared with experimental data. This dramatic progress on the experimental front has stimulated a wave of activity on both the theoretical and the numerical front. In this minisymposium, the speakers will address recent advancements in the following directions:

(a) Mathematical analysis for quantum Boltzmann equation for BEC at finite temperature;
(b) Efficient and accurate numerical methods for quantum Boltzmann master equation;
(c) Analysis and simulation for the Gross–Pitaevskii equation.

Nonlinear fluid-dynamic PDEs and multiscale analysis. **Shu Wang** (Beijing University of Technology, PR China) IC/MT1378/025

In this talk asymptotic limits and multiscale-analysis problems of some macroscopic fluid-dynamic partial differential equations are studied. These asymptotic limits conclude quasineutral limit and nonrelativistic limit etc. while the nonlinear Fluiddynamic PDEs concern some models like Euler-Maxwell system, e-MHD system, Euler-Poisson system, Navier-Stokes-Poisson system and Drift-Diffusion system etc, widely used in the area of applied sciences such as semiconductors, plasmas, fluid dynamics and so on, and they are full of multiscale phenomena. Some formal and rigorous convergence results are given and some new methods or ideas are reviewed.

Kinetic numerical methods for ideal quantum gas dynamics. **Joe Yang** (National Taiwan University) IC/MT538/025

Numerical methods for solving the ideal quantum gas dynamics based on the Bose–Einstein and Fermi–Dirac distributions are presented. Both concepts of beam scheme and kinetic flux splitting scheme are extended and generalized to the convectional quantum Boltzmann equation. Formulations for one to three spatial dimensions are derived. Numerical experiments to validate the methods are first demonstrated on one-dimensional problems. Higher-order methods based on modern high-resolution non-oscillatory interpolation are implemented for practical calculations. The possible extension to higher-order transport is outlined and some potential applications are also given.

MS number: IC/MP/025/R/226 Mathematical Analysis and Numerical Simulation for Bose-Einstein Condensation

Numerical methods and kinetic modelling of Bose–Einstein condensation. **Lorenzo Pareschi** (Università degli Studi di Ferrara, Italy) IC/MT2300/025

We develop efficient numerical schemes for the quantum Boltzmann equation that preserve the main physical features of the continuous problem, namely conservation of mass and energy, the entropy inequality and generalized Bose-Einstein distributions as steady states. These properties are essential in order to develop numerical methods that are able to capture the challenging phenomenon of bosons condensation. We also show that the resulting schemes can be evaluated with the use of fast algorithms. In order to study the evolution of the condensate wave function the Gross-Pitaevskii equation is presented together with some schemes for its efficient numerical solution and the possibility of coupling this equation with the quantum Boltzmann equation is discussed.

Fokker–Planck–Boltzmann near Maxwellian. **Hailiang Li** (Capital Normal University, PR China) IC/MT1633/025

We consider the Fokker–Planck–Boltzmann equation viewed as the Boltzmann equation with additional diffusion term in velocity space to describe for instance the transportation in thermal bath of binary elastic collisional particles. The strong solution for initial data near an absolute Maxwellian is proven to exist globally in time. The effect of the diffusion in phase space is investigated. It produces a diffusion process in velocity space and results in a heating process on the macroscopic fluid-dynamical observable, and accelerates the convergence of solutions to the equilibrium of self-similar Maxwellian at the faster time-decay rate than Boltzmann equation. Moreover, the Fokker–Planck–Boltzmann equation is shown to converge under an appropriate scaling strongly to the Boltzmann equation in the process of zero diffusion limit.

Bloch-decomposition-based pseudospectral methods for quantum dynamics with periodic potentials. **Shi Jin** (University of Wisconsin, Madison, USA) IC/MT1343/025

We present a new numerical method for accurate computations of solutions to (linear) one dimensional Schrödinger equations with periodic potentials. Our approach is based on the classical Bloch decomposition method and it proves to be superior to the mainly used time-splitting spectral schemes. Indeed it is is shown by the given numerical examples, that ou r method is unconditionally stable, highly efficient and allows for much larger time-steps than the the splitting schemes.

Strong confinement for the Gross-Pitaevski equation: energy solutions. **Naoufel Ben Abdallah** (Université Paul Sabatier Toulouse III, France) IC/MT4487/042

The limit of the Gross-Pitaevskii equation with a partial strong confinement is considered. The obtained system is an infinite system of coupled Schrödinger equations in the non strongly confined direction. In a previous work (see the talk of F. Méhats), strong local solutions are constructed for the limit system and convergence is proven. The aim of this talk is to construct global energy solutions for the limiting system. The proof is based on a an averaged Gagliardo Nirenberg inequality. Convergence issues will also be adressed. This is a work in collaboration with F. Castella and F. Méhats.

Semi-classical analysis for the nonlinear Schrödinger equation with potential. **Rémi Carles** (Universität Wien, Austria) IC/MT513/025

We present some results concerning the semi-classical limit of the nonlinear Schrödinger equation with a potential, in two cases:

- Weak nonlinearity, when the potential is an harmonic potential. This study includes the description of the solution beyond caustics.
- Strong nonlinearity and general sub-quadratic potential. There, we provide a WKB analysis (before caustics), for cubic, defocusing nonlinearities.

All these results are valid in any space dimension.

Travelling waves for the Gross-Pitaevskii equation. **Philippe Gravejat** (Université de Paris-Dauphine, France) IC/MT541/025

Our talk is devoted to some recent results about the travelling waves for the Gross-Pitaevskii equation. This equation, which is written as:

$$i\partial_t u = \Delta u + u(1 - |u|^2)\,,$$

for a function $u : \mathbb{R}^N \mapsto \mathbb{C}$, is a model for Bose-Einstein condensation, superfluidity or nonlinear optics. The travelling waves are the solutions of the form

$$u(t,x) = v(x_1 - ct, \ldots, x_N)\,,$$

for some speed $c \geq 0$. Such solutions are supposed to play an important role in the long-time dynamics of the Gross-Pitaevskii equation.

In a series of papers, C.A. Jones, S.J. Putterman and P.H. Roberts investigated both formally and numerically their existence and qualitative properties, which raised a lot of interesting questions. Thus, we present some recent results which confirm some of the predictions formulated by C.A. Jones, S.J. Putterman and P.H. Roberts. In particular, we focus on existence and non-existence results, and the asymptotics of the travelling waves.

IC/MP141/042: Navier-Stokes equations and related topics.

Organiser: Alex Mahalov (Arizona State University, USA)
Co-organiser: Yoshikazu Giga (University of Tokyo, Japan)

The proposed minisymposium will focus on recent advances in the mathematical theory of Navier-Stokes equations with applications to geophysical flows. The topics will include: long time behaviour and global regularity, problems with almost periodic initial data, rotating fluids, boundary layer problems in geophysics and other related topics.

Stability of the Ekman spiral. **Matthias Hieber** (TU Darmstadt, Germany) IC/MT4346/042

In this talk we consider the question whether the Ekman spiral on the halfspace is stable under L^2-perturbations. We prove in particular that the Ekman spiral is linearly stable in the L^2-setting provided the associated Reynoldsnumber is small enough.

Rotating fluids with free boundary. **Jürgen Saal** (Universität Konstanz, Germany) IC/MT4351/042

Motivated by various applications in Geophysics (e.g., boundary layer problems) and technology (e.g., spin-coating processes) we study the free boundary problem for the Navier-Stokes equations with rotation. We will present an approach which is based on a reduction to a quasilinear system with dynamic boundary conditions. A major difficulty is to handle the corresponding boundary symbols, which look rather complicated and are nonhomogeneous in space and time. Here we apply methods relying on maximal regularity and the Newton-polygon in order to prove the wellposedness of a suitable linearization. This leads to a local-in-time existence result for the nonlinear problem. This is a joint project with R. Denk, M. Geissert, M. Hieber, and O. Sawada.

On the stationary Navier-Stokes flow with Coriolis force term. **Shin'ya Matsui** (Hokkaido Information University, Japan) IC/MT4698/042

From a meteorological point of view, if Coriolis parameter Ω is sufficiently large, flow will be independent of vertical direction asymptotically, that is 3 dim. flow will close to 2 dim. flow as $|\Omega| \to \infty$. This phenomena is called the Taylor-Proudman theorem. Our main purpose is to study this singular perturbation problem.

In my talk I will give the following results. For a fixed Ω, we obtained several unique existence theorems of the Cauchy problem and boundary value problem ($\mathbb{R}^3_+$) in some function spaces which include periodic functions, almost periodic functions and some L^∞ functions. After this I will discuss some asymptotic behavior of stationary velocity field in $L^2(D)$ as $\Omega \to \infty$.

My talk is based on joint works with Prof. Y. Giga (University of Tokyo, Japan), Prof. K. Inui (Keio University, Japan), Prof. A. Mahalov (Arizona State University, USA) and Prof. J. Saal (University of Konstanz, Germany).

Bursting dynamics of the 3D Euler equations in cylindrical domains. **Basil Nicolaenko** (Arizona State University, USA), Alex Mahalov (Arizona State University, USA) IC/MT4703/042

A class of three-dimensional initial data characterized by uniformly large vorticity is considered for the 3D incompressible Euler equations in bounded cylindrical domains. The fast singular oscillating limits of the 3D Euler equations are investigated for parametrically resonant cylinders. Resonances of fast oscillating swirling Beltrami waves deplete the Euler nonlinearity. These waves are exact solutions of the 3D Euler equations. We construct the 3D resonant Euler systems; the latter are countable uncoupled and coupled $SO(3;\mathbf{C})$ and $SO(3;\mathbf{R})$ rigid body systems. They conserve both energy and helicity. The 3D resonant Euler systems are vested with bursting dynamics, where the ratio of the enstrophy at time $t = t^*$ to the enstrophy at $t = 0$ of some remarkable orbits becomes very large for very small times t^*; similarly for higher norms $\mathbf{H}^s$, $s \geq 2$. These orbits are topologically close to homoclinic cycles. For the time intervals where $\mathbf{H}^s$ norms, $s \geq 7/2$ of the limit resonant orbits do not blow up, we prove that the full 3D Euler equations possess smooth solutions close to the resonant orbits uniformly in strong norms.

On a linearized operator of the equation for Burgers vortices. **Yasunori Maekawa** (Hokkaido University, Japan) IC/MT4905/042

Burgers vortices have been used as a model which expresses concentrated vorticity fields in turbulence. Several numerical results indicate that as the vortex Reynolds number is increasing, the associated Burgers vortex becomes more radially symmetric and has simpler structures. The purpose of this talk is to give a mathematical explanation for these numerical observations by studying a linearized operator of the equation for Burgers vortices.

IC/MP4/043: Extended splitting methods for partial differential equations: theory and application.

Organiser: Juergen Geiser (Humboldt-Universität zu Berlin, Germany)

In the last years different decomposition methods have played an important role in the numerical solution of differential equations. Since the pioneer work on time splitting methods like ADI and exponential splitting formulae, many new concepts and strategies have been developed and utilized. The adaptive methods in the area of the Splitting methods associated with finite differences, finite elements, or adaptations have been used widely and have been shown to have powerful capabilities in solving different differential equation problems in various applications. The aim of this special issue is to highlight the new developments in the area. It will contain articles presenting the latest trends and research results in topics including, but not limited to:

- splitting for higher efficiency and accuracy;
- splitting for non-linear differential equations;
- stability and convergence of splitting methods;
- iterative and adaptive splitting methods;
- splitting methods in parallel and quantum computations.

We would like to bring experts in theory and application together and discuss the recent development and the possible future works.

Nonlinear iterative operator-splitting methods and applications for nonlinear parabolic partial differential equations. **Juergen Geiser** (Humboldt-Universität zu Berlin, Germany) IC/MT5/043

In this paper we concentrate on nonlinear iterative operator-splitting methods for nonlinear differential equations. The motivation arose from decoupling nonlinear operator equations in simpler operator equations. The decomposition in simpler equations allow to apply adaptive time-discretisation methods in each underlying time-scale. Therefore one can solve the equations more effectively and accurate. The underlying coupling of the splitting method is fulfilled with a relaxation, coming from the results of the previous time-steps. the adapted problems. We consider the consistency and stability analysis of the nonlinear iterative operator splitting method. The consistency analysis is based on linearisation An *a priori* error estimates is derived for the linearised case. Finally we discuss the iterative operator-splitting methods for the applications to multi-physics problems.

Numerical simulation of 2D wave-equations via split sine and cosine schemes. **Qin Sheng** (Baylor University, USA) IC/MT4163/043

The problem is motivated form a realistic problem in seismic sources and waves. The underlying wave equation can be treated as a dispersive nonlinear partial differential equation which allows soliton-type solutions. We present a sine- and cosine-splitting of the basic equation; see[1]. With a semi-discretisation we arrive at a system of second-order nonlinear ordinary differential equations. By the traditional sequential splitting in linear manner we obtain locally one-dimensional problems. A further modification, the so-called iterative-splitting method, is presented as an alternative approach which has greater accuracy; see[2]. The underlying numerical stability is discussed. Numerical applications are given for demonstrations. Finally we discuss the extension to other multi-dimensional nonlinear wave simulations.

Time-parallel time integration methods for ODEs and PDEs. **Martin Gander** (Université de Genève, Switzerland) IC/MT1539/043

Time dependent problems are often solved using time marching schemes. Such schemes remain effective on parallel computers as long as each time step is costly enough for an effective parallelization in space. If not, parallelism in time could alleviate the situation, but is it possible to do useful computations at future time steps before the current time step results are known ?

I first present a historical overview of algorithms that were proposed over the last 40 years to obtain a certain amount of time parallelism. I will then introduce a general time domain decomposition method based on multiple shooting, which permits the parallel in time computation of solutions of time dependent problems. This time domain decomposition method contains more recent time parallel algorithms like the parareal algorithm. A convergence analysis reveals superlinear convergence of the method on bounded time intervals, and linear convergence on unbounded time intervals under certain conditions. I will illustrate the results with numerical experiments.

Efficient, adaptive and process-preserving modified Newton's method for solving reactive multicomponent transport problems. **Alexander Prechtel** (Universität Erlangen-Nürnberg, Germany) IC/MT2283/043

In the context of hydrogeochemical multicomponent transport problems coupled via reaction rates the fully implicit solution of the (discretized) problem can be computationally expensive, but it avoids the consistency errors inherent in the popular operator splitting approaches which seperate transport and reaction operators.

The efficiency of the process-preserving, globally implicit approach can be enhanced however by using as nonlinear solver a modified Newton's method.

Therefore the reaction network is analysed to neglect terms in the Jacobian whith the aim to decouple species equations on the level of the linear solver without deteriorating the quadratic performance of the global, process-preserving Newton iteration. This is possible, e.g., in the case of slow kinetics and/or small concentrations. A flexible list oriented, componentwise linear sparse matrix solver can adapt and change the coupling strategy of the groups of unknowns potentially in every iteration.

Numerical results of artificial and realistic case studies of reactive contaminant transport are presented that demonstrate the potential of the approach.

A splitting moving-mesh method for 2D and 3D quenching and blow-up problems. **Ping Lin** (National University of Singapore) IC/MT3274/043

We study the numerical solution of multi-dimensional reaction-diffusion differential equations with a nonlinear force term over a rectangular domain. The equations may generate quenching or blow-up singularities depending on the force term. We will first focus on the quenching case to develop a variable temporal step splitting method on an adaptive moving mesh in space. The temporal and spatial adaptation is implemented based on parameterized arc-length estimations of the time derivative of the solution which will approach infinity when quenching takes place at certain spatial point. The multi-dimensional problem is split into a few one-dimensional problems so that the mesh moving can be done under a one-dimensional setting. The splitting procedure can also be parallelized so that the computational time is significantly reduced. The physical monotonicity of the solution and localized linear stability of this variable step adaptive scheme are analyzed. We also indicate that usual linearized stability analysis for the quenching problem is not appropriate when it is close to the quenching time. Thus a mathematically equivalent linearized problem is introduced to justify the stability. Finally we provide some numerical examples to demonstrate the viability and efficiency of the method for the quenching problem as well as other blow-up problems. We will also show the reduction of computational time when parallelly implementing the algorithm on a multi-CPU computer.

Stability and accuracy of higher-order operator splitting methods for parabolic equations. **Andrew Sornborger** (University of Georgia, USA) IC/MT3773/043

The Sheng-Suzuki theorem states that all exponential operator splitting methods of order greater than 2 must contain negative time integration. There have been claims in the literature that higher-order splitting methods for deterministic parabolic equations are unstable due to this fact. We show stability for a class of higher-order splitting methods for integrating deterministic parabolic equations. We note that problems with backwards time integration will still exist for stochastic integration methods for which information is lost and backward timesteps become ill-defined. Therefore, completely positive splitting methods, such as those developed by Chin, still have an important place. We present numerical results from first-, second-, third- and fourth-order methods showing that the error becomes increasingly small as the order increases.

On the local error of splitting approximations of reaction-diffusion equations with high spatial gradients. **Stéphane Descombes** (Ecole Normale Superieure de Lyon, France), Thierry Dumont (Université Claude Bernard Lyon 1 43 boulevard du, France), Violaine Louvet (Université Claude Bernard Lyon 1 43 boulevard du, France), Marc Massot (Ecole Centrale de Paris, France) IC/MT3784/043

In this talk we present some results on the approximation by splitting techniques of the ordinary differential equation $\dot{U} + AU + BU = 0$, $U(0) = U_0$ with A and B two matrices. We assume that we have a stiff problem in the sense that A is ill-conditionned and U_0 is a vector which is the discretization of a function with a very high derivative. This situation may appear for example when we study the discretization of a partial differential equation. We show some error estimates for two general matrices and in the stiff case, where the estimates are independent of U_0 and the commutator between A and B. As an example, a particular attention is paied to the study of the approximation of parabolic waves.

Propagation of high-intensity light in semiconductors. **Leonel Gonzalez** (General Dynamics Corporation, USA), Qin Sheng (Baylor University, USA), Shekhar Guha (Air Force Research Lab., Wright-Patterson AFB, USA) IC/MT4182/043

For photon energies below the bandgap, semiconductors exhibit high transparency. Propagation of light through this transparent medium can be described by a set of coupled, inhomogeneous, partial differential equations. For light collimated over the length of the sample, these equations can be written as:

$$\frac{\partial I}{\partial z} = -\left(1 + \frac{\Delta n}{n_0}\right)\left(\alpha I + \beta I^2 + \sigma_a N I\right) \quad (1)$$

$$frac\partial N\partial t = \frac{\beta I^2}{2h\nu} - \frac{N}{\tau} \quad (2)$$

$$Deltan = \sigma_r N + \frac{dn}{dT}\Delta T \quad (3)$$

$$frac\partial T\partial t = -\frac{1}{c_p}\frac{\partial I}{\partial z} \quad (4)$$

These equations describe the change in irradiance, I, as a function of the propagation direction z through the medium. The

irradiance source considered here is a laser having Gaussian spatial and temporal distributions, $I(r,t)$. Although the linear, single photon absorption α is typically low, under high irradiances, as during laser illumination, the contributions due to two photon absorption, β, and from free carriers, N, are significant.

A rate equation governs the generation of free carriers during the pulse. The carriers have a recombination lifetime, τ, which may be of the same order as the temporal duration of the laser pulse. Remaining equations describe the changes in refractive index, Δn and temperature, T. The parameter, σ_r is the refractive cross section of the free carriers, the thermo-optic coefficient of the medium is given by $\frac{dn}{dT}$, and the specific heat capacity is c_p. Not implicitly stated are the temperature dependencies of β, N, σ and τ.

To solve this set of coupled equations, a split-step finite difference scheme is used. For a given incident $I(r,t)$, the beam is propagated in space and time through the medium. At the output, the beam is temporally and spatially integrated yielding the total transmitted energy, which can be readily measured in the lab. Theoretical results and comparison with actual transmission measurements will be presented.

IC/MP2549/043: Dynamical models and game theory.

Organiser: Alberto Pinto (Universidade do Porto, Portugal)

See IC/MP339/015 on page 404 (Industrial Organization and Game Theory).

Edgeworthian economies. **Miguel Ferreira** (Universidade do Porto, Portugal) IC/MT881/043

General equilibrium theory assumes an interaction between individuals that is both global and anonymous. More, it presumes the existence of a "magic hand"which guides the way the market behaves. We study the effects of introducing a direct exchange mechanism between individuals in terms of dynamic models of an Edgeworthian exchange economy. We analyse the case where only two goods are traded and we assume random meeting between the market participants. We classify types of participants to study the effect of greed and we verify that greed is not always good and the minority wins more. We also present an evolutionary type model where consumers adapt to the market by temporally adjusting their individual preferences and their greediness.

Optimal investments to increase the market of the firms in repeated Cournot competition. **Bruno Oliveira** (Universidade do Porto, Portugal), Alberto Pinto (Universidade do Porto, Portugal), Fernanda Ferreira (Instituto Politecnico do Porto, Portugal), Flávio Ferreira (Instituto Politecnico do Porto, Portugal), Miguel Ferreira (Universidade do Porto, Portugal) IC/MT901/043

We present a deterministic dynamical model on the market size of Cournot competitions, based on Nash equilibriums of R&D investment strategies to increase the market of the firms at every period of the game. We study the transients and the asymptotic dynamics on the market sizes of the duopoly competition and their profound implications on the profit and persistence of the firms in the market. By adding uncertainty to the R&D investment strategies, we get a new stochastic dynamical model and we analyse the importance of the uncertainty to reverse the initial advantage of one firm with respect to the other.

International duopoly with unknown costs. **Hugo Sequeira** (Universidade do Porto, Portugal), Alberto Pinto (Universidade do Porto, Portugal), Fernanda Ferreira (Instituto Politecnico do Porto, Portugal) IC/MT905/015

Consider two identical countries. Each country has a government that chooses a tariff rate, a firm that produces output for both home consumption and export, and consumers who buy on the home market from either the home firm or the foreign firm. There is no other producer of this product for these two markets. We suppose that each firm has two different technologies, and chooses one of them following a common knowledge binary probability distribution. The utilization of one or the other technology affects the unitary production cost. The timing of the game is as follows: First, the governments simultaneously choose tariff rates. Then, both firms simultaneously choose quantities for home consumption and for export. We determine the Bayesian Nash equilibrium, and we analyse the advantage profits, for the firms and for the consumers, of the utilization of the technology with most expensive cost versus the utilization of the technology with cheapest cost. We also analyse the effect of the degree of differentiation of the goods on the equilibrium levels.

Flexibility and leadership advantages in a model with uncertain demand. **Fernanda Ferreira** (Instituto Politecnico do Porto, Portugal), Flávio Ferreira (Instituto Politecnico do Porto, Portugal), Alberto Pinto (Universidade do Porto, Portugal) IC/MT855/043

The Stackelberg model (1934) is one of the most widely-used models in industrial organization for analysing firms' behavior in a competitive environment. It studies the strategic situation where firms sequentially choose their output levels in a market. The question we ask is: Do first movers really have strategic advantage in practice? The belief of first-mover advantage was widely held among entrepreneurs and venture capitalists, but is now questioned by numerous practitioners. In this paper, we extend Liu's (2005) results by focus not only on the effects of the market demand uncertainty, but also on product differentiation, to explain the advantages and disadvantages of being the leading firm. Usually, the followers in markets get more market information than first movers before sinking their investments. In some industries that we consider to have fairly stable and predictable market demand, the pioneering firm tends to be the biggest player. However, if a market has a high degree of uncertainty, the followers can wait and see the customers' response to the new product introduced by the first movers, as well as move along the "differentiation curve" of innovation.

As in Liu's (2005) model, we consider that only the first mover (leading firm) faces demand uncertainty. The demand uncertainty is given by a random variable uniformly distributed, with mean μ and standard deviation σ characterizing the *demand uncertainty parameter* $\theta = (\mu + \sqrt{3}\sigma)/(\mu - \sqrt{3}\sigma)$. By the time the second mover chooses its output level, that uncertainty is resolved. Therefore, the leading firm possesses first-mover advantage, but the second mover enjoys an informational advantage because it can adjust the production level after observing the realized demand (flexibility). We study the advantages of flexibility over leadership as the degree $0 < \gamma \leq 1$ of the differentiation of the goods changes, where γ attains the value 1, if the goods are homogeneous, and tends to 0, if the goods are close to independent goods. We find explicit functions I_γ and J_γ, in terms of the degree of differentiation, characterizing the demand uncertainty parameter θ for which the leading firm looses its advantage for some realizations of the demand random variable. We show that the leading firm looses its advantage for high values of the demand intercept, if the demand uncertainty parameter θ is greater than I_γ, and for low values of the demand intercept, if the demand uncertainty parameter θ is greater than J_γ. Hence, for high values of the demand uncertainty parameter θ only in an intermediate zone of the realized demand does the first mover preserve its advantage.

IC/MP133/045: Free-boundary problems and their applications.

Organiser: Patrick Guidotti (UC Irvine, USA)
Co-organiser: Gieri Simonett (Vanderbilt University, USA)

This minisymposium features talks about both the theory of free-boundary problems and their applications to biology, chemistry and fluid dynamics.

Analytic solutions for the classical Stefan problem. **Gieri Simonett** (Vanderbilt University, USA) IC/MT3825/045

In this talk I will consider the classical one- or two-phase Stefan problem, where the free boundary is given as the graph of a function. Under mild regularity assumption on the initial data it will be shown that the problem admits a local solution that is analytic in space and time. The approach is based on optimal regularity results for an appropriate linearized problem, and on a scaling-translation argument in conjunction with the implicit function theorem.

Asymptotic behaviour of solutions of a multidimensional moving-boundary problem. **Joachim Escher** (Leibniz Universität Hannover, Germany) IC/MT1694/045

Of concern is a moving boundary problem modelling the growth of multicellular spheroids or in vitro tumors. This model consists of two elliptic equations describing the concentration of a nutrient and the distribution of the internal pressure in the tumor's body, respectively. The driving mechanism of the evolution is governed by Darcy's law. Finally surface tension effects on the moving interface counteract the internal pressure. Based on a centre manifold analysis, we prove that if the initial domain is sufficiently close to a Euclidean ball in the $C^{m+\mu}$-norm with $m \geq 3$ and $\mu \in (0,1)$, then the solution exists globally and the corresponding domains converge exponentially fast to some (possibly translated) ball, provided the surface tension coefficient γ is larger than a positive threshold value γ^*. In the case $0 < \gamma < \gamma^*$ the radially symmetric equilibrium centred at the origin is unstable.

A class of free-boundary problems with onset of a new phase. **Patrick Guidotti** (UC Irvine, USA) IC/MT2530/045

In this talk we shall address the well-posedness of a class of diffusive Free Boundary Problems characterized by the initial onset of a new phase. A novel regularity theory for linear singular elliptic and parabolic problems will be presented which is needed in the construction of a solution of the nonlinear coupled systems stemming from the considered class of Free Boundary Problems.

IC/MP3800/045: Free-boundary problems and their applications, II.

Organiser: Patrick Guidotti (UC Irvine, USA)
Co-organiser: Gieri Simonett (Vanderbilt University, USA)

This is an extension of the minisymposium IC/MP133/045 on page 340 since it has a total of 11 speakers.

On the regularity of a constrained system and applications to phase change problems. **Jose-Francisco Rodrigues** (Universidade de Lisboa, Portugal) IC/MT3903/045

The phase field approach for multi-phase systems leads to consider diffusion problems for the vector order parameter under constrains of the Gibbs simplex type. For certain potentials, these problems may be considered as special cases of a class of parabolic variational inequalities associated with convex sets defined by a system of obstacle type constraints. Under natural assumptions on these constraints, we use the Lewy-Stampacchia inequalities together with a simple iteration argument to show that the regularity of the solution is the same as the one corresponding to linear parabolic systems of second order. Special cases of constraints for ternary mixtures, for a system of two grains and for a diffuse interface model for simultaneous order-disorder and phase separation illustrate those estimates. This is a joint work with Lisa Santos.

Instability in a flame ball problem. **Luca Lorenzi** (Università degli Studi di Parma, Italy) IC/MT3833/045

In [1] the authors proposed a mathematical model to describe the combustion of a gaseous mixture with dust in a microgravity environment. Such a model gives rise to the following FBP in the unknowns γ, θ, u and the moving domain Ω:

$$\begin{cases} \gamma_t(t,x) = \dfrac{1}{\mathrm{Le}}\Delta\gamma(t,x), & t>0, \quad x \in \mathbb{R}^3 \setminus \overline{\Omega(t)}, \\ \gamma(t,x) = 0, & t>0, \quad x \in \Omega(t), \\ \vartheta_t(t,x) = \Delta\vartheta(t,x) + \beta u(t,x), & t>0, \quad x \notin \partial\Omega(t), \\ \Delta u(t,x) - 3\alpha^2 u(t,x) + \alpha\Delta\vartheta^4(t,x) = 0, & t>0, \quad x \notin \partial\Omega(t). \end{cases} \tag{1}$$

On $\partial\Omega(t)$, the following jump conditions are prescribed:

$$[\vartheta(t,\cdot)] = [\gamma(t,\cdot)] = 0, \qquad -\left[\frac{\partial\vartheta}{\partial\nu}(t,\cdot)\right] = \frac{1}{\mathrm{Le}}\left[\frac{\partial\gamma}{\partial\nu}(t,\cdot)\right], \qquad t>0, \tag{2}$$

$$\frac{1}{\mathrm{Le}}\left[\frac{\partial\gamma}{\partial\nu}(t,\cdot)\right] = F(\vartheta(t,\cdot)) \qquad u(t,\cdot)+\alpha\vartheta(t,\cdot) \ \text{ smooth}, \qquad t>0, \tag{3}$$

Moreover, at infinity it is assumed that

$$\gamma(t,x) \to \gamma_f, \quad \vartheta(t,x) \to \vartheta_f, \quad u(t,x) \to 0 \quad \text{as } |x| \to \infty, \qquad t>0. \tag{4}$$

The variables ϑ and γ correspond, respectively, to the temperature and the fuel mass fraction of the reactant, whereas u is a measure of the radiation flux. ϑ_f and γ_f denote the temperature and the mass fraction away in the fresh region. The parameters Le (Lewis number), α and β denote respectively the ratio between conductivity and diffusivity, the opacity of the medium and the ratio between the radiative and the diffusive flux. The space variable x belongs to $\mathbb{R}^3$, $\partial\Omega(t)$ is the free boundary variable corresponding to the flame front and $F(\vartheta(t,\cdot))$ is the reaction rate evaluated at $\partial\Omega(t)$, a simplified Arrhenius law, F being a smooth positive and increasing function. Finally, ν denotes the unit outward normal to $\partial\Omega(t)$.
As it has been shown in [1], Problem (1)-(4) admits steady state solutions (i.e., flame balls).
In this talk we show that, for particular values of the parameters α, β and Le, such flame balls are unstable with respect to smooth (and smooth) radial perturbations.
This is a joint work with V. Gujonne (Vrije Universiteit Amsterdam, The Netherlands)

Bifurcation of a free boundary problem for the Stokes equation: application to tumor growth. **Avner Friedman** (Ohio State University, USA) IC/MT1577/045

We introduce a free boundary problem for a system of PDEs consisting of the Stokes equation, several by parabolic equations and a diffusion equation. The system represents a growing tumor in fluid-like tissue. A biological parameter λ represents the cell-to-cell adhesiveness of the tumor cells. We show that a spherical stationary tumor is asymptotically stable if $\lambda > \lambda_0$ and is unstable if $\lambda < \lambda_0$. This is joint work with Bei Hu.

Calculating deposit formation in the pipelining of waxy crude oils. **Antonio Fasano** (Università di Firenze, Italy) IC/MT1271/045

Analogue of the Rudin–Osher–Fatemi total variation model for fairing surfaces. **Matthew Elsey** (University of Michigan at Ann Arbor, USA), Andrea Bertozzi (University of California, Los Angeles, USA), Selim Esedoglu (University of Michigan, Ann Arbor, USA) IC/MT2595/045

Denoising of surfaces is an important problem in computer graphics applications. The goal is to remove noise and oscillations from the surface without rounding out important discontinuties in the normals (i.e. creases on the surface) such as the sharp edges of a cube. We show that the total variation based image denoising model of Rudin, Osher, and Fatemi has a very natural analogue for surface denoising.

Analysis and simulation of two-phase flows with soluble surfactant. **Dieter Bothe** (RWTH Aachen, Germany), Jan Pruess (Universität Halle–Wittenberg, Germany) IC/MT2680/045

Fluid particles like drops or bubbles play a prominent role in numerous applications. In such systems, at least one of the phases often contains surface active agents - unmeant as a contamination or by determined addition to increase the process efficiency - which preferentially adsorb at the interface due to minimization of free surface energy. The coverage with surfactant has a pronounced effect on the surface tension, hence on the stress balance at the interface which can lead to so-called Marangoni effects. This talk covers the mathematical modeling and analysis of such two-phase flows as well as their numerical simulation based on the Volume-of-Fluid (VOF) method.

Oil trapping in porous media. **Ben Schweizer** (Universität Basel, Switzerland) IC/MT1745/045

We consider the one-dimensional degenerate two-phase flow equations as a model for water-drive in oil recovery. The effect of oil trapping is observed in strongly heterogeneous materials with large variations in the permeabilities and in the capillary pressure curves. In such materials, a vanishing oil saturation may appear at interior interfaces and inhibit the oil recovery. We introduce a free boundary problem that separates a critical region with vanishing permeabilities from a strictly parabolic region and give a rigorous derivation of the effective conservation law.

IC/MP287/045: Free-boundary problem: moving interfaces and applications.

Organiser: Bo Su (Iowa State University, USA)

This minisymposium is to provide a forum to foster academic exchange and collaborations among active researchers in the area to address the fundamental problem in moving interface problem and their applications in material science, mathematical biology.

Bifurcation from stability to instability in a free boundary problem for elliptic–parabolic–hyperbolic system. **Avner Friedman** (Ohio State University, USA) IC/MT1576/045

We introduce a free boundary problem for a system of PDEs consisting of one diffusion equation, one parabolic equation, and several hyperbolic equations. The system represents tumor growth in a porous medium. The system has a family of stationary symmetry breaking bifurcation branches, with parameter μ representing the "aggressiveness" of the tumor. We study the asymptotic stability of the spherical solution, and determine the critical value of μ when the stability is lost. This is joint work with Bei Hu.

Gelification of waxy crude oils. **Antonio Fasano** (Università di Firenze, Italy), Mario Primicerio (Università degli Studi di Firenze, Italy) IC/MT3759/045

Mineral oils with a high content of heavy hydrocarbons are characterized by a peculiar thermodynamical behaviour influencing their rheology. Here we consider a saturated solution of one heavy in one light hydrocarbon, with the aim of describing two phenomena: (i) the segregation of solid crystals below some known temperature, (ii) the transition of the solution to a gel at an even lower temperature. When such phenomena take place in a prescribed thermal gradient they give raise to a complicated mass transfer process, due to the temperature dependence of the saturation concentration, with the formation of a gel on the cold wall and the formation of a region (necessarily unsaturated), completely depleted of crystals,

near the warm wall. Thus we have two free boundaries (the gelification front and the crystal depletion front). Two species are evolving: the solute concentration and the concentration of crystals. The crystals are supposed not to migrate and to exchange mass with the solution according to some (linear) kinetics. The solute can diffuse in the solution (i.e. prior to gelification), but is immobilized in the gel. Gelification occurs when the total concentration (solute+crystals) reaches a given temperature dependent threshold. Some results for the one-dimensional problem are presented.

Moving interfaces in heterogeneous oscillating media. **Panagiotis Souganidis** (University of Texas at Austin, USA) IC/MT3797/045

In this talk I will review recent results about the motion of interfaces in heterogeneous oscillating media. In particular I will present homogenization results for interfacial motions in periodic, almost periodic and random media.

Two-dimensional Riemann problems for systems of conservation laws. **Yuxi Zheng** (Pennsylvania State University, USA) IC/MT3793/045

We will report progress on the construction of solutions to the Riemann problem for the Euler system in 2-D and other systems such as the pressure gradient system. The results will include the interaction of binary planar waves, shock reflection on ramps, and others.

IC/MP287/045: Free-boundary problem: moving interfaces and applications. #2

Continuity of the saturation for the Buckley–Leverett system. **Emmanuele DiBenedetto** (Vanderbilt University, USA), Vincenzo Vespri (Università degli Studi di Firenze, Italy), Ugo Gianazza (Università degli Studi di Pavia, Italy) IC/MT4414/045

We establish local continuity of the saturation for the Buckley-Leverett system of two immiscible fluids in a porous medium, with no assumption on the behavior of the pressure near the interfaces.

The sub-elliptic obstacle problem: $C^{1,\alpha}$ regularity of the free boundary in Carnot groups of step two. **Donatella Danielli** (Purdue University, USA) IC/MT4767/045

The sub-elliptic obstacle problem arises in various branches of the applied sciences, e.g., in mechanical engineering and robotics, mathematical finance, image reconstruction and neurophysiology. In recent work by Danielli, Garofalo and Salsa, it was proved that weak solutions to the sub-elliptic obstacle problem in a Carnot group belong to the Folland-Stein (optimal) Lipschitz class $\Gamma_l^{1,1}oc$ (the analogue of the well-known $C_l^{1,1}oc$ interior local regularity for the classical obstacle problem). However, the regularity of the free boundary remained a challenging open problem. In this talk we will show that, in Carnot groups of step r = 2, the free boundary is (Euclidean) $C^{1,\alpha}$ near points satisfying a certain thickness condition. This constitutes the sub-elliptic counterpart of a celebrated result due to Caffarelli.

On the regularity of the free boundary for the classical Stefan problem. **Gieri Simonett** (Vanderbilt University, USA) IC/MT4469/045

The regularity of the temperature and the free boundary for the Stefan problem has attracted much attention over the last 3 decades or so.

In this talk I will consider the classical one- or two-phase Stefan problem where the free boundary is represented as the graph of a function.

Under mild regularity assumptions on the initial data it will be shown that the problem admits a local solution that is analytic in space and time.

The approach is based on optimal regularity results for a linearized problem, and on a scaling-translation argument in conjunction with the implicit function theorem.

Front propagation in polymer crystallization. **Bo Su** (Iowa State University, USA) IC/MT1180/045

The aim of this talk is to show the global existence of weak solutions for a moving boundary problem arising in the non-isothermal crystallization of polymers. The main features of our works are (i) the moving interface is shown to be of co-dimension one; (ii)finite Hölder continuous propagation speed yields an intrinsic estimate of finite co-dimension one Hausdorff measure of the moving interface for every time t in two space dimension; (iii) based upon (ii), we prove Hölder continuity of the temperature u by a decomposition argument.

IC/MP317/046: Control problems for fluidodynamic models.

Organiser: Fabio Ancona (Università di Bologna, Italy)
Co-organiser: Benedetto Piccoli (Consiglio Nazionale delle Ricerche, Italy)

The theory of weak solutions of hyperbolic conservation laws received many foundamental contributions in the last years. In particular, the well-posedness theory for the Cauchy problem and for the mixed initial-boundary value problem is now well established in the case of systems in one space dimension. On the other hand, the study of these equations from the point of view of control theory is still at an early stage. The interest on such problems is motivated by applications to traffic flow models, multicomponent chromatography, as well as in problems of oil resevoir simulation and gas dynamic. Another related interesting area of research regards the control of equations over networks, to address application domain as car traffic flow, telecommunication, irrigation channels, etc.

When studying the effect of the boundary data treated as controls acting on the solutions of a conservation law one cannot expect to achieve in general complete controllability results within the space of discontinuous weak solutions, due to the particular wave-front structure of the solutions of such systems. It is then more appropriate to consider the problem of asymptotic stabilization of an hyperbolic system with boundary controls. Of particular interest for applications are general boundary controllability and stabilizability problems where the control acts only on some of the boundary conditions.

Another relevant direction in which it is being pursued the investigation of hyperbolic control problems is the study of necessary conditions for the optimality of a weak solution where the controls may act through the boundary conditions as well as through the source term of the balance laws. Here, the

main source of difficulties stems from the fact that the *input-to-trajectory map* that associates to a given control the corresponding solution may not be differentiable in any natural Banach space. For this reason to tackle such problems it has been crucial to introduce a suitable variational structure on the flow generated by conservation laws.

On boundary control for hyperbolic conservation laws. **Fabio Ancona** (Università di Bologna, Italy) IC/MT1062/046

We are concerned with the effect of boundary conditions on the solution of an hyperbolic system of conservation laws in one-space variable, from the point of view of control theory. Namely, given a fixed initial condition, we assume that the evolution of the system can be affected by an external controller acting through the boundary conditions and thus we shall regard the boundary data (or a partial number of their components) as boundary input controls. We will discuss some results concerning the finite time exact controllability and the asymptotic stabilizzability of the system relative to general boundary conditions. Moreover, we shall address the problem of determining an optimal solution of an hyperbolic system of balance laws relative to certain classes of cost functionals with boundary or distributed controls.

Control of the Camassa–Holm equation. **Olivier Glass** (Université Paris VI, France) IC/MT2647/046

The Camassa-Holm equation is a model of unidirectional waves at a free surface under the influence of gravity. We consider this equation in the circle $\mathbb{S}$, with a distributed control in a subdomain ω: for (t,x) in $[0,T]\times\mathbb{S}$,

$$u_t - u_{txx} + 2\kappa u_x + 3uu_x = 2u_x u_{xx} + uu_{xxx} + g(t,x)\mathbf{1}_\omega(x).$$

We study the controllability and the stabilization problems via the control g.

Controllability of the KdV equation. **Sergio Guerrero Rodríguez** (Université Paris VII, France) IC/MT2224/046

We present some controllability results concerning the linear KdV equation:

$$u_t+\nu u_{xxx}+Mu_x = 0 \quad (t,x)\in(0,T)\times(0,1),\ u(0,x)=u_0 \quad x\in(0,1)$$

In a first result we prove the null controllability of this equation for any $u_0 \in L^2(0,1)$ and $u(t,1) = u_x(t,1) = 0$. In a second result, we prove that whenever $T > C/|M|$ with C large but independent of M, the cost of the null controllability of the previous equation (same notion as above) is bounded with respect to ν as long as ν is small enough.

As a consequence of the previous results, we deduce an exact controllability result for the same equation and some local controllability results for the KdV (nonlinear) equation.

Asymptotic stabilization of one dimensional hyperbolic conservation laws. **Andrea Marson** (Università degli Studi di Padova, Italy), Fabio Ancona (Università di Bologna, Italy) IC/MT1829/046

Consider a strictly hyperbolic system of conservation laws in one space dimension on the interval $]0,1[$

$$\partial_t u + \partial_x f(u) = 0\,, \qquad u\in\mathbb{R}^n\,, \quad x\in]0,1[\,. \tag{1}$$

The main assumption is that the eigenvalues $\lambda_1(u),\dots,\lambda_n(u)$ of $Df(u)$ are bounded away from zero

$$\lambda_1(u) < \cdots < \lambda_p(u) < 0 < \lambda_{p+1}(u) < \dots \lambda_n(u)\,.$$

Moreover, we assume that the classical Lax conditions on genuine nonlinearity or linear degeneracy of the characteristic fields hold. Let an initial condition $u(0,x) = u_0(x)$ be given, together with a couple of boundary conditions at $x = 0$ and $x = 1$

$$b_0(u(t,0)) = 0\,, \qquad b_1(u(t,0)) = g(\alpha(t)) \in \mathbb{R}^p\,. \tag{2}$$

Here b_0, b_1 and g are smooth functions and $\alpha = \alpha(t) \in \mathbb{R}^k$, $n - p \le k \le p$, is a control function. It is well known that in general we can not obtain any result controllability in finite time [1]. Hence, we turn our attention to the problem of stabilizing the system around an equilibrium, i.e. a state $\tilde{u} \in \mathbb{R}^n$ such that

$$b_0(\tilde{u}) = 0\,, \qquad b_1(\tilde{u}) = g(\tilde{\alpha}) \quad \exists\tilde{\alpha}\in\mathbb{R}^k\,.$$

Provided the initial datum u_0 is sufficiently close to $\tilde{u}$ in L^∞ norm, and assuming that $\operatorname{rank} Dg(\alpha) = k$ for any α and other technical hypotheses on b_0 and b_1, we construct a control α and sequence of front tracking approximations converging to a solution $u = u(t,x)$ of (1)-(2) that approaches $\tilde{u}$ uniformly (in x) as $t \to +\infty$.

Traffic-like models for supply chains. **Pierre Degond** (Université Paul Sabatier Toulouse III, France) IC/MT793/046

We consider a supply chain consisting of a sequence of buffer queues and processors with certain throughput times and capacities. Based on a simple rule for releasing parts; i.e., batches of product or individual product items, from the buffers into the processors we derive a hyperbolic conservation law for the part density and flux in the supply chain. The conservation law will be asymptotically valid in regimes with a large number of parts in the supply chain. Solutions of this conservation law will in general develop concentrations corresponding to bottlenecks in the supply chain.

(Joint work with C. Ringhofer and D. Armbruster (Arizona State University

Optimal control of flows in 1D networks. **Günter Leugering** (Universität Erlangen–Nürnberg, Germany) IC/MT1783/046

We consider optimal control problems for flows in networked domains, like gas-, water- or traffic networks. In particular we consider the control of traffic on road networks and water flow in sewer- or irrigational systems. We first provide the mathematical modeling, in particular with regard to multiple joints, and review results on wellposedness and controllabililty. We then look into constrained optimal control problems for such transportation networks and provide numerical evidence. We further discuss problems of homogenization of some linearized models on periodic subgraphs.

Compactly-supported solutions of Euler equations. **Camillo De Lellis** (Universität Zürich, Switzerland) IC/MT4311/046

In a recent joint work with Laszlo Szekelyhidi we apply techniques of differential inclusions to construct distributional solutions of the 2-d Euler equations which are compactly supported in space and time. Such examples were first given in a pioneering work of Scheffer and later on by Shnirelman with a different construction.

We improve these two results from several points of view. First of all, in their examples the velocity is L^2 in time and space, and hence it does not belong to the naturaly energy space, whereas our construction yields bounded velocity and bounded pressure. Second, our proof is much shorter and quite elementary. Finally, though at a first sight Shnirelman's and Scheffer's constructions seem quite different, our approach gives a bridge between them.

IC/MP682/046: Conservation laws with discontinuous flux.

Organiser: Raimund Bürger (Universidad de Concepción, Chile)
Co-organiser: Kenneth Karlsen (Universitetet i Oslo, Norway)

Conservation laws and related equations, such as degenerate parabolic equations, having a discontinuous flux appear in several mathematical models in the applied sciences and engineering, such as clarifier–thickener models, traffic flow and multiphase flow through heterogeneous porous media. They are equally of theoretical interest.

The basic mathematical problem is that the well-posedness of these equations does not emerge straightforwardly as a limit case of the standard entropy solution theory of conservation laws with a flux that depends continuously on the spatial variable. In particular, there is no unique concept of admissibility conditions a jump of the solution across a jump of the flux (with respect to the spatial variable) needs to satisfy. For example, in applications of two-phase flow through a heterogenous porous medium, undercompressive jumps are not admissible, while the nature of the flux discontinuity in a clarifier–thickener model compels them in many situations.

A recent trend in dealing with this problem is the adaptation of these admissibility conditions to the physics of the underlying model considered. Moreover, most admissibility concepts are supported by a provably convergent numerical scheme.

In this minisymposium, we intend to exchange the latest developments in the area of conservation laws with discontinuous flux, which has attracted recent interest and generated a considerable number of contributions from researchers worldwide.

The Dirichlet problem for scalar conservation laws with discontinuous fluxes in several space dimensions. **Julien Jimenez** (Université de Pau et des Pays de l'Adour, France), Laurent Levi (Université de Pau et des Pays de l'Adour, France) IC/MT3629/046

We carry out the mathematical analysis of a quasilinear first-order hyperbolic equation set in the hypercube $\Omega =]-1,1[^n$. The problem can be read as follows for any positive and finite T: Find $u \in L^\infty(]0,T[\times\Omega)$ such that

$$\begin{aligned} \frac{\partial u}{\partial t} + \mathrm{div}(\mathbf{B}(x)g(u)) + f(t,x,u) &= 0 \text{ in }]0,T[\times\Omega, \\ u(0,.) &= u_0 \text{ on } \Omega, \\ u &= 0 \text{ on (a part of) }]0,T[\times\partial\Omega, \end{aligned}$$

where the vector field $\mathbf{B} = (B_1, ..., B_n)$, is such that only one of its components, named B_k, is discontinuous across the fixed hyperplane $[x_i = 0]$. We first provide the definition of a weak entropy solution for this equation. As we suppose that the convection term is *genuinely nonlinear*, we can define strong traces of an entropy solution at left and right of $[x_i = 0]$. This way the uniqueness property is obtained through the method of doubling variables and thanks to a Rankine–Hugoniot condition along the discontinuity.

We investigate two methods in order to obtain an existence result. The first one is based on a regularization of the component B_k while in the second one, we consider a vanishing viscosity method that consists in studying the limit when ϵ goes to 0^+ of the sequence $(u_\epsilon)_{\epsilon>0}$ of solutions to the diffusion problems:

$$\begin{cases} \dfrac{\partial u_\epsilon}{\partial t} + \mathrm{div}(\mathbf{B}(x)g(u_\epsilon)) + f(t,x,u_\epsilon) = \epsilon\Delta u_\epsilon \text{ in }]0,T[\times\Omega, \\ u_\epsilon(0,.) = u_0 \text{ on } \Omega, \\ u_\epsilon = 0 \text{ on }]0,T[\times\partial\Omega. \end{cases}$$

These results can be extended when the discontinuity of B_k occurs along a hypersurface.

A Riemann solver approach for conservation laws with discontinuous flux. **Andrea Terracina** (Università degli Studi di Roma "La Sapienza", Italy) IC/MT3652/046

We consider an hyperbolic scalar conservation laws with discontinuous flux of the following type

$$u_t + \big(H(x)f(u) + (1-H(x))g(u)\big)_x = 0 \quad \text{in } \mathbb{R}\times(0,T), \quad u(x,0) = u_0(x) \text{ in } \mathbb{R}\times\{0\},$$

where $f(u)$ and $g(u)$ are regular and concave and H is the Heaviside function. There are different applications in which this problem arises. In particular we are motivated from considering a fluidodynamic description for traffic flow on a simple road network, composed by two roads connected together by a junction (see[4]). This kind of problem was studied in literature see for example [1]–[7]. In particular in [2] and in [7] are given different formulations that in general characterize different solutions for this problem.

In [1,5], using different techniques, it was proved that it is possible to consider infinite class of entropy solutions and for each of these there is stability in L^1 respect to initial data. More precisely in [5] we observe that a concept of solution is uniquely characterized if we decide how to solve the Riemann problem. In this sense we give a formulation for the problem depending on that Riemann solver assuming that almost everywhere the traces $(u(0-,\cdot), u(0+,\cdot))$ are in equilibrium respect to the Riemann solver.

Existence is proved by a front tracking algorithm that takes in account the Riemann solver at the point $x = 0$ (see also [4]). Given a sequence of approximate front tracking solutions $\{u_n\}$ the main difficulty is to establish *a priori* BV estimate for the functions $f(u_n(\cdot,t))$, $g(u_n(\cdot,t))$ and $f(u_n(0+,\cdot))$.

Semi-Godunov schemes for multi-phase flows in porous media. **Siddhartha Mishra** (Center of Mathematics for Appications, University, Norway), Kenneth Karlsen (Universitetet i Oslo, Norway), Nils Risebro (Universitetet i Oslo, Norway) IC/MT2698/046

In this talk, we consider three phase flows in porous media which arise while modeling petroleum reservoir simulation. The three phases are gas, oil and water. These models involve systems of two conservation laws which have a very complicated wave structure and are in general non-strictly hyperbolic. We design and implement finite volume schemes of the Godunov type which are based on a local decomposition of the system into a sequence of scalar conservation laws with discontinuous coefficients. These numerical schemes are very easy to implement and donot use the wave structure of the full system. Numerical examples illustrating the efficiency of the proposed method are presented.

A difference scheme for an inhomogeneous traffic model. **John Towers** (MiraCosta College, USA), Raimund Bürger (Universidad de Concepción, Chile), Kenneth Karlsen (Universitetet i Oslo, Norway) IC/MT2975/046

Our contribution discusses a simple finite difference scheme that we recently devised for kinematic flows modeled by conservation laws. We apply our scheme to a scalar conservation law modeling traffic flow on a highway. The flux has a discontinuous spatial parameter, which models for example a change in the number of lanes. We improve on our scheme by modifying it slightly at the interface where the jump occurs. This has the practical advantage of reducing or eliminating certain small spurious traveling waves that the original scheme produces. From a theoretical point of view, this modification implies that the scheme enforces a certain distinguished steady state solution. This allows one to prove that the limit of the scheme satisfies a so-called adapted entropy condition. We use this entropy condition to define a solution concept, and prove that our scheme generates approximations converging to such a solution.

On adaptive multiresolution methods for hyperbolic conservation laws. **Margarete Domingues** (Instituto Nacional de Pesquisas Espaciais, Brazil) IC/MT3637/046

Adaptive strategies in space and time allow considerable speed up of finite volume schemes for conservation laws, while controlling the accuracy of the discretization. In the present talk, we present multiresolution techniques for finite volume schemes with explicit time discretization. An adaptive grid is introduced by suitable thresholding of the wavelet coefficients, which maintains the accuracy of the finite volume scheme of the regular grid. The number of costly flux evaluations is significantly reduced, together with the memory requirement, thanks to dynamic tree data structure. Further, speed-up is obtained by local scale dependent time stepping, i.e. on large scales larger time steps can be used without violating the stability condition of the explicit scheme. Furthermore, an estimation of the truncation error in time, using a Runge-Kutta-Fehlberg scheme, guarantees a control of the time step for a given precision. The accuracy and efficieny of the fully adaptive method is illustrated with applications.

Fully-adaptive multi-resolution schemes for strongly-degenerate parabolic equations with discontinuous flux. **Mauricio Sepúlveda** (Universidad de Concepción, Chile), Raimund Bürger (Universidad de Concepción, Chile), Kai Schneider (Université de Provence Aix-Marseille I, France), Ricardo Ruiz Baier (Universidad de Concepción, Chile) IC/MT3361/046

A fully adaptative numerical scheme for one-dimensional strongly degenerate parabolic equations with discontinuous flux is presented. The numerical scheme is based on a finite volume discretization using the approximation of Engquist-Osher for the flux and explicit time stepping. An adaptative multiresolution scheme with cell averages is then used to speed up CPU time and memory requirements, and we derive an optimal choice of the threshold in the adaptative multiresolution method. Applications to mathematical models of flocculated suspensions in a clarifier-thickener and traffic flow with driver reaction illustrate the efficiency of this method.

Homogenization of two-phase porous-media flow with periodical heterogeneities. **Alexander Dressel** (Universität Stuttgart, Germany) IC/MT2917/046

The homogenization of periodical heterogenities in two-phase porous media flow is discussed, where water is injected into a porous medium with heterogeneous relative permeability. The flow is modelled as scalar conservation law with a Buckley-Leverett flux function having a discontinuous parameter. The analysis relies on appropriate energy estimates for the functional induced by the antiderivative of the discontinuous flux function in dependence of the spatial scale of capillarity and the microscale parameter.

Initial-data identification for conservation laws. **François James** (Université d'Orléans, France), Marie Postel (Université Pierre et Marie Curie, France) IC/MT3702/046

Identifying the initial data in a system of conservation laws is a major problem for instance in data assimilation. The problem can be formulated as the minimization of some cost function which compares the solution to some experimental observation. A natural idea is therefore to compute the gradient of the function, and this turns out to be very difficult when discontinuities are involved in the solution. Indeed the computations lead to linearize the original system, so that linear equations with discontinuous coefficients arise. In this talk, we shall on the one hand investigate the few available theoretical results in this direction, on the other hand present numerical strategies which give convenient results.

IC/MP418/046: Non-local conservation laws.

Organiser: Helge Holden (Norges Teknisk-Naturvitenskapelige Universitet, Norway)
Co-organiser: Kenneth Karlsen (Universitetet i Oslo, Norway)

In recent years nonlocal conservation laws have received a great deal of attention, both because they pose interesting mathematical and numerical problems and arise in a variety of different applications like shallow water waves, waves in compressible rods, radiating gases, and so forth. Typically, they take the form

$$u_t + uu_x + P_x = 0\,, \quad P = g \star h(u, u_x)\,, \quad t > 0\,,\ x \in \mathbb{R}\,,$$

where u denotes unknown function, g is a convolution kernel, often generated by the inverse of a differential operator, $\star$ denotes convolution in the spatial variable, and h is a given smooth function of u and u_x, typically linear or quadratic in its arguments. A frequently used example of a kernel g is $\frac{1}{2}e^{-|x|}$, which is the inverse of the operator $L = 1 - \partial_{xx}^2$, in which case the above equations takes the form of a hyperbolic–elliptic system:

$$u_t + uu_x + P_x = 0\,, \quad -P_{xx} + P = h(u, u_x)\,.$$

A few examples of nonlocal conservation laws are provided by the following list:

- Hunter–Saxton–Zheng equation:
$u_t + uu_x = \frac{1}{2}\int^x (u_x)^2 \mathrm{d}x$;
- Camassa–Holm equation:
$u_t + \gamma uu_x + P_x = 0\,, \quad -P_{xx} + P = \frac{1}{2}(3-\gamma)u^2 + \frac{1}{2}\gamma(u_x)^2$.
- Dai's rod equation: $u_t + \gamma uu_x + P_x = 0\,, \quad -P_{xx} + P = \frac{1}{2}(3-\gamma)u^2 + \frac{1}{2}\gamma(u_x)^2$.
- Degasperis–Procesi equation:
$u_t + uu_x + P_x = 0\,, \quad -P_{xx} + P = \frac{3}{2}u^2$.
- Burger–Poisson type model:
$u_t + uu_x + P_x = 0\,, \quad -P_{xx} + P = u$;
- RosenauŠs regularization model/radiating gas model: $u_t + uu_x + P_x = 0\,, \quad -P_{xx} + P = -u_x$.

Some of these equations (e.g., Camassa–Holm equation) possess truly remarkable properties such as an inifinite number of conserved integrals, a bi-Hamiltonian structure, and complete integrability, non-smooth solitary wave solutions, and wave breaking.

This session will present recent mathematical results (existence, uniqueness, stability, regularity, asymptotic/singular limit problems, etc.) on various types of nonlocal conservation laws. Additionally, the numerical treatment/analysis of these equations will be discussed. Finally, there will be presentation of examples where nonlocal conservation laws arise in the modelling of wave phenomena.

Initial boundary value problems for the Degasperis–Procesi equation. **Zhaoyang Yin** (Zhongshan University, PR China) IC/MT4699/046

This talk will address initial boundary value problems of the Degasperis–Procesi equation on the half line and on a compact interval. We first establish the local well-posedness for initial boundary value problems of the equation on the half line and on a compact interval, respectively. We then present some blow-up and global existence results for strong solutions. We finally investigate global and local weak solutions. One interesting result is that the corresponding strong solutions to the equation on the half line blow up in finite time provided the initial potential being negative is not identical with zero. The other one is that all global strong solutions to the equation on a compact interval blow up in finite time.

This work was done in collaboration with Joachim Escher and supported by the Alexander von Humboldt Foundation.

Non-local conservation laws for channel-porous media flow. **Steinar Evje** (Universitetet i Stavanger, Norway), Kenneth Karlsen (Universitetet i Oslo, Norway) IC/MT3801/046

We consider a mathematical model for fluid flow in a coupled channel-porous media system. The model is comprised of an integral equation representing unsteady 3-D porous media flow and the unsteady 1-D isothermal Euler equations representing flow in a channel-line. More precisely, the channel flow is described by the equations

$$\partial_t(A\rho_w) + \partial_s(A\rho_w u) = q_{\mathsf{M}}$$
$$\partial_t(A\rho_w u) + \partial_s(A\rho_w u^2) + A\partial_s p_w = q_{\mathsf{F}}, \qquad (s,t) \in [0, L_w] \times (0, T],$$

where s is position along the channel of length L_w and cross-sectional area A. $\rho_w(s,t)$ is fluid density, $u(s,t)$ fluid velocity, $p_w(s,t) = p(\rho_w(s,t))$ pressure, $q_{\mathsf{M}}(s,t)$ mass flow rate per unit wellbore length whereas $q_{\mathsf{F}}(s,t)$ represents frictional forces. The porous media flow may be described by the following integral representation

$$\rho_0(\mathbf{x}) - \rho(\mathbf{x}, t) = \int_0^t \int_0^{L_w} G(\mathbf{x}, \mathbf{X}_w(s'), t - t') q_{\mathsf{M}}(\mathbf{X}_w(s'), t') \|\mathbf{X}_w'(s')\|\, ds'dt',$$

where ρ_0 is initial density, $G(\mathbf{x}, \mathbf{X}_w(s'), t-t')$ is a kernel appropriate for porous media and $\mathbf{X}_w(s) = (x_w(s), y_w(s), z_w(s))$, $s \in [0, L_w]$ describes the channel-line. We are interested in simplified versions of this model that might shed light on some aspects of the full model. Particularly, we seek existence and uniqueness results, blow-up phenomena, and long-time behavior for these models.

Wave breaking in non-local dispersive wave equations. **Hailiang Liu** (Iowa State University, USA) IC/MT3852/046

The Korteweg–de Vries (KdV) equation is well known as an approximate model for small amplitude and long waves in different physical contexts, but wave breaking phenomena related to short wavelengths are not captured in. In this work we consider a class of nonlocal dispersive wave equations which also incorporates physics of short wavelength scales. The model is identified by a renormalization of an infinite dispersive differential operator, followed by further specifications in terms of conservation laws associated with the underlying equation. Several well-known models are thus rediscovered. Wave breaking criteria are obtained for several models including the Burgers-Poisson system, the Camassa-Holm type equation and an Euler-Poisson system. The wave breaking criteria for these models are shown to depend only on the negativity of the initial velocity slope relative to other global quantities.

Damping effects and nonlocal operators in radiation hydrodynamics. **Christian Rohde** (Universität Stuttgart, Germany) IC/MT4956/046

The dynamics of an inviscid radiating fluid can be described by the compressible equations of hydrodynamics coupled to an ensemble of linear transport equations for the direction dependent radiation intensity. Applications appear in astrophysics but also in down-to-earth problems like the simulation of flows in turbines. In these applications various limit regimes become important and give rise to consider a whole hierarchy of evolution equations. In particular the system depends on a parameter for the speed of light. Among others we consider the so-called nonrelativistic limit when this parameter tends to infinity. The limit regime is governed by a nonlinear but nonlocal conservation law. The existence of global weak solutions and -most notably- of classical solutions for small initial data is proven. We stress that solutions of standard nonlinear conservation laws develop shock singularities for general inital data. Finally we present numerical simulations for the limit conservation law which illustrates interesting radiation damping effects. This is joint work with Wen-An Yong and Nils Tiemann.

IC/MP272/047: Wave propagation in complex and random media.

Organiser: Peter Blomgren (San Diego State University, USA)

Over the last decade significant progress has been made in the theoretical understanding, numerical and simulation capabilities, as well as real-world applications of wavepropagation in complex/random media. Applications range from underwater acoustics, medical and industrial ultrasound, to electromagnetic imaging and communications using "smart antennas." In this minisymposium we focus on the state-of-the-art theory, simulations, and applications in the acoustic as well as electromagnetic regimes, with an emphasis on progress relating to time-reversal, imaging, communications and remote sensing.

Progress in computational wave propagation: simulated time-reversal and imaging in 3D random waveguides. **Peter Blomgren** (San Diego State University, USA) IC/MT2794/047

We quickly survey the development of computational wave propagation in random media during the last decade, and then focus on recent results of simulations in realistic size 3-dimensional wave guides where the propagation distance is in the hundreds or thousands of wavelengths. The recent computational studies are in the wireless (EM) regime, and we study the quality of communication in a multiple-in-single-out (MISO) TR-based communications system.

(Joint work with George Papanicolaou)

Propagation and detection in clutter. **Knut Solna** (University of California, Irvine, USA) IC/MT2814/047

We consider propagation in a cluttered environment. In the case with long range propagation and medium variations we discuss how the wave interacts with the medium. We also consider how scatterer detection performance is affected in such a noisy environment.

Pulse propagation and time reversal in random waveguides. **Josselin Garnier** (Université Paris VII, France) IC/MT1902/047

We consider pulse propagation in a random waveguide. We perform an asymptotic analysis based on separation of scales, when the propagation distance is large compared to the size of the random inhomogeneities, which have small variance, and when the typical wavelength is comparable to the scale of the inhomogeneities.

We study the asymptotic form of the joint distribution of the mode amplitudes at different frequencies. We derive from first principles an asymptotic deterministic system of time-frequency transport equations for the coupled mode amplitudes.

We apply the transport equations to study pulse spreading in a random waveguide and to show how randomness reduces time dispersion at the expense of having random fluctuations. We also apply them to analyze time-reversal in a random waveguide. We show that randomness enhances spatial refocusing and that diffraction-limited focal spots can be obtained even with small-size time reversal mirrors. However, statistical stability for narrowband refocused fields is achieved only for large-size time reversal mirrors. The mechanisms responsible for statistically stable refocusing in a random waveguide are clarified.

Work in collaboration with George Papanicolaou (Stanford University).

Direct-imaging algorithms for extended targets. **Hongkai Zhao** (University of California, Irvine, USA) IC/MT1630/047

I will present a few direct imaging algorithms for extended targets using both near and far field data. No forward problem or iterations are neended in our algorithms. Robustness with respect to both measurement noise and medium inhomogeneity will be shown. This is joint work with S. Hou, K. Huang, and K. Solna.

IC/MP272/047: Wave propagation in complex and random media. #2

Organiser: Peter Blomgren (San Diego State University, USA)

(For abstract, see session #1 above.)

Kinetic limits for wave equations in random media. **Lenya Ryzhik** (University of Chicago, USA) IC/MT2541/047

I will describe some of the results on the kinetic equations for the phase space wave energy density in random media. Such equations typically arise in the high frequency, long propagation distance limit. These results are a joint work with G. Bal and T. Komorowski.

Illumination design for imaging. **Chrysoula Tsogka** (University of Chicago, Greece) IC/MT2732/047

We consider array imaging in clutter with coherent interferometric techniques. We address the problem of optimal illumination and seek the input waveform using an optimality criterion that measures the quality of the resulting image. The robustness of the method is illustrated with several results.

This is joint work with Liliana Borcea and George Papanicolaou

Optimal waveform design for array imaging. **Liliana Borcea** (Rice University, USA) IC/MT2560/047

This talk is concerned with an inverse problem for the wave equation. More specifically, it considers coherent imaging of reflectors from measurements of the echoes at a remote array of transducers. The main question raised is how to design optimally the waveform used by the array to illuminate the reflectors, so that the image has the best resolution.

Imaging in random media. **George Papanicolaou** (Stanford University, USA) IC/MT3206/047

I will present a brief overview of array imaging methods when the medium between the object to be imaged and the array that is collecting the data is a random medium. This means that it is not known in detail but only statistically and through the array data. Imaging the object of interest cannot be done without some estimation of the properties of the random medium. What properties should be estimated and how? I will address this question and give some answers based on recent work on adaptive coherent interferometry done jointly with L. Borcea and C. Tsogka.

IC/MP308/047: Homogenization, inverse problems, and shape optimization.

Organiser: Eric Bonnetier (Université Grenoble I, France)
Co-organiser: Elena Cherkaev (University of Utah, USA)

Recent developments in homogenization, multiscale analysis, inverse problems, imaging of microstructured media, and shape optimization reveals that these fields share several fundamental concepts. For instance, asymptotic techniques in non-homogeneous media have fostered stable reconstruction algorithms in inverse problems. Similar asymptotics have led to new iterative methods in shape optimization. Homogenization results allowed to develop approaches to inverse or dehomogenization problems for materials with microstructure.

The minisymposium will focus on the interaction of ideas stemming from these areas.

Electrical impedance tomography with resistor networks. **Fernando Guevara Vasquez** (Stanford University, USA), Liliana Borcea (Rice University, USA), Vladimir Druskin (Schlumberger Ltd., USA) IC/MT1803/047

Electric impedance tomography consists in finding the conductivity inside a body from electrical measurements taken at its surface. This is a severely ill-posed problem: any numerical inversion scheme requires some form of regularization. We present inversion schemes that address the instability of the problem with a reduced model approach, where the reduced models are resistor networks that arise in the finite volumes discretization of the forward problem. Specifically, we consider finite volume grids of size determined by the measurement precision, but where the node locations are determined adaptively. We show that the model reduction problem of finding the smallest resistor network (of fixed topology) that can predict measurements of the Dirichlet-to-Neumann map is uniquely solvable for a broad class of measurements. We view the model reduction as a nonlinear map of the data. Numerical evidence suggests this map acts as an approximate inverse of the forward map. To image the conductivity we use this map as a preconditioner in a Newton type iteration. A priori information can be easily incorporated to the method.

On combining model reduction and Gauss–Newton algorithms. **Vladimir Druskin** (Schlumberger Ltd., USA), Mikhail Zaslavsky (Schlumberger Ltd., USA) IC/MT1605/047

We suggest an approach to speed up the Gauss-Newton solution of inverse PDE problems by minimizing the number of forward problem calls. The acceleration is based on effective incorporation of the information from the previous iteration via a reduced order model (ROM). It is designed with the help of Galerkin and pseudo-Galerkin methods for self-adjoint and complex symmetric problems respectively. The constructed ROM generates effective multivariate rational interpolation matching the forward solutions and the Jacobians from the previous iterations. Numerical examples for the inverse conductivity problem for the 3D Maxwell system show significant accelerations.

G-convergence and homogenization of a model of two-phase viscoelastic flows. **Alexander Panchenko** (Washington State University, USA) IC/MT2523/047

We study the system of balance equations modeling the flow of a two-phase, Kelvin–Voight viscoelastic material. We consider a sequence of highly oscillatory initial data, parametrized by a small parameter ε. The initial geometry is generic in the sense that periodicity or even random homogeneity are not assumed. Using G-convergence and oscillating test functions, we pass to the limit $\varepsilon \to 0$ and obtain an effective system of equations. These equations model a one-phase viscoelastic flow. The mass balance equation and convective terms in the momentum balance equation have the standard structure. The constitutive equation for effective stress contains a long memory term which is not present in the ε-problems.

Structural information of strongly heterogeneous two-component composites. **Christian Engstrom** (Universität Karlsruhe, Germany) IC/MT4993/047

For strongly heterogeneous two-component composites we address the inverse problem of estimating microstructural parameters from permittivity measurements. The dependence on the geometrical structure is reduced to the problem of calculating the moments of the measure in an integral representation of the effective permittivity. We present a method that uses measurement data at a set of distinct frequencies to calculated bounds on several moments, such as the volume fraction and the anisotropy of a composite. We show that this inverse homogenization method can be used even with a low number of data points and in the cases when the accuracy in the measurements is low. Furthermore, we use the microstructural information to tighten error bars on measurement data.

IC/MP308/047: Homogenization, inverse problems, and shape optimization. #2

Organiser: Eric Bonnetier (Université Grenoble I, France)
Co-organiser: Elena Cherkaev (University of Utah, USA)

(For abstract, see session #1 above.)

Inverse homogenization: can one hear the structure of composite materials?. **Elena Cherkaev** (University of Utah, USA) IC/MT2547/047

Inverse homogenization is a problem of deriving information about the microgeometry of composite material from its effective properties. The approach is based on reconstruction of the spectral measure in the analytic Stieltjes representation of the effective tensor of two-component composite. This representation relates the n-point correlation functions of the microstructure to the moments of the spectral measure, which contains all information about the microgeometry. The problem of identification of the spectral function from effective measurements in an interval of frequency has a unique solution, however the problem is ill-posed. The talk discusses several stabilization techniques as well as Pade approximations used to reconstruct the spectral function. Results of reconstruction of microstructural parameters are shown for visco-elastic composites and for composites of two materials with different complex permittivity. The reconstructed spectral function can be used to compute other effective parameters of the same composite; this gives solution to the problem of coupling of different effective properties of a two-component random mixture.

On de-homogenization of poroelastic materials . **Miao-jung Ou** (University of Central Florida, USA) IC/MT2818/047

In this talk, we present a de-homogenization scheme for inversion of microstructural informations from measurement data of effective stiffness moduli of a poroelastic composite with a band acoustic frequencies. The scheme is based on the integral representation formula which was first derived by Kantor & Bergman and further generalized by Ou & Cherkaev.

Periodic homogenization in Fourier space. **Niklas Wellander** (Swedish Defence Research Agency, Sweden) IC/MT2426/047

A two-scale Fourier transform for periodic homogenization in Fourier space is introduced. For any function f in $L^1(\mathbb{R}^n)$ and $\varepsilon > 0$ the *two-scale Fourier transform at the ε-scale* of f is defined by

$$\mathcal{F}_\varepsilon\{f\}(\xi, m) = \hat{f}_\varepsilon(\xi, m) = \int_{\mathbb{R}^n} f(x) e^{-2\pi i x\cdot\left(\xi+\frac{m}{\varepsilon}\right)} \mathrm{d}x\,,$$

for all $\xi \in \mathbb{R}^n, m \in \mathbb{Z}^n$. The corresponding inverse transform is given by

$$\mathcal{F}_\varepsilon^{-1}\{\hat{f}_\varepsilon\}(x) = \sum_{m\in\mathbb{Z}^n} \int_{\xi\in[-\frac{1}{2\varepsilon},\frac{1}{2\varepsilon}]^n} \hat{f}_\varepsilon(\xi, m) e^{2\pi i x\cdot\left(\xi+\frac{m}{\varepsilon}\right)} \mathrm{d}\xi\,.$$

The transform is applied to a standard periodic homogenization problem for homogenization in Fourier space. The transform is also used to define a two-scale transform (sometimes called periodic unfolding) and to Floquet–Bloch decompose differential operators.

The polarization tensor for irregular perfectly conducting inclusions. **Frédéric de Gournay** (Université de Versailles, France) IC/MT3322/047

We study how perturbations of the domain interferes with the solution of the Laplace equation with Dirichlet boundary conditions. The perturbations, in finite number, are allowed to be quite irregular. They may be of two kinds: Either they are a sequence of holes whose diameter (say smaller than ϵ) goes to zero. Or, they are perturbations of C^∞ holes, with the restriction that the pertubed holes contain the unperturbed ones, and that the distance between perturbed and unperturbed boundaries is smaller than ϵ. We show that the solution of the Laplace equation is differentiable with respect to ϵ in a weak sense. This work extends several cases of derivation with respect to the domain: the approach of Vogelius and Capdeboscq (who studied holes filled with weak material), the topological gradient (or bubble method) valid only for regular holes, and shape derivation techniques that are only valid for regular transport of a hole. Our method is based on energy estimates and therefore, may be quite easily extended to other elliptic operators.

IC/MP322/047: Nonlinear PDE techniques in imaging.

Organiser: Martin Burger (Universität Münster, Germany)
Co-organiser: Antonin Chambolle (École Polytechnique, France)

Imaging is a field of growing interest due to various important applications (e.g., in medicine and industry), which poses a lot of extremely challenging questions to applied and computational mathematics. Whereas linear filtering and PDE methods were and still are strongly for various tasks in imaging, there is a strong trend towards nonlinear PDE techniques nowadays, due to their superior capabilities to handle these tasks (such as segmentation, motion estimation, inpainting and even denoising). Celebrated examples of nonlinear PDE techniques are Perona–Malik filters and methods based on total variation and curvature.

The aim of this mini-symposium is to give a presentation of modern nonlinear PDE techniques (including second- and fourth-order PDE approaches) for several different tasks from several different perspectives. It includes speakers focusing on analysis, modelling, and computation, to highlight all of the different aspects. Moreover, two speakers are applied computer scientists bringing in an even more applied perspective of PDE techniques in imaging.

Non-linear regularization of irregular sampling problems in digital imaging. **Andrés Almansa** (Ecole Normale Supérieure de Cachan, France), Vicent Caselles (Universitat Pompeu Fabra, Spain), Gabriele Facciolo (Universitat Pompeu Fabra, Spain), Gloria Haro (University of Minnesota, USA), Bernard Rougé (Centre National d'Etudes Spatiales, France) IC/MT2368/047

We propose several algorithms to solve a problem in image restoration which considers several different aspects of it, namely: irregular sampling, denoising, deconvolution, and zooming. The first algorithm is based on an extension of a previous image denoising algorithm proposed by A. Chambolle using total variation, combined with irregular to regular sampling algorithms proposed by H.G. Feichtinger, K. Gröchenig, M. Rauth and T. Strohmer, and local constraints ideas from V. Caselles et. al. Then a few variants of total variation regularization, local constraints, and discretization techniques are considered in order further reduce the computational cost of the algorithm while at the same time better controling artifacts in coarsely sampled areas. Finally we present some experimental results and we compare them with those obtained with the algorithm proposed by K. Gröchenig et al.

How to discretize the total variation of an image?. **Lionel Moisan** (Universite Rene Descartes, Paris, France) IC/MT2790/047

The Total Variation (TV) has been introduced in the context of image restoration by Rudin, Osher and Fatemi 15 years ago as a Tikhonov-like regularization term more suitable to images than the classical H^1 norm. Since then, it has been used in many domains of image processing and analysis, including deblurring, blind deconvolution, zoom, inpainting, etc. Still recently it received a lot of attention both as the first component of Meyer's $u + v$ decomposition (and all following work), and because of the discover of new dual-based minimization algorithms (Carter, Chan-Golub-Mulet, Chambolle, ...). In this talk we study and compare possible discretizations of the total variation, and we show that finite differences are not very efficient, especially for small scales (pixel and sub-pixel scales). We then propose a new Fourier-based estimate (called spectral TV) that behaves much better in terms of grid invariance, isotropy, artifact removal, and sub-pixel accuracy, both as an estimate of the exact continuous TV and and as a control term (i.e. regularization term) for energy-minimization models based on TV minimization. We illustrate these properties with experiments, showing that the spectral TV significantly improves the quality of the results.

Solving the Chan–Vese model by a multi-phase level-set algorithm based on the topological derivative. **Lin He** (RICAM Linz, Austria), Stanley Osher (University of California, Los Angeles, USA) IC/MT4092/047

In this work, we specifically solve the Chan–Vese active contour model by multiphase level-set methods. We first develop a fast algorithm based on calculating the variational energy of the Chan–Vese model without the length term. We check whether the energy decreases or not when we move a point to another segmented region. Then we draw a connection between this algorithm and the topological derivative, a concept emerged from the shape optimization field. Furthermore, to include the length term of the Chan–Vese model, we apply a preprocessing step on the image by using nonlinear diffusion. We show numerical experiments to demonstrate the efficiency and the robustness of our algorithm.

PDEs in medical image reconstruction. **Frank Wuebbeling** (Universität Münster, Germany) IC/MT4185/047

While integral geometry techniques used to be the dominant tool in medical image reconstructions (in particular, in computed and emission tomography) in past years, the need for higher-precision and lower-dose modalities more and more require PDE methods which are capable of modeling the underlying physical processes more accurately.

Some examples include ultrasound tomography (governed by the Helmholtz equation in frequency domain or the wave equation in time domain), optical tomography (governed by the transport or diffusion equation, depending on the type of the underlying material, both in time and frequency domain) or high-precision Positron Emission Tomography (governed by the transport equation, taking scatter into account). Although the differential equations in these problems are linear, they usually lead to nonlinear inverse problems for a material parameter since coefficients and solutions to the PDEs both depend on the parameter, thus leading to large systems of bilinear equations.

Transferring the established ART-scheme from classical tomography to these non-(bi-)linear equations, we develop nonlinear ART, an adjoint method for the solution of nonlinear equations. Ultrasound tomography serves as an example for how this can be implemented in a very efficient way.

The method is applied to the modalities above, several examples are shown.

IC/MP322/047: Nonlinear PDE techniques in imaging. #2

Organiser: Martin Burger (Universität Münster, Germany)
Co-organiser: Antonin Chambolle (École Polytechnique, France)

(For abstract, see session #1 above.)

Mathematical aspects of the total variation approach to image restoration. **Vicent Caselles** (Universitat Pompeu Fabra, Spain) IC/MT1416/047

Image restoration (deconvolution and denoising) is an ill-posed problem usually solved with a regularization method. The use of total variation as a regularizing term was proposed by L. Rudin, S. Osher and E. Fatemi in 1992. In this model, to restore an image, one minimizes total variation under the constraints imposed by the image acquisition model. The corresponding Euler-Lagrange equation is a singular elliptic PDE involving the 1-Laplace operator. We study this PDE and its explicit solutions which lead to a series of geometric problems related to the characterization of calibrable sets. We interpret these results in terms of $u + v$ image decompositions in the sense of Yves Meyer. We also discuss the problem of image restoration in the case of irregularly sampled data.

Topological and variational properties of a model for the reconstruction of three-dimensional transparent images with self-occlusions. **Giovanni Bellettini** (Dipartimento di Matematica, Universita' di Roma To, Italy) IC/MT1593/047

We introduce and study a two-dimensional model for the reconstruction of a smooth generic three-dimensional scene E, which may handle the self-occlusions and that can be considered as an improvement of the 2.1D sketch of Nitzberg and Mumford. We characterize from the topological viewpoint the apparent contour of E, namely, we characterize those planar graphs G that are apparent contours of some scene E. Moreover, we show that if E and F are two of these scenes, then E and F differ by a global homeomorphism which is strictly increasing on each fiber along the direction of the eye of the observer. These two topological theorems allow to find the domain of the functional $\mathcal{F}$ describing the model. Compactness, semicontinuity and relaxation properties of $\mathcal{F}$ are then studied, as well as connections of our model with the problem of completion of hidden contours.

Work made in collaboration with V. Beorchia (Dipartimento di Matematica e Informatica, Università di Trieste, via Valerio 12/b, 34127 Trieste, Italy, E-mail: beorchia@units.it) and M. Paolini (Dipartimento di Matematica, Università Cattolica "Sacro Cuore", via Trieste 17, 25121 Brescia, Italy E-mail: paolini@dmf.unicatt.it).

Statistical shape influence in level-set segmentation. **Daniel Cremers** (Universität Bonn, Germany) IC/MT1654/047

Level-set methods have been developed to optimally partition a given image based on various assumptions about the intensity, color texture or motion of objects of interest. Nevertheless, most applications provide suboptimal segmentation results, as soon as these assumptions are not fulfilled – in particular if the input images are corrupted by noise, background clutter or partial occlusions of the objects of interest. In such cases, the segmentation results can be drastically improved by introducing prior shape knowledge into the segmentation process. I will present recent advances regarding the modeling of shape dissimilarity measures and their introduction into the segmentation process on a variational level. In particular, I will discuss the concept of *intrinsic alignment* to obtain invariance to certain group transformations, the concept of *dynamic labeling* to model the introduction of multiple competing shape priors, and the concept of *dynamical shape priors* which allows to statistically learn and impose information about temporal evolutions of implicit shapes. Respective parts of this work are based on collaborations with Nir Sochen, Christoph Schnoerr, Stanley Osher and Stefano Soatto.

A generalization of Cahn–Hilliard inpainting for gray-value images. **Carola-Bibiane Schönlieb** (Universität Wien, Austria), Martin Burger (Universität Münster, Germany) IC/MT1680/047

The Cahn-Hilliard equation has its origin in material sciences and serves as a model for phase separation and phase coarsening in binary alloys. A new approach in the class of fourth order inpainting algorithms is inpainting of binary images using the Cahn-Hilliard equation proposed in [1]. In this talk I will present a generalization of this fourth order approach for grayvalue images. This is realized by using subgradients of the total variation functional within the flow, which leads to structure inpainting with smooth curvature of level sets. I will present some numerical examples for this approach and analytic results concerning existence and convergence of solutions.

IC/MP254/047: **Image processing based on partial differential equations.**

Organiser: Antonio Marquina (Departamento Matematica Aplicada, Universidad de, Spain)
Co-organiser: Xue-Cheg Tai (Universitetet i Bergen, Norway)

PDE methods in image processing have experienced an impressive growth along the last fifteen years as a consequence to the advances in technology of imaging. Those methods have been applied to several important problems like image restoration, segmentation, inpainting, registration, surface construction,... The purpose of this minisymposium is to present and discuss recent advances and various aspects of new developments in using numerical techniques for partial differential equations to analyze and process digital images.

High-order geometric motion of an interface induced by diffusing distance functions. **Yen-Hsi Tsai** (University of Texas at Austin, USA) IC/MT3358/047

We propose a stable and efficient algorithm that iterates the steps of obtaining short time solutions of a linear PDE and nonlinear operations that involve redistancing (distance reinitialization) in order to achieve high order geometric motions of an interface. Traditional threshold dynamic approaches typically require large kernel size for the high order motions of interest and are not suitable for grid based computations. In this talk, we show the derivation of our algorithm and discuss the consistency, stability, and implementation of this algorithm.

This is joint work with Selim Esedoglu and Steven Ruuth.

A comparison of total variation *optimization algorithms.* **Jérôme Darbon** (University of California, Los Angeles, USA), Sylvain Lefebvre (INRIA Rocquencourt, USA), Tony Chan (National Science Foundation, USA), Selim Esedoglu (University of Michigan, Ann Arbor, USA) IC/MT3696/047

This study copes with the comparison of some Total Variation (TV) optimization algorithms. It includes an Euler–Lagrange based algorithm, the dual approach of Chambolle and finally a graph-cut (i.e., a combinatorial) based one. So far the last one is the known as the fastest. The main interest of this work is that the Euler–Lagrange algorithm is also implemented on a Graphic Processor Unit (GPU). Using this GPU architecture, it is shown that the Euler-Lagrange version is a serious competitor to the graph-cut based one. Finally some deep theoretical links between graph-cuts and TV optimization are shown.

Level-set methods for watershed image segmentation. **Erlend Hodneland** (Universitetet i Bergen, Norway) IC/MT3440/047

In this study a marker-controlled and regularized watershed segmentation is proposed. Only a few previous studies address the task of regularizing the obtained watershed lines from the traditional marker-controlled watershed segmentation. In the present formulation, the topographical distance function is applied in a level set formulation to perform the segmentation, and the regularization is easily accomplished by regularizing the level set functions. Based on the well-known Four-Color theorem, a mathematical model is developed for the proposed ideas. With this model, it is possible to segment any 2D image with arbitrary number of phases with as few as one or two level set functions. The algorithm has been tested on real 2D fluorescence microscopy images displaying rat cancer cells, and the algorithm has also been compared to a standard watershed segmentation as it is implemented in MATLAB. For a fixed set of markers and a fixed set of challenging images, the comparison of these two methods shows that the present level set formulation performs better than a standard watershed segmentation.

A time-evolution model for total-variation-based blind deconvolution. **Antonio Marquina** (Departamento Matematica Aplicada, Universidad de, Spain) IC/MT1976/047

In this research work we study a model for blind deconvolution based on the minimization of the total variation functional ([5],[2],[3]) combined with the Bregman iterative refinement procedure. The Bregman iterative refinement procedure is a technique used to recover finer scales in total variation based image restoration methods, ([1],[4]). The model is written as a system of PDEs evolving in time the signal and the estimated kernel, integrating implicitely the Bregman iteration in the whole process. We propose an explicit scheme that recovers edges and textures from a blurry and noisy signal. Nu-

merical tests indicate that the iterative procedure is stable and converges very fast to the restored images from initial images convolved with Gaussian blur and contaminated with Gaussian white noise.

Iteratively solving linear inverse problems under general convex constraints. **Luminita Vese** (University of California, Los Angeles, USA), Ingrid Daubechies (Princeton University, USA), Gerd Teschke (Zuse-Institut Berlin, Germany) IC/MT3074/047

We consider linear inverse problems where the solution is assumed to fulfill some general homogeneous convex constraint. We develop an algorithm that amounts to a projected Landweber iteration and that provides and iterative approach to the solution of this inverse problem. For relatively moderate assumptions on the constraint we can always prove weak convergence of the iterative scheme. In certain cases, i.e. for special families of convex constraints, weak convergence implies norm convergence. The presented approach covers a wide range of problems, e.g. Besov- or BV-restoration for which we present also numerical experiments in the context of image processing.

PDE methods for identifying ischemic heart disease. **Marius Lysaker** (Simula Research Laboratory, Norway), Bjørn Nielsen (Simula Research Laboratory, Norway) IC/MT3727/047

We explore the possibilities for using high speed laptops, mathematics and biological knowledge to construct a new medical imaging device. The source of the electrical potentials measured in ECG recordings at the body surface is the electrical pulses generated by the myocardium (heart). Our goal is to use ECG data and a geometrical model of the human body to compute an image of the potential distribution inside the heart wall. Since many heart conditions lead to changes in the potential pattern, such a device could be very useful for the physician.

Image inpainting and noise removal using the TV-Stokes equation. **Xue-Cheg Tai** (Universitetet i Bergen, Norway) IC/MT3438/047

In this talk, we propose a two-step algorithm for denoising digital images with additive noise and for inpainting of digital images. Observing that the isophote directions of an image correspond to an incompressible velocity field, we impose the constraint of zero divergence on the tangential field. Combined with an energy minimization problem corresponding to the smoothing of tangential vectors, this constraint gives rise to a nonlinear Stokes equation where the nonlinearity is in the viscosity function. Once the isophote directions are found, an image is reconstructed that fits those directions by solving another nonlinear partial differential equation. In both steps, we use finite difference schemes to solve. We present several numerical examples to show the effectiveness of our approach.

This talk is based on joint works with Stanley Osher and Talal Rahman.

IC/MP1/047: Non-standard and problem-oriented regularization methods.

Organiser: Sergei Pereverzyev (RICAM Linz, Austria)

Modern regularization theory has developed a general regularization scheme providing a uniform approach to the numerical treatment of ill-posed inverse problems. This general scheme includes such well-known regularization methods as Tikhonov and Lavrentiev regularization, Landweber iteration and others. At the same time, there exist regularization methods which use specific features of individual problems and, for this reason, can be applied only to them. The simplest example is a finite-difference scheme for numerical differentiation (classical ill-posed problem). Another important example is the quasi-reversibility method proposed by Lattes and Lions (1967) for solving the Cauchy problem for Laplace equation (one more classical ill-posed problem). Formally this method can be viewed as Tikhonov regularization, but a general theory cannot be used for its theoretical justification, because corresponding operator is unbounded. Other examples of methods falling into above mentioned category are the Method of lines proposed by Elden for the sideways heat equation, Local regularization methods for the solution of Volterra problems investigated by Lamm, Natural linearization method developed by Engl et al. for the parameter identification in nonlinear parabolic system, Regularization by Variance Components for geopotential determination from satellite data, and various forms of Regularization by discretization. Computational practice shows that such problem oriented methods are potentially very efficient, but they are not covered by a general theory and, as a result, some important questions related with their justification are still open. The goal of the Minisymposium is to bring together the experts, which have made recent contributions to the topic, with the aim to discuss a state of art and to elaborate a common platform for the development and implementation of Problem Oriented Regularization Methods.

Solving ill-posed Cauchy problems using regularization by discretization. **Lars Eldén** (Linköpings universitet, Sweden) IC/MT574/047

Sideways parabolic equations and the Cauchy problem for elliptic equations are examples of ill-posed Cauchy problems for PDE's. Such a problem can be written formally as an initial value problem

$$u_x = P(u), \qquad u(x_0) = u_0,$$

where the partial differential operator P is unbounded. Often the problem can be regularized by approximating the unbounded operator by a discretization, using e.g. wavelets or spectral methods. Stability results can be obtained.

We give a couple of examples of such problems, and describe how the discrete problems can be solved efficiently.

On the balancing principle for some problems of numerical analysis. **Shuai Lu** (RICAM Linz, Austria), Sergei Pereverzyev (RICAM Linz, Austria) IC/MT746/047

We discuss a choice of weight in penalization methods. The motivation for the use of penalization in computational mathematics is to improve the conditioning of the numerical solution. One example of such improvement is a regularization, where a penalization substitutes an ill-posed problem for a well-posed one. In modern numerical methods for PDEs a penalization is used, for example, to enforce a continuity of an approximate solution on non-matching grids. A choice of penalty weight should provide a balance between error components related with convergence and stability, which are usually unknown. In this paper we propose and analyze a simple adaptive strategy for the choice of penalty weight which does not rely on *a priori* estimates of above mentioned components. It is shown that under natural assumptions the accuracy provided by our adaptive strategy is worse only by a constant factor than one could achieve in the case of known stability and convergence rates. Finally, we successfully apply our strategy for self-regularization of Volterra-type severely ill-posed problems, such as the sideways heat equation, and for the choice of a weight in interior penalty discontinuous approximation on non-matching grids. Numerical experiments on a series of model problems support theoretical results. (Joint work with Prof. Raytcho D. Lazarov, Department of Mathematics, Texas A&M University)

The method of quasi-reversibility to solve the Cauchy problem for elliptic PDEs. **Laurent Bourgeois** (ENSTA, France), Eric Luneville (ENSTA, France) IC/MT951/047

This talk is devoted to the method of quasi-reversibility to solve ill-posed elliptic PDEs, which was first introduced in the late 60s by R. Lattès and J.-L. Lions. We first revisit the method in the general context of Tikhonov regularization of bounded or unbounded operators. Secondly, we apply the Morozov's discrepancy principle to it in order to make a relevant choice of the regularization parameter, and emphasize the interpretation of this choice in term of duality in optimization. Lastly, we show some numerical computations of the method of quasi-reversibility and of the associated Morozov's choice with the duality technique. These computations use nonconforming finite elements. Some error estimates are also presented.

Identification of parameters in nonlinear time-dependent PDEs via a multiharmonic ansatz. **Barbara Kaltenbacher** (Universität Stuttgart, Germany) IC/MT960/047

The problem of identifying coefficient functions in nonlinear time dependent PDEs from boundary measurements over some time interval, as arising e.g., in material characterization, is in practice often considered in frequency rather than in time domain. Here, it turns our that often a moderate number of higher harmonics suffices to describe the system with sufficient accuracy. Motivated by this fact, we propose a parameter identification method that is based on a multiharmonic expansion of the field quantities governed by the time dependent PDE under consideration. It turns out that an approximation of the coefficient function as a polynomial leads to a system of nonlinear but only space dependent PDEs. The (approximate) inverse problem then amounts to identifying polynomial coefficients appearing within this system, from additional boundary data. Regularization of the originally ill-posed problem of parameter identification is here achieved by finite dimensional projection (using the self-regularizing properties of discretization) as well as early stopping of the Newton iteration used for recovering the polynomial coefficients. In this talk we will explain the proposed method, provide some analysis and show numerical results.

Regularization for gravitational-potential determination from space. **Juergen Kusche** (GFZ Potsdam, Germany), Jasper van Loon (TU Delft, The Netherlands) IC/MT978/047

The *decade of the geopotentials*, which had started with the launch of the CHAMP (Challenging Minisatellite Payload for Geophysical Application) satellite on July 15, 2000, has brought completely new data sets to the geodetic and geophysical communities, and initiated the development of new methodologies in the recovery of the Earth's gravitational and magnetic potentials from spaceborne measurements. Historically, the determination of the Earth's outer gravitational potential and the geoid - an equipotential surface coinciding with mean sea level - was undertaken from collecting huge quantities of surface, ship- and airborne gravity measurements by solving a free boundary-value problem, or alternatively from orbit perturbations of passive satellites or altimetric measurements of sea-surface heights. But with the CHAMP and successive GRACE spaceborne data sets we now have observations of unprecedented homogeneity and accuracy that allow today to determine and understand even the tiny temporal changes in the Earth's gravitational field caused by groundwater changes in larger reservoirs and non-steric sea-level variations.

Whereas the observation of the Earth's gravitational field from space has many advantages, it essentially poses an ill-posed problem because we need to perform downward continuation, because we have to deal with noisy discrete data of complicated correlation structure taken at different altitudes, and because of data gaps caused by insufficient satellite coverage. In geodesy, since the begin of the space age problem- oriented regularization methods have been developed: the expansion of the potential into truncated spherical harmonic series, the so-called Kaula method of regularization by introducing prior information, the collection of complementary data to fill data gaps, or the application of post-processing filter techniques to smooth the potentials. More recent studies have been looking into the applicability of Tikhonov-type and iterative regularization methods and parameter-choice strategies well-known in the inverse problems community, including regularization by estimating variance components, robust estimation methods,

and the construction of nonisotropic post-analysis filters. The talk will provide an overview on recent concepts and developments

On gradient methods for maximum entropy regularizing retrieval of atmospheric aerosol particle size distribution function. **Yanfei Wang** (Chinese Academy of Sciences) IC/MT987/047

The determination of the aerosol particle size distribution function using the particle spectrum extinction equation is an ill-posed integral equation of the first kind [1]. Even for finite moment case, the problem is still discrete ill-posed, since as is known, we are often faced with limited /insufficient observations in remote sensing and the observations are contaminated. To overcome the ill-posedness, regularization techniques are developed. However, most of the literature focuses on the application of Phillips-Twomey's regularization or its variants which is unstable in several cases. Recently in [2], the authors considered Tikhonov's smooth regularization method in $W^{1,2}$ space for ill-posed inversion. But the method still relies on the choice of the regularization parameter and the *a priori* estimation of the noise level. As is known, the particle size distribution is always positive and we are often faced with incomplete data. The concept of maximum entropy from information theory and statistic mechanics can be best used for this purpose. Therefore, in this paper, we study the maximum entropy based regularization method and develop a gradient method for solving the corresponding optimization problem. Our numerical tests are based on the remotely sensed data by CE 318 for Po Yang lake region of Jiang Xi Province which is a specified typical area by national 973 project, and are performed to show the efficiency and feasibility of the proposed algorithms.

Local regularization for ill-posed Volterra inverse problems. **Patricia Lamm** (Michigan State University, USA) IC/MT1175/047

We will discuss recent developments in the theory and application of local regularization for ill-posed Volterra inverse problems. In particular, we will discuss extensions of the theory to allow for fast sequential solution of nonlinear equations as well as a discrepancy principle to select the size of the local regularization interval and qualitative properties of the measure used in the regularization process.

Landweber–Kaczmarz methods for regularizing systems of nonlinear ill-posed equations. **Antonio Leitao** (Universidade Federal de Santa Catarina, Brazil), Markus Haltmeier (Universität Innsbruck, Austria) IC/MT4281/047

In this talk we develop and analyze novel iterative regularization techniques for the solution of systems of nonlinear ill-posed operator equations. The basic idea consists in considering separately each equation of this system and incorporating a loping strategy. The first technique is a Landweber-Kaczmarz-type method, equipped with a novel stopping criteria. The second method is obtained using an embedding strategy, and again a Kaczmarz-type approach. We prove well-posedness, stability and convergence of both methods.

IC/MP147/047: Inverse and ill-posed problems in industry.

Organiser: Yanbo Wang (Fudan University, PR China)

This minisymposia is to bring together the people who are interested in the inverse and ill-posed problems in industry. The four speakers are experts in this field. They will present their new ideas and new results on this topic. The audiences can know the new development in this field. I think it will be very interesting for the audiences to have this chance to meet together in this minisymposia.

The impact of the noise-covariance structure upon the accuracy of indirect estimation. **Sergei Pereverzyev** (RICAM Linz, Austria) IC/MT425/047

The question addressed in the talk is: "How can colored observation noise be taken into account properly without direct access to a noise covariance operator?" Discussing inverse estimation from noisy observations it is reasonable to distinguish global and local regularization. Within a global regularization one tries to recover the whole solution as an element of some normed space. In local regularization the goal is to specify only some details such as a point value, or a wavelet/Fourier coefficient. We will show that in principle random colored noise allows us to obtain a better accuracy of a local regularization than deterministic noise.

For global regularization the situation is opposite: random colored noise will not *help* us to recover the whole solution. It gives a hint that optimal local regularization can be used as a *referee* for a global regularization in a sense that some global regularization strategy can be accepted if approximate solution, it provides, has point values or wavelet/Fourier coefficients which are close to ones estimated within the local regularization.

The talk is based on the results of a joint research with Frank Bauer and Peter Mathe.

How is a hidden rule found from operation data?. **Junichi Nakagawa** (Gakushuin University, Japan) IC/MT1799/047

Steel company researchers tend to focus on manufacturing processes. The phenomena are mostly complex, however, observations are limited because we must operate with high temperature objects and large-scale equipment. Consequently, we have been trying to find hidden rules from operation data. Supposed we show a map representing the position of these phenomena in four categories of the manufacturing process: stationary, non-stationary, linear and nonlinear, our phenomena fall into the non-stationary and nonlinear category. However, we donŠt have a general method by which this area can be analyzed. If mathematical principals can be applied in this area, we can have direct linkage between real phenomena and mathematics. Inverse problem is important to find hidden phenomena on manufacturing process from limited observation data. We show several examples of inverse analysis. These will enable reduced costs, and innovation in manufacturing processes.

A numerical method for solving the IHCP problem without initial value. **Yanbo Wang** (Fudan University, PR China) IC/MT2656/047

The inverse heat conduction problem (IHCP) arising in most thermal manufacturing processes of solids has recently attracted much attention. The typical case is the determination of the heat flux on an inaccessible boundary through measurements on an accessible boundary. In the real applications, only discrete data with noise at finite points are available for solving this problem . This problem is known to be extremely ill-posed. Here we will give a numerical method on how to reconstruct the heat flux without initial values. We will also discuss another problem of how to reconstruct the interval length by the measurement data at the boundary without initial values. Numerical examples show that our method is quite effective.

New approach for analytical solutions (by closed formulas) of non-linear direct and inverse problems for intensive steel quenching processes. **Sharif Guseynov** (Latvijas Universitate, Latvia) IC/MT4459/047

Intensive steel quenching (IQ) is one of effective contemporary methods for ecologically clean production of hard and superhard materials. The quality of article in the production process depends on various factors: critical heat fluxes, possible boiling process on the surface of hardware a.o. Some of these factors are difficult to measure experimentally and they must be estimated (calculated) theoretically.

In this paper, we mathematically describe IQ process by non-stationary heat equation (both - classical and hyperbolic) together with non-linear Newton type boundary condition (BC). We offer the new analytical method (by closed formulas) for the solutions of direct problems for both models of heat conduction process with above mentioned non-linear BC.

We solve the coefficient inverse problem for hyperbolic heat equation with non-linear BC in analytical form: we determine *relaxation time* parameter (coefficient at second time derivative in hyperbolic heat equation) assumed by the given temperature distribution at the end of production process.

We solve the initial inverse problem for the classical heat equation with the same non-linear BC: we reestablish the initial temperature distribution for infinite time interval without substantial additional information (we assume only the solution's boundedness).

IC/MP269/047: Inverse problems in financial modelling.

Organiser: Jorge Zubelli (Instituto Nacional de Matemática Pura e Aplicada, Brazil)
Co-organiser: Marco Avellaneda (Courant Institute, NYU, USA)
Co-organiser: Bernd Hofmann (TU Chemnitz, Germany)

The impact of advanced mathematical tools in financial engineering has been growing steadily during the past few decades. During the same period, the theory of inverse problems has been the subject of a lot of attention and has had tremendous impact in several applied fields ranging from medical imaging to geophysics. A number of crucial problems in finances can be cast as inverse problems. Model and volatility calibration is an example of one such problem. It is manifestly ill posed and calls for techniques from the inverse problem theory such as regularization as well as tools from statistics and optimization to handle the massive amount of noisy data.

In this mini-symposium we will present a panorama of practical as well as theoretical issues involved in financial modelling from the perspective of inverse problems. The main goal will be to give emphasis to applications of interest to the financial industry such as option and derivative pricing in different contexts and regimes. To accomplish that goal we will gather a diverse group of researchers some of them directly connected to the financial industry while others will bring in theoretical tools from regularization, asymptotic analysis, jump-diffusion processes and partial differential equations.

A probabilistic approach to inverse problems in option pricing. **Rama Cont** (Columbia University, USA) IC/MT2241/047

The inverse problem of recovering an option pricing model (or risk-neutral process) from a set of given market prices of options, known in finance as the *model calibration* problem, has been treated in the literature either as an exact inversion in presence of continuum data or by applying deterministic optimization methods to a (regularized) least squares formulation of it. These methods yield a single set of model parameters calibrated to market data and ignore the non-uniqueness of the solution, which reflects *model uncertainty*.

We propose a probabilistic approach to the model calibration problem, which takes into account the multiplicity of solutions: starting from a prior distribution on models and a set of observed option prices, we construct a random martingale measure, whose expectation yield an arbitrage-free pricing rule consistent with the observed option prices and whose dispersion properties can be used to quantify model uncertainty. We describe a Monte Carlo algorithm for computing prices under this rule and characterize the limit behavior of the algorithm, which is shown to possess a dual interpretation in terms of minimization of "model risk". This construction only involves a well-posed unconstrained minimization of a convex function, easily performed with gradient-based methods. This algorithm can be seen as a dynamic arbitrage-free version of Avellaneda et al.'s Weighted Monte Carlo algorithm applicable to a wide range of pricing models and products.

Our approach yields a non-trivial posterior distribution, instead of a single price, for exotic options and allows to simulate from this posterior distribution. As an example, we compute the posterior distribution for a barrier option given a set of European calls and puts, in a stochastic volatility model with jumps.

Identification of the speed function in a local Levy model for option pricing. **Heinz Engl** (RICAM Linz, Austria) IC/MT2138/047

Levy-models are a generalization of the well-known Black-Scholes model for option pricing where the asset prices are described by Levy-Processes. Within this class a special type - the so-called local Levy models - have been proposed (Carr et al.). Analogous to local volatility models they depend on an unknown function - the local speed function. We consider the calibration problem of local Levy models for European options, which can be formulated as a nonlinear inverse problem with the local speed function as unknown. This leads to a parameter identification problem in a parabolic partial integro-differential equation. We show that it can be solved in a stable way by nonlinear Tikhonov regularization and prove convergence and convergence rates for the regularized solutions under abstract smoothness conditions (so-called "source conditions"). Furthermore, these smoothness conditions indicate that this problem is more ill-posed than a similar local volatility calibration problem for the Black-Scholes model. Finally, we present the results of a numerical implementation of the regularization.

This work was done in collaboration with Hansjörg Albrecher (Graz Univ. of Tech./ RICAM Linz), Philipp Mayer (Graz Univ. of Tech.) and Stefan Kindermann (Ind. Math. Inst, University of Linz).

Estimating exponential Lévy models from option prices via Tikhonov regularization. **Moeiz Rouis** (École Polytechnique Palaiseau, France) IC/MT5026/047

In the class of exponential Lévy models [1], the dynamics of an asset is described by its diffusion coefficient $\sigma \geq 0$ and its Lévy measure ν, a positive (possibly infinite) measure on $R \setminus \{0\}$ verifying

$$\int \min(1, x^2)\nu(dx) < \infty, \qquad \int \nu(dx)e^x < \infty.$$

Option prices can then be shown to solve a partial integro-differential equation (PIDE) [2]. The model calibration problem in this context concerns the identification of the parameters (σ, ν) of the PIDE from a finite number of option prices. We propose a method which yields a stable solution for this *ill posed inverse* problem, using a Tikhonov regularization method plus a suitable parametrization of Lévy measure. We solve the resulting optimization problem by a gradient-based method where the gradient is computed by solving an adjoint PIDE with an explicit-implicit finite difference method [3]. We discuss theoretical aspects of the regularization procedure and test the performance of the algorithm on simulated data and market prices of options.

Coefficient reconstruction in jump-diffusion models and interest rate modeling. **Cecilia Mancini** (Università di Firenze, Italy) IC/MT2964/047

We introduce a nonparametric technique to reconstruct the coefficients of a univariate jump-diffusion process when we have discrete time observations. The drift, diffusion and jump intensity functions are level dependent. The estimator of the diffusion coefficient is consistent even if the jump process has infinite activity. Our results rely on the fact that it is possible to disentangle the discontinuous part of the state variable through those squared increments between observations exceeding a suitable threshold. We apply our technique to re-examine the estimation of models for the short interest rate. With respect to alternative estimates, the proposed threshold technique provides narrower confidence intervals and, in some cases, very different results from those in the literature.

Nature of ill-posedness and regularization of some benchmark problems in inverse option pricing. **Bernd Hofmann** (TU Chemnitz, Germany) IC/MT2315/047

Inverse problems in option pricing are frequently regarded as simple and resolved if a formula of Black-Scholes-type defines the forward operator. However, precisely because the structure of such problems is straightforward, they may serve as benchmark problems for studying the nature of ill-posedness occurring in the context of volatility calibration. In the first part of this talk, using a Hilbert space setting we analyze the inverse problem of calibrating a purely time-dependent volatility function from a term-structure of option prices by solving an ill-posed nonlinear operator equation in spaces of integrable functions over a finite interval. The smoothing forward operator of the inverse problem under consideration is decomposed into an inner compact linear convolution operator and an outer nonlinear Nemytskii operator determined by the Black-Scholes function. The nature of ill-posedness of the nonlinear composition problem is considered by means of the character of regularized solutions using Tikhonov's method. For the particular case of L^2, a detailed analysis of convergence rates is given, including the interpretation of the corresponding source conditions, which are related to multiplication operators. The second part of the talk is concerned with the singular case of at-the-money options, which plays an interesting role for the benchmark problem. For that case the Fréchet derivative of the forward operator degenerates. Consequently, the classical analysis of convergence rates established by Engl et al. 1989 cannot be applied directly. The talk presents an alternative approach based on Bregman distances bridging the gap between this singular case and the case of in-the-money and out-of-the-money options with respect to the benchmark problem. This is partially joint work with Torsten Hein (Chemnitz), Otmar Scherzer, Christiane Pöschl (Innsbruck) and Barbara Kaltenbacher (Stuttgart). Research is supported by DFG HO1454/7-1.

On maximum entropy regularization and descriptive regularization for parameter identification in a model with time-depending volatility. **Romy Krämer** (TU Chemnitz, Germany), Matthias Richter (TU Chemnitz, Germany) IC/MT2237/047

We consider two inverse problems of parameter identification in the generalized Black–Scholes model, where the asset price P_t at time t is described by

$$dP_t = \mu P_t\, dt + \sigma(t) P_t\, dW_t$$

with a time-dependent volatility fuction $\sigma(t)$ $(0 \leq t \leq T)$. As data we use maturity-dependent option prices $u(t)$ $(0 \leq t \leq T)$.

The first part of the talk is concerned with the inverse problem of identifying the squared volatility function $a(t) := \sigma^2(t)$ over the time interval $[0, T]$. By formulating this inverse problem as a nonlinear operator equation

$$F(a) = u \tag{1}$$

we discuss ill-posedness effects and the applicability of maximum entropy regularization, where the regularized solution a_α^δ is a minimizer of

$$\|F(a) - u^\delta\|^2 + \alpha \int_0^T a(\tau) \ln\left(\frac{a(\tau)}{\overline{a}(\tau)}\right) d\tau.$$

In this context u^δ denotes the noisy data and $\overline{a} \in L^\infty(0, T)$ a fixed reference function. We present results concerning convergence and convergence rates of the regularized solution

and compare the performance of maximum entropy regularization with Tikhonov regularization by means of a numerical case study.

The second part of the talk is devoted to the identification of the antiderivative

$$S(t) := \int_0^t \sigma^2(\tau)\, d\tau \quad (0 \le t \le T)\,.$$

As a motivation we point out that for pricing European call and put options (or more generally claims for which the final payoff depends only on the asset price at the maturity) the knowledge of S is sufficent. This inverse problem can be formulated as

$$N(S) = u\,, \tag{2}$$

where the forward operator N mapping in $C[0,T]$ is of Nemytzkii type. We classify the instabilities which occur in this situation as ill-conditioning effects and discuss the stabilizing effects of *a priori* information concerning the monotonicity of S.

On decoupling of volatility smile and term structure in inverse option pricing. **Torsten Hein** (TU Chemnitz, Germany) IC/MT2168/047

The identification of local volatility surfaces from market data of European Vanilla options is one very important example of inverse problem that arises in mathematical finance. As many other parameter identification problems, the reconstruction of local volatility surfaces is ill-posed, and reasonable results can only be achieved via regularization methods. Moreover, due to sparsity of data, the local volatility is not uniquely determined, but depends strongly on the kind of regularization norm used and a good a-priori guess for the parameter.

By assuming a multiplicative structure for the local volatility, which is motivated by the specific data situation, the inverse problem can be decomposed into two separate subproblems. This removes part of the non-uniqueness and allows to establish convergence and convergence rates under weak assumptions. Additionally, a numerical solution of the two subproblems is much cheaper than that of the overall identification problem.

The talk present joint work with Herbert Egger (Linz) and Bernd Hofmann (Chemnitz).

Inverse problems and regularization techniques in option pricing. **Jorge Zubelli** (Instituto Nacional de Matemática Pura e Aplicada, Brazil) IC/MT2552/047

In this talk we shall give an overview of a number of challenging mathematical problems that appear in the process of model calibration in financial applications related to option pricing. This will serve as a way of connecting many of the topics covered by the different speakers in the rest of the minisymposium.

A typical representative of the class of problems under consideration is that of determining the (local) volatility from quoted option prices. One usual approach to this problem is through Dupire's formula. At that point, we will also look at some directions for generalization of Dupire's formula for the local volatility in the case of baskets of options and several assets. This is joint work with P. de Napoli and P. Amster (UBA-AR).

Finally, we will discuss calibration of stochastic volatility models under different asymptotic regimes. This is joint work with M.O. de Souza (UFF-BR).

IC/MP509/015: Strongly-nonlinear phenomena: theory, integrability and applications to hydrodynamics, Bose–Einstein condensation and biology.

Organiser: Alejandro Aceves (University of New Mexico, USA)
Co-organiser: Tomáš Dohnal (ETH Zürich, Switzerland)
Co-organiser: Pavel Lushnikov (University of New Mexico, USA)

Numerous physical processes exhibit strong enough nonlinear effects to qualitatively alter the dynamics and produce phenomena that are completely foreign to linear dynamics. Examples of such systems relevant to this minisymposium include solitons or solitary waves in free surface hydrodynamics, internal waves, wave breaking in hydrodynamics, modulational instability, extreme waves in deep water, etc. A striking quality of some of the governing nonlinear partial differential equations is their complete integrability.

This minisymposium will address the latest results on mathematical modeling of the physical processes and analysis of the corresponding equations, their structure and solutions.

Transcitical flow over a step. **Roger Grimshaw** (Loughborough UNiversity, UK) IC/MT3708/015

In both the ocean and the atmosphere, the interaction of a density stratified flow with topography can generate large-amplitude, horizontally propagating internal solitary waves. Often these waves appear as a wave-train, or undular bore. In this talk we focus on the situation when the flow is critical, that is, the flow speed is close to that of a linear long wave mode. In the weakly nonlinear regime, this is modeled by the forced Korteweg de Vries equation. We will review how WhithamŠs modulation theory has been applied to obtain an analytical description of undular bores for flow over isolated obstacles, and then show how the same approach can be used for flow over a step.

Freak waves and dissipation due to wave-breaking. **Vladimir Zakharov** (University of Arizona, USA) IC/MT4850/015

Freak Waves add Dissipation due to Wave Breaking

Dispersive and non-classical shocks in the hyperbolic continuum-limit of FPU lattices. **Jens Rademacher** (CWI, Amsterdam, The Netherlands), Michael Herrmann (Humboldt-Universität zu Berlin, Germany) IC/MT3886/015

We consider the continuum limit of FPU chains (i.e., nearest neighbour coupled particles in a Newton potential) under hyperbolic scaling of particle index and time for shock-type Riemann problems. For the linear chain, Alexander Mielke has recently given a rather complete characterization in terms of Wigner measures for more general data. In particular, for oscillation free initial data, the limit is well described by the linear wave equation. In the nonlinear case, the description is much more delicate and is not contained in the naive limiting p-system of mass and momentum conservation. The measure valued limit still conserves mass, momentum and energy, which rules out Lax shocks. For the Toda potential and zero dispersion limits of some PDEs it is known that shocks are dispersive in nature. Recently, Whitham modulation equations of wave trains were formally deduced to describe the arising oscillations in more generality. We numerically confirm this ansatz and present evidence that for non-convex flux shocks can be undercompressive; i.e., non-classical. Such shocks are oscillation free and can be described by the underlying p-system.

Multi-dimensional compactons in nonlinear wave equations. **James Hyman** (Los Alamos National Laboratory, USA), Philip Rosenau (Tel Aviv University, Israel) IC/MT5055/015

Most solitions are one-dimensional waves, even in multidimensional equations. Solitons are nonlinear traveling waves where the nonlinearity and dispersion are balanced to create a stable coherent local environment so that that the solitions maintain their coherence when colliding with other solitions. Because the same dispersive operators are much stronger to two and three dimensions than in one dimension, this balance is usually lost when a one-dimensional equation is generalized to higher dimensions. We restore the balance by making the dispersion weaker in a class of KdV and regularized long wave equations to create fully two- and three-dimensional solutions.

Aggregation and critical collapse of bacterial colonies. **Pavel Lushnikov** (University of New Mexico, USA) IC/MT3593/015

Motion of bacteria can be described in microscopic limit through bacterial density. Bacteria secret chemical which attract other bacteria. Diffusion of emitted chemical provides highly nonlocal mechanism of attraction between bacteria. Nonlinear dynamics of bacterial colonies is described by Keller-Segel model which is dissipative but has many features which are strikingly reminiscent of nonlinear Schrödinger equation, including critical collapse in 2D and supercritical collapse in 3D. Typical evolution of 2D bacterial colonies in experiment is very slow (on scale of hours) until at some region of space the bacterial density exceeds critical value. After that bacterial colonies collapse on a scale of several minutes. Critical collapse of bacterial colonies has self-similar form with spatial scale $(t_0 - t)^{1/2}$, however, corrections to that law is not of loglog form, well known for nonlinear Schrödinger equation, but rather the exponent of the square root of logarithm of $(t_0 - t)$, which makes these corrections noticeable even for moderate bacterial densities. To prevent singularity of bacterial density, the finite size of bacteria should be taken into account. Large bacteria moves through random fluctuations of their membranes. The modified Keller-Segel equation is derived for the probability distribution function of membrane fluctuations which includes contact interaction between bacteria and prevents formation of singularities of bacterial density.

Stationary dispersive shock waves and oblique solitons in Bose-Einstein condensates. **Gennady El** (Loughborough University, UK), Arnaldo Gammal (Universidade de São Paulo, Brazil), Anatoly Kamchatnov (Russian Academy of Sciences) IC/MT3792/015

Recent experiments on expanding Bose-Einstein condensates (BEC) have revealed two types of patterns related to the formation of dispersive shock waves (DSW). One of them is connected with the breaking of the density profile in a freely expanding condensate and was studied by several authors both numerically and, in relevant approximations, analytically.
Another type of DSWs represents a counterpart of the stationary oblique compression jumps of traditional gas dynamics and is formed in the supersonic flow of a BEC past an obstacle. We develop a theory of such spatial DSWs in the frame of the time-independent, two-dimensional Gross-Pitaevskii equation. Corresponding analytical solutions for the asymptotic wave form of the DSW and for the accompanying linear "ship-wave" pattern before the obstacle are obtained and shown to be in excellent agreement with the density profiles in our full time-dependent numerical simulations. The possibility of observation of optical counterparts of the described multi-dimensional wave patterns in a BEC is discussed.

Localized modes in the nonlinear Schrödinger equation with periodic nonlinearity and periodic potential. **Vladimir Konotop** (Universidade de Lisboa, Portugal), Yuli Bludov (Universidade de Lisboa, Portugal) IC/MT3950/015

We consider spatially localized solutions of the nonlinear Schrödinger equation with periodic nonlinearity and periodic potential, concentrating on phenomena originated by competition between the two periodic terms. More specifically, we list physical problems governed by the model, describe numerical results on different branches of the solutions, discuss their stability and bifurcations, analyze asymptotic of the solutions near the different gap edges, and present lattice models generated by the Wannier function expansion of the original equation.

Interaction of two-colour spatial solitons in nematic liquid crystals. **Benjamin Skuse** (University of Edinburgh, UK) IC/MT4428/030

The interaction of two spatial solitary waves based on coherent light of two different wavelengths in a nematic liquid crystal (NLC) is investigated, such solitary waves being termed nematicons. In the local limit it will be shown that two colour nematicons are governed by a system of two saturable, coupled nonlinear Schrödinger (CNLS) equations. Approximate evolution equations for the beam parameters are derived using a hybrid variational technique which includes the effect of diffractive radiation shed as the beams propagate and interact. The approximate method will be presented briefly and solutions of the resulting approximate equations will be compared with numerical solutions of the full governing nematicon equations.

IC/MP508/015: Strongly-nonlinear phenomena in optical and/or periodic media.

Organiser: Tomáš Dohnal (ETH Zürich, Switzerland)
Co-organiser: Pavel Lushnikov (University of New Mexico, USA)

Numerous physical processes exhibit strong enough nonlinear effects to qualitatively alter the dynamics and produce phenomena that are completely foreign to linear dynamics. Examples of such structures relevant to this minisymposium include solitons or solitary waves in optical fibers and photonic crystals and catastrophic collapse and filamentation of laser pulses in many nonlinear media including atmosphere and plasma. These phenomena often cause strong dissipation or dispersion which prevents singular behavior such as classical shocks or blow-up.
This minisymposium will address the latest results on formulation of the corresponding mathematical models, their analysis and numerical approximations as well as on the relevant experimental achievements.

Time-domain simulations of nonlinear Maxwell's equations using Krylov-subspace methods. **Kurt Busch** (Universität Karlsruhe, Germany), Martin Pototschnig (Universität Karlsruhe, Germany), Jens Niegemann (Universität Karlsruhe, Germany), Lasha Tkeshelashvili (Universität Karlsruhe, Germany) IC/MT3717/015

Recent progress in micro- and nano-structuring of photonic materials with strongly nonlinear properties and/or embedded optically active elements such as quantum dots requires the quantitative modeling of ever more complex optical systems. In order to address this challenge, We propose a Krylov subspace based operator-exponential approach for solving nonlinear Maxwell's equations in the time domain. This approach exhibits significantly better performance than the standard Finite-Difference Time-Domain (FDTD) method as well as the classical Runge-Kutta scheme. In addition, our approach is flexible enough to incorporate various coupling effects of the electromagnetic fields with other physical systems and, therefore, is able to handle complex nonlinear problems.

Existence of (generalized) breathers in periodic media. **Guido Schneider** (Universität Stuttgart, Germany) IC/MT3865/015

Modulating pulse solutions consist of a pulse-like envelope advancing in the laboratory frame and modulating an underlying wave-train; they are also referred to as 'moving breathers' since they are time-periodic in a moving frame of reference. In this talk we discuss the existence of such solutions in periodic media using spatial dynamics and invariant manifold theory. Depending on the spectral gaps they can exist as breathers or generalized breathers, i.e. with small tails at infinity.

Gap solitons in a 2D periodic medium. **Dmitry Pelinovsky** (McMaster University, Canada) IC/MT3455/015

We address a two-dimensional nonlinear elliptic problem with a finite-amplitude periodic potential. For a class of separable potentials, we study bifurcation of the first band gap in the spectrum of the linear Schrödinger operator and the relevant coupled-mode equations to describe this bifurcation. We show analytically and numerically that the truncated coupled-mode equations admit a two-dimensional localized solution called a gap soliton. Persistence of the two-dimensional gap solitons of the coupled-mode equations in the full nonlinear elliptic problem is proved with rigorous analysis of Lyapunov–Schmidt reductions in the Fourier space.

Surface gap solitons at a nonlinearity interface. **Tomáš Dohnal** (ETH Zürich, Switzerland) IC/MT3830/015

We demonstrate existence of waves localized at the interface of two nonlinear periodic media with different coefficients of the cubic nonlinearity via the one-dimensional Gross–Pitaevsky equation. We call these waves the surface gap solitons (SGS).

In the case of smooth symmetric periodic potentials, we study analytically bifurcations of SGS's from standard gap solitons and determine numerically the maximal jump of the nonlinearity coefficient allowing for the SGS existence. We show that the maximal jump vanishes near the thresholds of bifurcations of gap solitons.

In the case of continuous potentials with a jump in the first derivative at the interface, we develop a homotopy method of continuation of SGS families from the solution obtained via gluing of parts of the standard gap solitons and study existence of SGS's in the photonic band gaps. We explain the termination of the SGS families in the interior points of the band gaps via the bifurcation of linear bound states in the continuous non-smooth potentials.

Intense optical pulses at UV wavelength. **Alejandro Aceves** (University of New Mexico, USA) IC/MT3633/015

To control and guide electrical discharges in air over distances of several meters a proposal is to ionize filaments of intense optical pulses, preferably at UV wavelength, combined with long infra-red pulses for plasma heating.

In this paper we study conditions of steady formation of pulse filaments coexisting with plasma formation. By numerical means, we derived stationary solutions of the governing nonlinear equations and discuss their stability. A goal of this project is to propose conditions on the plasma and features of the pulse for experimental realizations.

Nonlinear filamentation dynamics. **Daniele Faccio** (Università degli Studi dell'Insubria Como, Italy), Paolo Di Trapani (Università degli Studi dell'Insubria Como, Italy) IC/MT4847/015

We shall give an overview of ultra-short laser pulse filamentation dynamics as viewed within what we may call the X Wave model. Indeed, optical filamentation finds a particularly convenient description in terms of the spontaneous formation of stationary conical wave-packets in particular, in normal GVD, X Waves. We describe the experimental techniques implemented to analyze the strongly coupled space-time filament dynamics. Full angle-wavelength spectral analysis highlights the formation of conical emission, associated to X Wave formation, and axial supercontinuum, related to shock front formation. The spectra bear evidence of the well-known pulse splitting process associated to filamentation and that is here explained as the result of the spontaneous parametric generation and interaction of two X Waves that travel sub and super-luminally with respect to the input pump pulse. The interesting point is that while trailing shock fronts are expected as part of the filament dynamics and have been used to explain the blue shifted on-axis supercontinuum generation, measurements and numerics in condensed media clearly show evidence also of rising shock fronts within the same wave-packet. This finding, not explained by the standard approach to self-steepening and shock front formation, finds a natural explanation in the superluminal group velocity of the spontaneously formed X Waves. A brief overview will also be given of ongoing work on seeded filamentation: a weak seed pulse in the presence of an intense filament will undergo severe spatio-temporal reshaping mediated by cross-phase-modulation. This reshaping leads to the formation of an X Wave with a group velocity that is identical to that of the pump filament pulse. This opens the path for tunable generation of intense X Waves for applications.

Dynamics driven by dispersive shocks in the strong nonlinear regime of optics. **Stefano Trillo** (Università degli Studi di Ferrara, Italy), Claudio Conti (Università degli Studi di Roma "La Sapienza", Italy) IC/MT3725/015

We discuss the role of shock waves in recent nonlinear optics experiments conducted in the strongly nonlinear or weakly dispersive regime, and described by the integrable or nonintegrable (nonlocal) semiclassical Schrödinger equation with cubic potential. The hydrodynamic approximation of the starting model allows us to predict the formation of a single or multiple shock waves. We find, however, that the post-shock evolution is regularized by the occurence of fast oscillations caused by dispersive (in the temporal case) or diffractive (in the spatial case) effects, which leads to non-dissipative (collisionless) shocks. In four-wave mixing experiments driven by two interfering laser beams in a defocusing medium, the oscillations take the form of dark soliton channels. The output pattern is determined by collisions of solitons from adjacent periods, and the phenomenon is described in the framework of the scattering transform on the periodic line. In the context of spatial experiments, i.e. diffraction of a single bell shaped beam, it is important to investigate the role of nonlocality which, having a potential averaging effect, could hamper the formation of the shock. Conversely we find that the shock is robust against nonlocality, though the latter can alter the scenario and the output pattern. Moreover an analytic approach valid in the strong nonlocal limit suggests that the shock has impact also on the dynamics in the focusing regime.

Discrete cavity solitons. **Falk Lederer** (Universität Jena, Germany), Oleg Egorov (Universität Jena, Germany) IC/MT3893/015

Discrete systems, such as semiconductor superlattices, molecular chains, waveguides arrays, or coupled pendulums, share many interesting and somehow intriguing features. Following the theoretical predictions the existence of discrete solitons have been experimentally verified in waveguide arrays, being a prominent example for a discrete system, with either cubic or quadratic nonlinearity. Light propagation in such arrays exhibits striking anomalies in comparison with beams propagating in usual continuous systems, such as *discrete diffraction*, which can be controlled in size and sign by the input conditions. Consequently, solitary waves are likewise expected to behave differently in discrete systems. A logical step is to extend these studies towards dissipative systems (nonlinear waveguide array with dielectric mirrors at the end faces: Fabry–Perot cavity) where gain and losses play a significant role. Over the years a bundle of nonlinear effects has been studied in 1D (film) and 2D (bulk) Fabry–Perot cavities (continuous system) where canonical diffraction occurs. The interplay of feedback, loss, gain and nonlinearity leads to a considerably richer dynamical behavior than that observed in conservative systems. The system can adapt to the driving field in different ways, giving rise to multistability, and, as consequences, pattern formation, and other types of spatial self-organization. In particular, so-called cavity solitons (CS) may exist on a stable and preferably flat background. They represent localized defects and can either locally increase (bright CSs) or decrease (dark CSs) the transmission of the Fabry–Perot cavity. Once excited by a local change of the incident field, in principle, they stay forever on a flat holding beam, even if the initial excitation has been switched off. It is only natural to extend these studies towards discrete systems. Recently, the existence and properties of discrete cavity solitons were firstly studied in an array of coupled waveguide cavities endowed with Kerr nonlinearity. These studies have been extended towards quadratic nonlinearities. In the present contribution we discuss the existence, properties, and interactions of various types of discrete cavity solitons exploiting the control of the linear diffraction properties.

IC/MP417/015: Boundary-value problems and integral equations.

Organiser: Pavel Krutitskii (Keldysh Institute of Applied Mathematics RAS, Russian Federation)

The aim of this session is to screen recent developments in boundary value problems and relative theory of integral equation. The emphasis will be given to constructive methods, which either enable us to obtain integral representation for a solution or enable us to study its qualitative properties. Appropriate integral representation can be used in numerical analysis of the problems and in asymptotic analysis. Special attention to be given to theory of singular integral equations which occur in boundary value problems. It is expected that talks will cover the following topics: qualitative methods for boundary value problems, boundary value problems in cracked domains, integral equation methods in scattering theory and in potential theory, boundary value problems for Stokes equations, methods of functional analysis in boundary value problems, elliptic problems in nonsmooth domains, applications of integral equation methods in fluid dynamics; local and asymptotic methods in boundary value problems.

Helmholtz equation in domains bounded by closed curves and open arcs. **Pavel Krutitskii** (Keldysh Institute of Applied Mathematics RAS, Russian Federation) IC/MT474/015

Boundary value problems in planar domains bounded by closed curves and open arcs were not actively treated before though they have many applications. Similar domains model cracked solid bodies or they model several obstacles and screens in a fluid. However problems in domains bounded by closed curves and problems in the exterior of open arcs were treated separately, because different methods were used in their analysis. Problems for the Helmholtz equation in domains bounded by closed curves are reduced to the Fredholm equation of the 2-nd kind in text books on PDEs. Problems in the exterior of open arcs in a plane were reduced by single and double layer potentials to an equation of the 1-st kind with either logarithmic or strong singularity in the kernel (logarithmic for Dirichlet problem, while strong fot Neumann problem). If we combine these two methods for domains bounded by closed curves and open arcs, we obtain integral equation of different type and with different singularities at different parts on the boundary. The analysis of this equation is too complicated. In the present talk we reduce the Dirichlet and Neumann problems for Helmholtz equation in arbitrary domains bounded by closed curves and open arcs to the uniquely solvable Fredholm integro-algebraic equations of the 2-nd kind and index zero by a boundary integral equation approach. So, the classical result known for domains bounded by closed curves is extended to domains with closed and open boundary. Dirichlet and Neumann problems for the propagative Helmholtz equation are studied for exterior domain, while problems for dissipative Helmholtz equation are studied in both interior and exterior domains. Our method enables us to prove well-posedness of each problem (i.e. existence of the unique classical solution) and to obtain integral representation for a solution in the form of potentials.

A boundary-value problem for an infinite elastic strip with a semi-infinite crack. **Hiromichi Itou** (Gunma University, Japan) IC/MT3422/049

In this talk we consider a boundary value problem for an infinite elastic strip with a semi-infinite crack. The mass forces are supposed to be zero; on the crack the free traction boundary conditions are posed. The usage of the plane elastic single and double layer potentials reduces the problem to a system of singular integral equations. It is shown that this system is uniquely solvable in the appropriate Hölder spaces by the Fredholm alternative. This research is a joint project with Prof. Tani of Keio University.

Asymptotic behaviour of solutions of some nonlinear parabolic and elliptic equations with nonlinear boundary conditions. **Vladimir Kondratyev** (Moscow State University, Russian Federation) IC/MT3316/049

Let Ω be a bounded domain in $\mathbf{R^n}$ with a Lipshitz boundary $\partial\Omega$ and L be a symmetric elliptic operator in divergence form:

$$Lu \equiv \sum_{i,j} \frac{\partial}{\partial x_i} a_{i,j}(x) \frac{\partial u}{\partial x_j}$$

where the coefficients a_{ij} are bounded and measurable in Ω. We study the properties of solutions to equation

$$\frac{\partial u}{\partial t} - Lu + f(x,u) = 0 \text{ in } \Omega \times (0,\infty),$$

satisfying to nonlinear boundary value condition

$$\frac{\partial u}{\partial \nu} + g(x,u) = 0,$$

where ν is conormal vector.

Assume $f(x,u)$, $g(x,u)$ satysfy the following conditions:

$$f(x,0) = g(x,0) = f_u(x,0) = g_u(x,0) = 0, \quad f_u(x,u) > 0,\ g_u(x,u) > 0 \text{ for } u \neq$$

We show that any positive solution vanishing at ∞ is asymptotically equivalent as $t \to \infty$ to a solution of non-linear ordinary differential equation of first order

$$\dot{\alpha} = -\frac{\int_\Omega f(x,u)dx + \int_{\partial\Omega} g(x,u)ds_x}{mes\,\Omega}, \quad \alpha(0) = 1.$$

We also study the elliptic problem:

$$\frac{\partial^2 u}{\partial t^2} + Lu - f(x,u) = 0.$$

Theory of generalized J-integral. **Kohji Ohtsuka** (Hiroshima Kokusai Gakuin University, Japan) IC/MT3292/049

Generalized J-integral (abbr. GJ-integral) is proposed in 1981 to describe three-dimensional fracture phenomena. In 1985, GJ-integral is extended to be applicable to various elliptic boundary value problems. Main property of GJ-integral is to catch the singularity of weak solutions in boundary value problems, which is described as follows: Let Ω be a bounded domain in R^N, $f \in L^2(\Omega)^m$ a given function with a integer $m \geq 1$ and $V(\Omega)$ a subspace of $H^1(\Omega)^m$. Find $u \in V(\Omega) \subset H^1(\Omega)^m$ minimizing the potential energy functional $\mathcal{E}(v,\Omega)$. For u, GJ-integral $J_\omega(u,X) = P_\omega(u,X) + R_\omega(u,X)$ is defined as the functional with two parameters an open set ω and a vector field X. Let us say that u is regular in ω, if $u|_{\omega\cap\Omega} \in H^2(\Omega \cap \omega)^m$. If u is regular in ω, then $J_\omega(u,X) = 0$ for all $X \in W^{1,\infty}(\overline{\omega})^N$. Now consider the perturbation $\{\Omega(t)\}_{0\leq t\leq T}$ of the domain Ω and the variational problems finding the minimizer $u(t)$. The main theorem in GJ-integral theory is:

$$\left.\frac{d\mathcal{E}(u(t),\Omega(t))}{dt}\right|_{t=0} = -R_\Omega(u,X) + \int_\Omega \{X \cdot \nabla(f \cdot u) + (f \cdot u)\mathrm{div}\, X\}\, dx$$

Starting from the main theorem, we can derive results on shape sensitivity analysis using the zero property for regularity.

(For abstract, see session #1 above.)

Boundary integral equations and maximum-modulus estimates for the Stokes system. **Werner Varnhorn** (Universität Kassel, Germany) IC/MT1588/015

In the theory of partial differential equations the classical maximum principle is well-known. It states that any non-constant harmonic function u takes its maximum (and minimum) values always at the boundary ∂G of the corresponding domain G. For higher order differential equations as well as for systems of differential equations such a principle does not hold in general. In these cases, however, there is some hope for a so-called maximum modulus estimate of the form

$$\max_G |u(x)| \ \leq\ c \max_{\partial G} |u(x)|, \qquad (1)$$

where c denotes some constant. We prove the validity of an estimate (1) for the linear Stokes system

$$-\Delta u + \nabla p = 0 \quad \text{in } G, \quad \nabla \cdot u = 0 \quad \text{in } G, \quad u = b \quad \text{on } \partial G$$

concerning the unknown velocity vector u and an unknown pressure function p of a viscous incompressible fluid flow via the method of boundary integral equations. Here $G \subset \mathbb{R}^n$ $(n \geq 2)$ is some bounded or unbounded open set having a compact boundary ∂G of class $C^{1,\alpha}$ $(0 < \alpha \leq 1)$.

Boundary-integral method for Stokes flow past porous bodies. **Mirela Kohr** (Universitatea Babeş-Bolyai, Romania) IC/MT2936/049

In this talk we present a new indirect boundary integral method in order to study the Stokes flow of an unbounded viscous incompressible fluid past a porous body of arbitrary shape. The flow inside the porous body is described by the Brinkman model. Asymptotic results related to the force on the porous body are also obtained in both case of large and also low permeability. Several applications and other connected results will be presented.

Quadrature formulas for the periodic functions for solutions to boundary value problems for the Laplace equation. **Alexander Petrov** (Moscow State University, Russian Federation) IC/MT3281/049

We consider boundary value problems for the Laplace equation in planar and axially symmetric domains. Problems are reduced to the Fredholm equation with logarithmic singularity. We discuss quadrature formulas for a certain integral. The integrand in this integral is a periodic function with logarithmic singularity. We obtain a quadrature formula for this integral in case of an even number N of markers at the boundary line. Formula is accurate for all trigonometric polynomials of order N. We obtain the approximation of the Fredholm equation by a system of linear algebraic equations with the high accuracy. The accuracy of the method checked for different hydrodynamics problems: potential flow over many bodies, cavity flow, breaking capillary-gravity waves, Rayleigh-Taylor instability, fluid fluctuation in vessels, cumulative jets forming, inner waves between two flows.

IC/MP1094/025: Analysis and numerical issues in kinetic equations.

Organiser: Jennifer Proft (University of Texas at Austin, USA)
Co-organiser: Irene Gamba (University of Texas at Austin, USA)
Co-organiser: Maria Gualdani (University of Texas at Austin, USA)

To discuss the state of the art, specifically, analytical and computational issues of classical and semi-classical kinetic transport theory and those related to evolution of probability measures. Such issues will involve non-conservative phenomena associated with Boltzmann, Wigner, and Fokker–Planck type equations, their long time dynamics, non-equilibrium states, approximating properties, and numerical discretizations. Discussion of comparisons of deterministic versus stochastic computational schemes.

WENO solvers for the Boltzmann–Poisson system for semiconductor devices. **María Cáceres** (Universidad de Granada, Spain) IC/MT2453/049

Statistical models are used to describe electron transport in semiconductors at a mesoscopic level. The basic model is given by the Boltzmann transport equation for semiconductors in the semi-classical approximation coupled with Poisson's equation, since the electric field is self-consistent due to the electrostatics produced by the electrons and the dopants in the semiconductor.
In this talk we show WENO-solvers for this system for different devices, for the 1-dimensional and 2-dimensional cases. The main differences of the devices are in the material (Si or GaAs) and the geometries (MOSFET or MESFET).
The deterministic numerical scheme is based on WENO finite differences for the advection part and a Runge-Kutta scheme for the evolution in time, after considering the change of variables proposed by Fatemi and Odeh in the parabolic band approximation case and later extended by Majorana and Pidatella for the non-parabolic approximation case (Kane model).

Analysis for the 1-dimensional case for Si were given by Carrillo-Gamba-Majorana-Shu who later extended it for the 2-dimensional case for MESFET devices. The 1-dimensional case for GaAs was studied by Carrillo, Majorana and the author.

Results for the double-gate MOSFETs, where there are two bands of oxide will be presented.

The discontinuous Galerkin method for semiconductor Boltzmann–Poisson system. **Armando Majorana** (Università degli Studi di Catania, Italy), Irene Gamba (University of Texas at Austin, USA), Jennifer Proft (University of Texas at Austin, USA) IC/MT2625/049

The simulation of semiconductor devices has become a standard tool in the construction process. A very detailed description of the transport processes in semiconductors is provided by kinetic transport models. The semi-classical Boltzmann equation coupled with the Poisson equation provides a general theoretical framework for modeling electron transport. Moreover, time-dependent solutions of the Boltzmann equation contain all the information on the evolution of the carrier distribution. Very recently, deterministic solvers to the Boltzmann-Poisson system for two-dimensional devices were proposed. These methods provide accurate results which agree well with those obtained from Monte Carlo simulations. However, a large number of grid points (a few million) is required, when treating two-dimensional problems. This implies a great amount of CPU time for each simulation. In this paper, we propose a new way of discretizing the Boltzmann-Poisson system based on the discontinuous Galerkin method. This allows the use of a not uniform grid and reduces the CPU time. We show the results of some simulations and the comparisons with solutions obtained using WENO scheme.

Stochastic dynamics of long supply chains with random breakdowns. **Christian Ringhofer** (Arizona State University, USA) IC/MT3040/049

We analyze the stochastic large time behavior of long supply chains via a traffic-flow type random particle model. So items travel on a virtual road from one production stage to the next. Random breakdowns of the processors at each stage are modeled via a Markov process. The result is a conservation law for the expectation of the part density which holds on time scales which are large compared to the mean up and down times of the processors.

Scaling dynamics of Smoluchowski's coagulation equations with dust and gel. **Robert Pego** (Carnegie Mellon University, USA) IC/MT3397/049

We study limiting behavior of rescaled size distributions that evolve by Smoluchowski's rate equations for coagulation, with rate kernel $K = 2$, $x + y$ or xy. We find that the dynamics naturally extend to probability distributions on the half-line with zero and infinity appended, representing populations of clusters of zero and infinite size. The "scaling attractor" (set of subsequential limits) is compact and has a Levy-Khintchine-type representation that linearizes the dynamics and allows one to establish several signatures of chaos. In particular, for any given solution trajectory, there is a dense family of initial distributions (with the same initial tail) that yield scaling trajectories that shadow the given one for all time.

IC/MP1094/025: Analysis and numerical issues in kinetic equations. #2

(For abstract, see session #1 above.)

On the blowing-up of solutions to quantum hydrodynamic equations in bounded domains. **Maria Gualdani** (University of Texas at Austin, USA) IC/MT3791/049

The blow-up in finite time for the solutions to the multi-dimensional quantum hydrodynamic model in a bounded domain is proved. The model consists on conservation of mass equation and a momentum balanced equation equivalent to a compressible Euler equations corrected by a dispersion term of the third order in the momentum balance. The proof is based on a-priori estimates for the energy functional for a new observable constructed with an auxiliary function, and it is shown that under suitable assumptions on the initial and boundary data the solution blows up after a finite time.

Semiconductor energy-transport equations and beyond. **Jüngel Ansgar** (TU Wien, Austria) IC/MT4245/049

Parasitic effects in modern semiconductor devices with characteristic lengths of less than 70 nanometer are becoming more and more significant in industrial applications, making necessary an accurate modeling of the physical phenomena. In this talk we will concentrate on thermal effects in semiconductors, modeled by energy-transport equations. These equations can be derived in the diffusion limit from the semiconductor Boltzmann equation using an entropy maximization precedure. The resulting model consists of nonlinear cross-diffusion parabolic equations for the electron density, electron energy density, and electric potential. The equations are discretized employing exponentially fitted mixed finite elements and modern MOS transistors are simulated in two and three space dimensions. Moreover, it will be explained how a complete hierarchy of diffusive higher-order moment equations can be derived from kinetic models, extending the energy-transport model.

Self-similarity for granular gases of inelastic hard spheres. **Clément Mouhot** (Université de Paris–Dauphine, France) IC/MT4392/049

Discontinuous Galerkin approximation of the linear Boltzmann transport equation. **Jennifer Proft** (University of Texas at Austin, USA), Irene Gamba (University of Texas at Austin, USA) IC/MT3786/049

We analyze the problem of numerically solving linear variants of the space inhomogeneous multidimensional linear Boltzmann equation under the action of electrostatic potentials. We develop a discontinuous Galerkin positive preserving discretization and show, based on discrete entropy multipliers, that the discrete method produces a monotone, stable, converging scheme. By using the decaying estimate to statistical equilibrium solutions, we are able to control the domain of definition of the scheme, uniformly in time, and consequently obtain stable error estimates in W^{k+1} spaces. In generaly, deterministic methods can be very accurate for problems in which the solution may or may not be far from thermodynamical equilibrium and high accuracy is required. Additionally, they yield specific details of transient solutions and consequently can be more efficient than the traditional probabilistic Monte Carlo techniques for the computation of transients. Theoretical and numerical results of our scheme are presented.

On mathematical and physical correctness of balance equations for atmospheric dynamics. **Andrei Bourchtein** (Universidade Federal de Pelotas, Brazil), Ludmila Bourchtein (Universidade Federal de Pelotas, Brazil) IC/CT651/042

The partial differential equations of atmospheric dynamics represent a complex system with multiple space and time scales. The time spectrum of actual large scale motions contains as the principal component the slow synoptic processes with characteristic period of one-two days, while faster waves have quite small amplitudes. However, the solutions to the atmosphere dynamics equations are very sensitive to the type of initial values and small perturbations to actual atmospheric fields can generate the fast gravity waves of great amplitude, which are not observed in the real atmosphere.

Contemporary atmosphere forecasting and modeling consists of numerical solution of the governing partial differential equations. The initial conditions supplied by data assimilation schemes are slightly different from actual atmospheric fields. Therefore some restrictions onto initial values should be imposed in order to avoid physically unrealizable oscillations. These restrictions usually form a set of nonlinear stationary partial differential equations (so-called balance equations) to be solved by appropriate numerical method. It is well known that iterative methods of solution diverge for some physically natural types of balance equations, but the cause of this behavior was not clear. The speculations about the reasons of the divergence were centered on two possibilities: shortcomings of the iterative algorithms or ill-posedness of the boundary value problems. In this study, using concept of ellipticity in the sense of Douglis-Nirenberg, we show that boundary value problems for some types of balance equations can be ill-posed, which reflects in divergence of the iterative methods of solution. We also consider some examples of the real atmosphere circulations when ellipticity conditions are not satisfied.

Coefficients of the singularities for elliptic boundary-value problems in polygonal and polyhedral domains. **Boniface Nkemzi** (University of Buea, Cameroon) IC/CT698/042

Solutions of elliptic boundary value problems in domains with corners or edges are known to have singular behaviours even when the data of the underlying problem are very smooth. These singularities affect the accuracy of the finite element method throughout the whole domain. Thus, it is necessary to develop adaptations which improve the accuracy of the finite element approximations.

Using asymptotic methods, it has been shown that the solution u of an elliptic boundary value problem with corner or edge singularities can be broken down into the sum

$$u = w + \lambda S$$

of a regular part w, whose behavior is not affected by the presence of the corners or edges, and a singular part λS, where S is an explicitly known singular solution.

In the numerical solution of such a problem the regular part w is well approximated by the usual finite element methods. Up till date calculating accurately the coefficient (stress intensity factor) λ remains a very serious problem, especially in three dimensions. As such the theoretical results have had very little practical implications.

In this presentation, we consider boundary value problems for the Laplace equations in polygonal and polyhedral domains and derive explicit expressions for the computations of the coefficients of the corner and edge singularities.

Doubly-nonlinear evolution equations with non-monotone perturbations. **Goro Akagi** (Shibaura Institute of Technology, Japan) IC/CT1187/033

The existence of strong solutions to Cauchy problems for doubly nonlinear abstract evolution equations with non-monotone perturbations in reflexive Banach spaces is proved under appropriate assumptions, which allow the case where solutions of the corresponding unperturbed problem may not be unique. To prove the existence, a couple of approximate problems are introduced and delicate limiting procedures are discussed by using various tools from convex analysis and the Schawder-Tychonoff fixed point theorem. Furthermore, applications of abstract evolution equations to nonlinear PDEs are also given.

Coupled system of Korteweg–de Vries equation-type in domains with moving boundaries. **Octavio Vera** (Universidad del Bío-Bío, Chile), Mauricio Sepúlveda (Universidad de Concepción, Chile), Vanilde Bisognin (Universidad Franciscana, Brazil) IC/CT4577/042

We consider the initial-boundary value problem in a bounded domain with moving boundaries and nonhomogeneous boundary conditions for the coupled system of equations of Korteweg - de Vries type. We prove a global existence and uniqueness for strong solutions for the coupled system of equations of Korteweg - de Vries type as well as the exponential decay of small solutions in asymptotically cylindrical domains. Finally, we present a numerical scheme based in semi-implicit finite differences and we give some examples to show the numerical effect of the moving boundaries for this kind of systems.

Function-theoretic approach to anisotropic plane elasticity. **Alexander Soldatov** (Belgorod State Univesity, Russian Federation) IC/CT4728/042

The representation of general solutions of Lamé system of plane elasticity is given with the help of so-called Douglis analytic functions. Using integral representation of these functions the basic boundary value problems for Lamé system are reduced to equivalent singular integral equations on the boundary.

IC/CTS4605/04: Iterative methods, functional differential equations.

Organiser: Juergen Geiser (Humboldt-Universität zu Berlin, Germany)

Seismic sources and waves using iterative operator splitting methods. **Juergen Geiser** (Humboldt-Universität zu Berlin, Germany) IC/CT2880/025

We discuss iterative operator splitting method for wave-equations motivated from a realistic problem in seismic sources and waves. The operator-splitting methods are welknow to solve such complicated multidimensional and multi physics problems. We present an idea for the consistency analysis of the underlying iterative methods as theoretical background. The mathematical methods are analytical sin and cos semi-groups, which represent the solution of a second order ODE. We discuss stable spatial discretization methods for the wave-equation with respect to the boundary conditions. We verify our methods for test problems with known analytical solutions. Multi-dimensional examples in seismic problems are done with the proposed methods. Finally we discuss the results with standard methods.

Tensor-product methods for stochastic problems. **Elmar Zander** (TU Braunschweig, Germany), Hermann Matthies (TU Braunschweig, Germany) IC/CT2414/004

In the solution of stochastic partial differential equations (SPDEs) the in general already huge dimension N of the algebraic system resulting from the spatial part of the problem is blown up by the huge number of degrees of freedom P coming from the stochastic part. The number of degrees of freedom of the complete system will be NP, which poses severe demands on memory and processor time. We will present a way of how to approximate the system by a tensor product (using its Karhunen-Loève decomposition with M terms), which uses only memory in the order of $M(P+N)$, and keeping this representation also inside the iterative linear solvers. Comparisons with full solvers will be given concerning memory and processor time as well as errror estimates and convergence results.

On an abstract Euler–Poisson–Darboux type equations. **Assia Guezane Lakoud** (Annaba University, Algeria), Chaoui Abderrezak (Skikda University, Algeria) IC/CT410/043

In this talk we study a Cauchy boundary value problem generated by Euler–Poisson–Darboux type equations with operator coefficients possessing variable domains. This work has been motivated by a series of recent results on a similar family of problems without singularity, we can mention the works in [2,3]. Under certain conditions on the operator coefficients, in a Hilbert space, we show that the problem is well posed in the Hadamard sense. The proofs rely on a generalization of the well known energy method. First, we derive *a priori* estimates for strong solutions with the help of Yosida operator approximation. Then, using previous results, we show that the range of the operators of our problem is dense.

On the matrices with operator entries. **Djurdjica Takači** (Univerzitet u Novum Sadu, Yugoslavia) IC/CT760/043

In this paper we consider the matrices with Mikusiński operator entries. We construct a method for determining an approximate solution of the matrix equations, which enables calculations with numbers instead of operators. The analysis of the existence of a solution and its character, is done by using the nonsingularity results related to real or complex numbers.

Existence and uniqueness of solution to a nonlinear dead-oil model resulting from oil engineering. **Moulay Rchid Sidi Ammi** (University Of Aveiro, Department of Mathematics„ Portugal) IC/CT800/043

In this paper we study a *dead-oil* isotherm system resulting from classical modelings of oil engineering. We prove the existence of solution using time discretization. The uniqueness is established in a particular class of admissible solutions.

On the approach to the gelation phase of an aerosol. **Hans Babovsky** (TU Ilmenau, Germany) IC/CT4464/044

Gelation is a phase transition at which coagulating aerosol particles (mathematically described by the Smoluchowski equation) cluster to macroparticles. The understanding and numerical simulation of this phenomenon is of high interest in a number of applications.

Particularly interesting is the situation of a coagulating system in a diffusive random environment. Analytic investigations show that stochastic effects eventually turn a stable situation into a metastable one which finally ends up with gelation [1].

Recently, numerical schemes have been proposed for the efficient simulation of the transition to the gel phase [1,2]. This is at present applied to back up and visualize theoretical results and to proceed into domains presently not available to theory.

In the talk, recent analytical and numerical results are presented.

Some results on coupled linear wave equations. **Saadet Erbay** (Isik Üniversitesi, Turkey), Alp Eden (Bogazici University, Turkey), Irma Hacinliyan (Istanbul Technical University, Turkey) IC/CT2327/015

We obtain integral representation of solution to the following coupled linear wave equations

$$\begin{aligned} \phi_{1,xx} - \phi_{1,yy} - \beta\phi_{2,xy} &= f, \\ \phi_{2,xx} - \lambda\phi_{2,yy} - \beta\phi_{1,xy} &= g, \end{aligned} \qquad (1)$$

where $f, g \in L^1(\mathbb{R}^2) \bigcap C(\mathbb{R}^2)$. These equations are the real components of a system that is called a generalized Davey-Stewartson system consisting of a nonlinear Schrödinger type equation for the complex amplitude of a short wave coupled with two linear wave equations for long waves propagating in an infinite elastic medium. This asymmetrically coupled system cannot be decoupled. So we write the system as a first order linear system in terms of characteristics and solve it directly. A representation of solution of the non-homogeneous system is given by

$$\phi_1(x,y) = \int_{\mathbb{R}^2} [K_1(x',y',x,y)\, f(x',y') + K_2(x',y',x,y)\, g(x',y')]\, dx'dy$$

$$\phi_2(x,y) = \int_{\mathbb{R}^2} [K_2(x',y',x,y)\, f(x',y') + K_3(x',y',x,y)\, g(x',y')]\, dx'dy$$

where the kernel functions $K_i(x',y',x,y)$, $(i = 1,2,3)$ are products of Heaviside functions that live on different characteristic lines. Using these integral representations we find upper bounds for the L^∞ norms of solutions as well as the energy of the system.

Quaternionic analysis and applications. **Dimitrios Pinotsis** (University of Reading, UK) IC/CT4545/015

We present two novel applications of the theory of Quaternions: (a) The solution of certain boundary value problems for linear elliptic Partial Differential Equations (PDEs) in four dimensions. (b) The explicit computation of certain three dimensional integrals without integrating with respect to the real variables. Both applications are based on an important formalism in complex analysis, the so called Dbar formalism, and its quaternionic generalizations. The relevant results have been published in [1], [2].

Asymptotic behavior for a general phase-field model with more than two phases. **Angela Jimenez-Casas** (Universidad Pontificia Comillas, Spain) IC/CT4396/015

We consider a generalization of the semilinear phase field model from [1], by using a more general density function which describe the phase separation of mixtures of three or more components, instead of binary mixtures. The main objective of this work is to prove the existence of metastable solutions that evolve very slowly in time, for this general model.

Next, we show several numerically experiments to obtain these metastable patterns in bough cases, for the model with two different phases and for more of two different phases.

Finally we consider a general enthalpy function which allows to study more general couplings between a diffusion field and a phase-field. For instance, the phase field can be seen as the density of bacterial collony or the mass of growing tumor. Analogously, the diffusion field can stand for the density of nutrient. In this case we prove also the existence of the metastable solutions of the generalized system.

Convergence to equilibrium for nonlinear evolution equations. **Hao Wu** (Fudan University, PR China) IC/CT4889/000

In this talk we will present the Łojasiewicz–Simon approach for the study on convergence of global solution to equilibrium for some nonlinear evolution equations subject to dissipative boundary condition. Those nonlinear evolution equations include:

(1) the Cahn–Hilliard equation with dynamical boundary condition;
(2) the damped semilinear wave equation with critical exponent and dissipative boundary condition;
(3) the parabolic–hyperbolic phase-field system with dissipative boundary condition.

The work was done in collaboration with Prof. Maurizio Grasselli and Prof. Songmu Zheng respectively.

Diffraction of light. **Matthias Kunik** (Universität Magdeburg, Germany) IC/CT640/015

The diffraction of light is considered for a plane screen with an open infinite slit by solving the Maxwell-Helmholtz system in the upper half space with the Fourier method. The corresponding solution is given explicitely in terms of the Fourier-transformed distributional boundary fields. The method deals with all components of the electromagnetic field and leads to a modification of Sommerfeld's scalar diffraction theory. Using this approach we can represent each vectorial solution satisfying an appropriate energy condition by its boundary fields in the Sobolev spaces $H^{\pm 1/2}$. This representation includes also solutions with smooth boundary fields, which are not covered by Sommerfeld's solutions of boundary integral equations (or integro-differential equations) with Hankel kernels. On the other hand we show that Sommerfeld's theory using a boundary integral equation for the so called B-polarisation leads in general to vectorial solutions which violate a necessary energy condition. For the physically admissible regular solutions in the upper half space we derive the necessary and sufficient energy conditions in terms of the Fourier transformed distributional boundary fields.

On the asymptotic behavior of the Korteweg–de Vries equation with localized damping. **Ademir Pazoto** (Universidade Federal do Rio de Janeiro, Brazil) IC/CT1881/015

The purpose of this work is to study the exponential stabilization of the Korteweg-de Vries equation posed in the right half-line, as well as, in a bounded domain, under the effect of a localized damping term. Combining multiplier techniques and compactness arguments the problem is reduced to prove the unique continuation property of weak solutions. Here, the unique continuation is obtained in two steps: we first prove that solutions vanishing on any subinterval are necessarily smooth and then we apply the unique continuation results available in the literature. In particular, we show that the exponential rate of decay is uniform in bounded sets of initial data. Similar conclusions remain valid for the critical generalized Korteweg-de Vries equation.

IC/CTS4593/04: Miscellaneous computation.

Linear stability analysis of infiltration fronts for a non-equilibrium Richards equation. **Carlota Cuesta** (University of Nottingham, UK) IC/CT4722/015

Gravity-driven fingers in unsaturated porous media flow have been observed experimentally by a number of researchers. It is known that the standard Richards equation does not suffice to describe instability during infiltration processes. In recent years extensions of the Richards equation have been considered in order to pursue fingering. Among these extensions, an equation containing a third order term with mixed derivatives has been also postulated. This includes the so-called non-equilibrium Richards equation, which results from considering a *dynamic* capillary pressure relation, as suggested by Hassanizadeh and Gray (1993). In this talk we recall our results on existence of travelling waves solutions of the latter. We concentrate in a field soil model for which the diffusivity can be regarded constant. We shall first present an analysis of linear stability of travelling waves in one dimension, and later recall the long-wave stability criterion in higher dimensions. Instabilities are confirmed by means of numerical computations in two dimensions. We shall finally derive and analyse the non-linear evolution equation of the fingers at the instability onset. This equation turns out to be a forward-backward pseudo-parabolic equation.

Systems of multi-dimensional singular integral equations in non-smooth domains: a Noetherian property and index. **Vladimir Vasilyev** (Bryansk State University, Russian Federation) IC/CT3346/015

On manifolds with non-smooth boundaries the Mikhlin–Calderon–Zygmund type operators with a matrix symbol are considered. The singularities of a boundary can be consisting of cones and wedges sheaf. The Noetherian property conditions (wave factorization) and reduction to Atiyah–Singer theorem are described.

These results were obtained through joint work with I.V. Scherbenko.

Variant H-measures and applications. **Martin Lazar** (University of Zagreb, Croatia), Nenad Antonić (University of Zagreb, Croatia) IC/CT1862/015

H-measures have been introduced as a tool for studying quadratic terms of weakly converging L^2 sequences. As such, they have proved appropriate for exploring limits of energy terms. Due to special scaling of the dual variable $(\frac{\xi}{|\xi|})$ included in the definition of H-measures, they have mostly been used for hyperbolic equations and systems. The above scaling turned out to be unsuitable for the applications to equations of parabolic type. Therefore, a variant of H-measures has been developed, containing a different scaling for the dual variable, which is better suited to the equations of this type.

I shall present the construction of the new variant, and its properties. Applications to the heat and Schrödinger equation will be compared with the results obtained by the original H-measures, where the results turned out to be insufficient, as the corresponding H-measures are supported in two points (North/South pole) of the dual space. The new variant gives measures supported on the curves, thus enabling a study of propagation phenomena. The explicit relations between macroscopic energy dissipation term and source term are obtained, as well. Furthermore, application to the non-stationary Stokes system allows us to express the term which appears by homogenisation via the variant H-measure.

Existence of solutions for some quasi-linear elliptic systems with measure data. **Zakaria El Allali** (Université Mohammed Premier Oujda, Morocco), Abdelaziz Chetouani (Université Mohammed 1er Oujda, Morocco), Najib Tsouli (Université Mohammed Premier Oujda, Morocco), El Bekkaye Mermri (Université Mohammed Premier Oujda, Morocco) IC/CT636/015

We are concerned here with the existence of solutions for quasi-linear elliptic systems such as:

$$\begin{aligned} -\Delta u &= au + bv + f_1(x,u,v,\nabla u,\nabla v) + \mu_1 \ \text{ in } \Omega,\\ -\Delta v &= bu + dv + f_2(x,u,v,\nabla u,\nabla v) + \mu_2 \ \text{ in } \Omega,\\ u &= v = 0 \ \text{ on } \partial\Omega, \end{aligned}$$

where Ω is a bounded open set in $\mathbb{R}^N$, $N \geq 2$, $1 < p < +\infty$, a, b, d are given real numbers $\mu_i (i = 1, 2)$ is a Radon measure on Ω and $f_1, f_2 : \Omega \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ are assumed to be Carathéodory functions. We will prove the existence of a solution $(u, v) \in (H_0^1(\Omega))^2$, if and only if the signed measure $\mu_i (i = 1, 2)$ is zero on sets of capacity zero in Ω; i.e $\mu_i(E) = 0$ $(i = 1, 2)$ for every set E such that $\mathrm{cap}_p(E, \Omega) = 0$.

Stable combined compact-difference scheme with an arbitrary boundary condition. **Kazuya Matsuoka** (Nagoya University, Japan) IC/CT4378/038

Direct numerical simulations of the flows with various physical phenomena such as turbulent flows and/or flows generating aeroacoustic noise require high-resolution numerical methods. Recently, implicit finite difference schemes such as the Padé scheme are studied as the high resolution finite difference schemes. One example is a spectral-like Compact Difference (sp-CD) scheme proposed by Lele. However, in order to improve the accuracy of CD scheme, many stencils must be used. Therefore, the treatment of CD scheme at the points near the boundary is different from that at the inner points. Carpenter and Kobayashi shows that the treatment of boundary in CD schemes for the spatial derivatives is important for the stability of time marching equations. Higher derivatives on 3 stencils are used in Combined Compact Difference (CCD) schemes proposed by Chu&Fan and Nihei&Ishii. Using CCD scheme, we can obtain higher accuracy and higher resolution of at the points near the boundary except for the boundary point. However, the stability analysis of CCD schemes is not studied in detail. In this study, we investigate 1) the stability of CCD scheme, 2) a more stable CCD scheme on non-periodic boundary condition and 3) a new scheme for the regular grid system in which the boundary is allocated between regular grid points. The fully discrete equation for 1-D advection-diffusion equations are investigated, in which CCD scheme is used for spatial derivatives and the Runge-Kutta (RK) method is used for the time marching with various Courant number and diffu-

sion number. The stability region was given for periodic and non-periodic boundary conditions. We proposed a new CCD scheme for non-periodic boundary conditions with larger stable region than that for periodic boundary conditions. We also proposed an extended stable scheme for the regular grid system in which the boundary is allocated between regular grid points.

Some types of stability estimates for operator-differential equations and operator-difference schemes. **Boško Jovanović** (University of Belgrade, Yugoslavia) IC/CT675/015

An abstract problem $Au = \varphi$ is called stable if its solution u continuously depends on the input data φ. For linear problems this is equivalent to *a priori* estimate

$$\|u\|_1 \le \varrho \, \|\varphi\|_2$$

where $\|\cdot\|_1$ and $\|\cdot\|_2$ are certain norms. For evolution problems the quantity ϱ in many cases depends on the time variable t. In particular, the behavior of $\varrho(t)$ when $t \to +\infty$ is of interest. If ϱ does not depends on t the problem is called globally stable. If $\varrho(t) \to 0$ when $t \to +\infty$ the problem is called asymptotically stable.

Another type of stability is the strong stability, or the stability of the solution u under perturbations of operator A. Let $\tilde{u}$ be the solution of equation with perturbed operator $\tilde{A}\tilde{u} = \varphi$. A priori estimate of the strong stability have the form

$$\|\tilde{u} - u\|_3 \le \varrho \, \|\tilde{A} - A\|_4 .$$

In this case the problem is nonlinear, even for linear A and $\tilde{A}$, and the quantity ϱ depend on u and $\tilde{u}$. In the case of differential equations operator A is generally unbounded and one must have a suitable definition of its norm.

Present paper deals with the construction of different types of stability estimates for operator-differential equations and operator-difference schemes.

Organiser: Peter Pang (National University of Singapore)

New theory of spatio-temporal chaos in nonlinear systems of partial differential equations. **Nikolai Magnitskii** (Institute for Systems Analysis RAS, Russian Federation) IC/CT4164/040

During several last years, it was proved by author and his pupils that there exists one universal scenario of transition to dynamical chaos in nonlinear dissipative systems of ordinary differential equations, including all classical chaotic systems such as Lorenz, Rossler, Chua systems, Duffing-Holmes and generalized Matie equations and others (see [1] and references there). This scenario begins with the Feigenbaum cascade of period doubling bifurcations of stable cycles, continues by the Sharkovskii subharmonic cascade of bifurcations of stable cycles with arbitrary periods and then continues by the Magnitskii homoclinic cascade of bifurcations of stable cycles convergent to homoclinic contours. In the present talk we consider three systems of partial differential equations: the system of Brusselator equations as an example of a reaction - diffusion system, the Kuramoto-Tsuzuki (Time-Dependent Ginzburg-Landau equation) and the Magnitskii system of market economy equations. We show that at least one universal scenario realizes in all these systems. It is the subharmonic cascade of bifurcations of two-dimensional tori along one or both frequencies. This cascade also can be described by the universal Feigenbaum-Sharkovskii-Magnitskii (FSM) theory. In conclusion we show that the following conjecture is likely to be true: the appearance of spatio-temporal chaos in nonlinear systems of partial differential equations is caused by cascades of bifurcations of two-dimensional invariant tori rather than the destruction of a three-dimensional torus with the generation of some hypothetical strange attractor, as it is assumed in modern publications following the Ruelle-Takens paper [2].

Energy estimates for reaction–diffusion processes of electrically charged species. **Annegret Glitzky** (Weierstraß-Institut Berlin, Germany) IC/CT1313/040

We describe the transport of m different charged species in heterostructures via the processes drift, diffusion and reversible reactions of mass action type. The model contains continuity equations for the densities of all involved species which are coupled with a Poisson equation for the self-consistent calculation of the electrostatic potential which causes the drift of the charged particles. Forced by applications from semiconductor technology, we formulate rather general assumptions concerning the state equations, $u_i = u_i^* g_i(v_i)$, $i = 1, \dots, m$, relating the density u_i and the chemical potential v_i, such that Boltzmann and Fermi-Dirac statistics are included as special cases. Here u_i^* is some reference density depending on the position because of doping or heterogeneous materials. The free energy has the form

$$F = \sum_{i=1}^{m} F_i + F_{el}, \quad F_i(u_i) = \int_\Omega u_i^* \int_{g_i(0)}^{u_i/u_i^*} g_i^{-1}(z) \, \mathrm{d}z \, \mathrm{d}x,$$

where F_{el} denotes the electrostatic part of the free energy. The anti-gradient of the electrochemical potential ζ_i is supposed to be the driving force for the mass flux j_i,

$$j_i = -u_i^* g_i'(v_i) S_i(\cdot) \nabla \zeta_i, \quad i = 1, \dots, m,$$

where the matrix function S_i prescribes the possible anisotropy of the material. Additionally, the inverse Hessian of $F_i(u_i)$ has to be a factor in the flux term for the i-th species. The problem is completed by initial conditions and boundary conditions, which are compatible with thermodynamic equilibrium.

On solutions of the model equations the free energy decays monotonously and exponentially to its equilibrium value. The delicate step in the proof of the exponential decay of the free energy is an estimate of the free energy by the dissipation rate which can be proved indirectly. Moreover, we present energy estimates for related discretized problems.

A positive and conservative second-order finite-volume scheme. **Philipp Andrea Zardo** (Universität Kassel, Germany), Andreas Meister (Universität Kassel, Germany), Joachim Benz (Universität Kassel, Germany) IC/CT2214/040

The longterm development of water quality in rivers and canals strongly depends on phosphorus in both water and sediment as well as on the interaction of phosphorus with algae and zooplankton. Modelling leads to a system of stiff hyperbolic/parabolic partial differential equations. Additionally the crucial *positivity* property of all biological and chemical values and the *conservativity* property concerning the chemical constituents are to be fulfilled by the scheme, to obtain reasonable results.

In this talk a second order (in space and time) finite volume scheme which improves the time integration by weighting the

sink and source terms will be presented. The new scheme extends the modified Patankar-Ansatz by applying the approach also to sink terms and corresponding source terms of all non-conservative and positive constituents. Thus it guarantees the *positivity* similarly for these values, obtains *conservativity* for all *conservative* items and allows equal or larger timesteps Δt than the straight forward use of the underlying CFD-scheme.

Numerical results will be analysed to confirm the theoretical propositions.

Fractional diffusion equation and diffusive stresses. **Yuriy Povstenko** (Jan Dlugosz University, Poland) IC/CT774/040

The classical theory of difusion is based on the Fick law relating the matter flux vector to the concentration gradient. In combination with the balance equation for mass, this equation leads to the parabolic diffusion equation. The time-nonlocal dependence between the flux vector and corresponding gradient with long-tale power kernel can be interpreted in terms of fractional integrals and derivatives and yields the time-fractional diffusion equation. A quasi-static uncoupled theory of diffusive stresses based on this equation was introduced in [1,2]. In the present contribution several problems are solved in the framework of the proposed theory.

Existence and uniqueness for a class of stochastic partial differential equations with application in tumor growth. **Fejzi Kolaneci** (University of New York, Tirana, Albania) IC/CT421/040

We consider the martingale problem associated with a quasilinear stochastic partial differential equation driven by a space-time white noise. Under suitable assumptions, the existence of weak solutions is proved via Girsanov's theorem, by an approximation procedure, and by a tightness argument. Using a moment duality method we investigate the uniqueness in law of the weak solution. The obtained theoretical results are applied to model the tumor growth for dispersed cells regime in the presence of adjuvant chemotherapy, immunotherapy, or gene therapy.

Stationary patterns in diffusive predator–prey models. **Peter Pang** (National University of Singapore) IC/CT4586/040

In this talk, we will describe some recently studied predator–prey models involving diffusion and cross-diffusion. In particular, we will describe our results concerning the existence of stationary patterns. In some of these cases, we find that certain stationary patterns arise only with the presence of cross-diffusion. This illustrates clearly the role played by cross-diffusion in complex population dynamics, such as when the species exercise defensive strategies or when stage structures are present.

Constructing exact solutions of reaction–diffusion–convection equations arising in mathematical biology. **Roman Cherniha** (National Academy of Sciences of Ukraine, Kyiv), Olexii Pliukhin (National Academy of Sciences of Ukraine, Kyiv) IC/CT3055/040

The nonlinear reaction–diffusion–convection (RDC) equation is:

$$u_t = (u^m u_x)_x + \lambda u^n u_x + C(u),$$

where $u = u(t,x)$ is the unknown function, $C(u)$ is an arbitrary smooth function and the subscripts t and x denote differentiation with respect to these variables, n, m and λ are some parameters. This kind of equation generalizes a great number of the known nonlinear equations describing various processes in biology; see, e.g.,[1]. While there is no existing general theory for analytical integrating nonlinear RDC equations of the above form, construction of particular exact solutions for these equations is a non-trivial and important problem. Now the most powerful methods for construction of exact solutions to nonlinear RDC equations are the group-theoretical approaches, which are based on using the Lie and conditional symmetries of a given equation.

In this talk, a complete description of conditional symmetries of the RDC equation is presented[2,3]. Furthermore those symmetries are applied for finding exact solutions of some RDC equations arising in mathematical biology. The exact solutions obtained are also applied for solving nonlinear boundary-value problems, with basic equations of the above form and zero Neumann conditions, and compared with the relevant numerical solutions obtained by a numerical technique[4].

A complete classification of bifurcation diagrams of a p-Laplacian Dirichlet problem. **Shin-Hwa Wang** (National Tsing Hua University, Taiwan) IC/CT1236/004

We study the bifurcation diagrams of classical positive solutions u with $\|u\|_\infty \in (0,\infty)$ of the p-Laplacian Dirichlet problem

$$(\varphi_p(u'(x)))' + \lambda f_{q,r}(u(x)) = 0, \quad \text{for } -1 < x < 1, \text{ with } u(-1) = u(1) = 0,$$

where $p > 1$, $\varphi_p(y) = |y|^{p-2}y$, $(\varphi_p(u'))'$ is the one-dimensional p-Laplacian, $\lambda > 0$ is a bifurcation parameter, and

$$f_{q,r}(u) = \begin{cases} |1-u|^q, & \text{for } 0 < u \le 1, \\ |1-u|^r, & \text{for } u > 1, \end{cases}$$

with positive constants q and r. We give explicit formulas of bifurcation curves of classical positive solutions on the $(\lambda, \|u\|_\infty)$-plane. More importantly, for different (p,q,r), we give a complete classification of all bifurcation diagrams. Hence we are able to determine the (exact) multiplicity of classical positive solutions for each (p,q,r,λ).

A complete classification of bifurcation diagrams of classes of p-Laplacian multiparameter boundary value problems. **Kuo-Chih Hung** (National Tsing Hua University, Taiwan), Shin-Hwa Wang (National Tsing Hua University, Taiwan) IC/CT1240/040

We study the bifurcation diagrams of positive solutions of the p-Laplacian multiparameter boundary value problem

$$(\varphi_p(u'(x)))' + f_{\lambda,\mu}(u(x)) = 0,$$

for $-1 < x < 1$, with $u(-1) = u(1) = 0$, where $p > 1$, $\varphi_p(y) = |y|^{p-2}y$, $(\varphi_p(u'))'$ is the one-dimensional p-Laplacian, and $f_{\lambda,\mu}(u) = g(u,\lambda) + h(u,\mu)$, $\lambda > \lambda_0$, $\mu > \mu_0$ are two bifurcation parameters. We assume that functions g and h satisfy hypotheses ((H1)–(H3) and (H4a)) or ((H1)–(H3) and (H4b)). Under these hypotheses, we give a complete classification of bifurcation diagrams, and we prove that, on the $(\lambda, \|u\|_\infty)$-plane or $(\mu, \|u\|_\infty)$-plane, each bifurcation diagram consists of exactly one curve which is either a monotone curve or has exactly one turning point where the curve turns to the right. Hence the problem has at most two positive solutions for each $\lambda > \lambda_0$ and $\mu > \mu_0$. More precisely, we prove the exact multiplicity of positive solutions. In addition, for $p = 2$ or $p \geq 3$, we give interesting examples which show complete evolution of bifurcation diagrams, as μ or λ varies.

Bifurcation of positive solutions to Hénon equation. **Zhong-hua Yang** (Shanghai Normal University, PR China), Zhao-xiang Li (Shanghai Normal University, PR China) IC/CT1255/040

The boundary value problem of the Hénon equation $g(u,r) = \Delta u + |x - x^0|^r |u|^{q-1}u = 0$ with $x \in \Omega$ and $u|_\Gamma = 0$, is considered, where Δ is Laplace operator, $r \geq 0$, $x = (x_1, x_2)$, $x^0 = (\frac{1}{2}, \frac{1}{2})$, Ω is the unit square, and Γ is the boundary of Ω. The bifurcation method is applied to solving the D_4-symmetric positive solutions of the Hénon equation. Taking r as a bifurcation parameter, the $D_4 - \Sigma_d(D_4 - \Sigma_1, D_4 - \Sigma_2)$ symmetry-breaking bifurcation point is found on the branch of the D_4-symmetric positive solutions of the Hénon equation via the extended system. Finally, $\Sigma_d(\Sigma_1, \Sigma_2)$-symmetric solutions are computed by the branch-switching method based on the Liapunov–Schmidt reduction.

Stability in anomalous reaction–diffusion systems. **Yana Nec** (Technion – Israel Institute of Technology), Alexander Nepomnyashchy (Technion – Israel Institute of Technology) IC/CT84/010

Diffusion is a ubiquitous process, encountered in physics, chemistry and biology. Normal diffusion, i.e. unrestricted random walk, is often not a satisfactory model. For instance, diffusion in gels (especially bio-gels), porous media and polymers is slower than normal. On the other hand, the transport in plasma or turbulent flows is enhanced. Pattern formation in such anomalous systems, governed by integro-differential equations, is still hardly investigated. In this contribution we focus on two most non-trivial cases: (i) Turing instability in sub-diffusive systems; (ii) longwave oscillatory instability in super-diffusive systems.

We first treat the case of equal anomaly exponents of the reacting components. We find that the wave number range of monotonously growing disturbances is semi-infinite and is shifted into the short wave region when the diffusion coefficients' ratio approaches its critical value. There are two unstable modes per wave number in that range. For longer waves an oscillatory mode is present, unstable even when the coefficients' ratio exceeds its critical value for the monotonous modes. An exact formula is derived for the critical value of the coefficients' ratio, corresponding to the threshold of oscillatory instability in a sub-diffusive system.

In the case of distinct anomaly exponents, we show that when the exponents' difference is in favour of the inhibitor (activator) and of unity order, the system is unstable (stable). When the exponents' difference is small, an intermediate range of unstable wave numbers, dependent on the diffusion coefficients' ratio, is observed.

Also, we consider the case of a long wave oscillatory instability in a super-diffusive system. It is shown that near the instability threshold the problem is governed by a super-diffusive modification of the complex Ginzburg-Landau equations. We investigate the modulational instability of homogeneous oscillations and traveling waves, and discuss its nonlinear development.

Stationary solutions to a climate model with a nonlinear diffusive boundary condition. **Lourdes Tello** (Universidad Politécnica de Madrid, Spain) IC/CT4326/040

We study a model based in one proposed by R.G. Watts and R. Morantine ("Rapid climatic change and the deep ocean", Climatic Change 16, (1990) pp.83–97) modelling the temperature coupling surface deep ocean. The model consists of an equation of parabolic type for the temperature in a global ocean with a dynamic and diffusive nonlinear boundary condition. The boundary condition is obtained through a averaged global energy balance for the atmosphere surface temperature.

We prove that the number of stationary solutions depends on a parameter Q, which appears in the boundary condition modelling the amplitude of the source term induced by the superficial co-albedo.

This is a work in collaboration with J.I. Diaz (Univ. Complutense de Madrid).

Homogenization of scalar conservation laws with vanishing viscosity. **Anne-Laure Dalibard** (Université de Paris–Dauphine, France) IC/CT4324/041

We study the behavior as $\varepsilon \to 0$ of the solutions of the equation

$$\partial_t u^\varepsilon + \mathrm{div}_x \left[A\left(\frac{x}{\varepsilon}, u^\varepsilon\right)\right] - \varepsilon \Delta_x u^\varepsilon = 0, \quad t > 0,\ x \in \mathbb{R}^N,$$
$$u^\varepsilon(t=0,x) = u_0\left(x, \frac{x}{\varepsilon}\right)$$

where A is a given nonlinear flux, periodic with respect to its first variable. The homogenized problem can be computed by means of formal two-scale expansions.

When the initial data is already adapted to the micro-structure, the function u^ε behaves in L^1_{loc} as $v(x/\varepsilon, \bar{u}(t,x))$ as $\varepsilon \to 0$, where v is determined by a cell problem and $\bar{u}$ is the solution of the homogenized problem. The proof relies on the use of a kinetic formulation adapted to the parabolic conservation law.

When the initial data is not well-prepared, there is an initial layer during which the solution adapts itself to match the profile dictated by the environment. The typical size of the initial layer is of order ε. The proof relies strongly on the parabolic form of the equation; in particular, no condition of nonlinearity on A is required.

We also tackle the associated hyperbolic problem, i.e. the homogenization of equation $\partial_t u^\varepsilon + \mathrm{div}_x [A(x/\varepsilon, u^\varepsilon)] = 0$. We prove that a strong convergence result holds, even though the identification of the asymptotic profile is in general an open problem.

Approximation of highly conductive thin sheets with asymptotic expansion. **Kersten Schmidt** (ETH Zürich, Switzerland), Sébastien Tordeux (INSA Toulouse, France) IC/CT3101/041

Sensitive measurement and control equipment is protected from disturbing electromagnetic fields by thin shielding sheets[3]. Alternatively to discretisation of the sheets, the electromagnetic fields are modeled only in the surrounding of the layer taking them into account with the so called Impedance Boundary Conditions (IBCs) [4,2].

We study the shielding effect by means of the model problem of a diffusion equation with additional dissipation in the curved thin sheet. We use asymptotic expansion techniques [1] to derive a limiting problem (namely, as the thickness of the sheet ε tends to zero), as well as modelling contributions to the solution of higher orders in ε. These problems are posed in the limiting regime of vanishing ε, with a condition for a jump in the solution and it's normal derivative. This avoids having to use a mesh for the computational domain, even just locally, at the scale of ε.

We derive the problems for arbitrary order and show their existence and uniqueness. Numerical experiments for the problems up to second order show the asymptotic convergence of the solution to appropriate order in the thickness parameter ε.

Method of multiple scales with three time scales. **Peter Kramer** (Rensselaer Polytechnic Institute, USA), Adnan Khan (Rensselaer Polytechnic Institute, USA), Robert DeVille (Courant Institute, NYU, USA), Philip Stathos (Rensselaer Polytechnic Institute, USA) IC/CT3539/041

Some confusion appears in the literature regarding the extension of the method of multiple scales to three or more time scales. While the work of Murdock and Wang correctly indicate some obstructions to such an extension in some types of problems, other work suggests that the extension should almost never be possible. These pessimistic results generally follow from the imposition of additional restrictions in the calculation, which really are not necessary. We will show on some simple ODE models how a systematic implementation of the method of multiple scales can succeed in correctly capturing three active time scales, though more calculation is required than one might expect from naive considerations. On the other hand, an extension of the method of averaging to three time scales produces an incorrect approximation in these problems. We will also discuss the method of multiple scales to two PDE systems with three time scales: one involving transport by a periodic velocity field with a strong mean flow and one involving the stochastic dynamics of a particle in a metastable potential.

A new shallow water model, by asymptotic analysis, with linear dependence on depth. **Raquel Taboada-Vázquez** (Universidade da Coruña, Spain), Jose Manuel Rodriguez Seijo (Universidade da Coruña, Spain) IC/CT1570/041

In this paper, we study the Euler equations in a domain with small depth. With this aim, we introduce a small adimensional parameter ε related to the depth and we use asymptotic analysis to study what happens when ε becomes small.

Usually, when used asymptotics to analyze fluids, they are used in the original domain (see[2]), that in this case depends on parameter ε and time t^{ε}, or the surface is supposed to be constant. We, however, shall use the asymptotic technique in the same way as in [1] and related works, that is, we do a change of variable to a reference domain independent of the parameter ε and the time.

In this way we obtain a model for ε small that, after coming back to the original domain, gives us a shallow water model that considers the possibility of a non constant bottom and the horizontal velocity components depend on z if the vorticity is not zero. This represents an interesting novelty respect to the shallow water models found in the literature. We stand out that we do not need to make *a priori* assumptions about velocity or pressure behavior to obtain the model.

The new model is able to calculate exactly the solutions of Euler equations that are linear in z, whereas the classic model just obtains the averaged velocities.

The analytical calculations of the parameters of the fluctuations of the ballistic missiles. **Vladimir Gordon** (Orel State Technical University, Russian Federation), Pavel Anokhin (Orel State Technical University, Russian Federation), Svetlana Ovsyannikova (Orel State Technical University, Russian Federation) IC/CT4074/041

The analytical calculations of natural frequencies and forms of the longitudinal and flexural vibrations of the heterogeneous rods, which simulate ballistic missiles, are proposed. These objects are characteristic by significant drops in the distribution of stiffness and density along the length. The indicated dynamical characteristics knowledge is necessary for the design of the system of control and evaluation of the strength of articles.

Traditionally /1/ calculation is produced by the very labor-consuming method of sequential approximations.

It is proposed to use the analytical method, operational and effective for the arbitrary laws of distribution of stiffness and densities, for the purpose of the reduction of time and cost of dynamic calculations at the stage of preliminary design (selection of layout, sizes and materials).

The mathematical model of the dynamics of ballistic missile are differential equations of the second and the fourth orders with the variable coefficients and the corresponding boundary and initial conditions, and also different assumptions and limitation. The essence of the proposed method is based on the ideas of the asymptotic phase integral method of Wentzel-Kramers-Brillouin and method of Liouville-Steklova /2/. According to the proposed method the calculation of the natural frequencies of oscillation is reduced to the calculation of several dozens simple integrals. The comparison of the executed calculations with the results, obtained by approved traditional method shows the high accuracy of the proposed method (divergence $< 2\%$). Advantages of the method: analyticity, small labor expense, clarity, universality. For these reasons it is recommended for putting into practice of design.

Numerics, characteristics, asymptotics: a case study from large-scale ocean circulation. **Frank Hodnett** (University of Limerick, Ireland) IC/CT504/171

This paper uses a partial differential equation which occurs in a reduced model of large scale circulation in an ocean basin as an educational vehicle through which to demonstrate the usefulness of a set of mathematical techniques in analyzing the equation. A parameter occurring in the equation does in reality vary from very small through intermediate to very large values. Therefore separate solutions are required for (a) very small, (b) very large and (c) intermediate values of the parameter. This allows for the demonstration of how, when the parameter is very small, the method of characteristics and the singular perturbation method are useful. When the parameter is very large the regular perturbation method is useful. At intermediate values of the parameter numerical methods must be used and in this case it is a helpful check to have available the asymptotic results for both small and large values of the parameter.

On the Stokes problem in cylinders becoming unbounded. **Sorin Mardare** (Universität Zürich, Switzerland), Michel Chipot (Universität Zürich, Switzerland) IC/CT2482/041

We establish that the solution to the Stokes problem in a cylinder becoming infinite in the direction of its axis converges to the solution to the Stokes problem defined on the basis of the cylinder, if the applied forces are orthogonal to the axis of the cylinder and independent of the coordinate along this axis.

Exact equations of motion for smoothed Wigner transforms and homogenization of wave propagation. **Agissilaos Athanassoulis** (Wolfgang Pauli Institut, Wien, Austria), Konstantinos Politis (National Technical University of Athens, Greece) IC/CT2582/041

In the study of wave propagation over distances much longer than the typical wavelength phase-space methods are often used, i.e. spectral densities are used as a homogenized representation of the wavefield, and kinetic equations are constructed for their evolution.
The Wigner Transform (WT) is a nonlinear, nonparametric spectral density, first introduced by E. Wigner in 1932 in the context of quantum mechanics. In the last ten years it has been extensively used in the formulation of phase-space models for a variety of problems, such as geometrical optics limits, periodic problems, nonlinear and/or random waves. Physical areas of application include semiconductors, linear and nonlinear optics, water waves and more.
However, the WT features counterintuitive interference components, which make computation and interpretation problematic. To face this, variants such as Wigner measures or Wigner spectra are typically used in practice.
We use smoothed Wigner Transforms (SWT) to study wave propagation. We present the derivation of new, to the best of our knowledge, exact equations of motion for the SWT covering a broad class of wave propagation problems. As a special case we get exact equations of motion for spectrograms of wave fields. These are typically pseudodifferential (i.e. integrodifferential) in leading order.
Finally, we use the new equations to build a numerical technique for computing on caustics Ű as opposed to before and after, but not really on, caustics, that the existing Wigner measures methods work for. We present some case studies; the results from our method are in very good agreement with full solutions of the corresponding problems.

Helmholtz equation outside an open arc in a plane with a mixed boundary condition. **Valentina Kolybasova** (Lomonosov Moscow State University, Russian Federation), Pavel Krutitskii (Keldysh Institute of Applied Mathematics RAS, Russian Federation) IC/CT3405/042

A boundary value problem for the Helmholtz equation

$$\Delta u - k^2 u = 0, \quad k = \operatorname{Re} k > 0$$

outside an open arc in a plane is studied with mixed boundary conditions. In doing so, the Dirichlet condition is specified on one side of the open arc and the boundary condition of the third kind is specified on the other side of the open arc. We consider non-propagative Helmholtz equation, real-valued solutions of which satisfy maximum principle. By using the potential theory the boundary value problem is reduced to a system of singular integral equations with additional conditions. By regularization and subsequent transformations, this system is reduced to a vector Fredholm equation of the second kind and index zero. It is proved that the obtained vector Fredholm equation is uniquely solvable. Therefore the integral representation for a solution of the original boundary value problem is obtained. The computational methods for finding the numerical solution are discussed.

Global spatial regularity of solutions of an elasto-viscoplastic model. **Dorothee Knees** (Weierstraß-Institut Berlin, Germany) IC/CT1291/042

We present a global spatial regularity result for the displacements u, stresses σ and inner variables z of a quasi-static model from elasto-viscoplasticity. The model under consideration reads as follows for a domain Ω and a time interval $S = (0, T)$:

$$\operatorname{div}\sigma(t) + f(t) = 0\,, \quad \sigma(t) = A(\varepsilon(u(t)) - Bz(t))\,, \quad \partial_t z(t) = g(\sigma(t), \varepsilon(u(t)), z(t))$$

together with an initial condition for z and Dirichlet- and Neumann-conditions on $\partial\Omega$. Here, A denotes the elasticity tensor and B is a linear mapping which maps the internal variable z on the inelastic strain. The function g is a constitutive function which is assumed to be Lipschitz-continuous. For example, models of this type result from the Yosida-approximation of elasto-plastic models with linear hardening.

Under suitable assumptions on the data, this system has a weak solution $u \in L^p(S; H^1(\Omega))$ and $z \in W^{1,p}(S; L^2(\Omega))$ for some $p \in [1, \infty]$. Our main result is the following: if the domain and the data are smooth enough, then the weak solutions have the global spatial regularity $u \in L^p(S; H^2(\Omega))$ and $z \in W^{1,p}(S; H^1(\Omega))$. This theorem is proved with a difference quotient technique. We discuss furthermore, in which way results for nonsmooth domains can be achieved from the results for smooth domains.

Cauchy problem for a higher-order Boussinesq equation. **Albert Erkip** (Sabanci University, Turkey), Nilay Duruk (Sabanci University, Turkey), Husnu Erbay (Isik Üniversitesi, Turkey) IC/CT1699/042

In this study we establish global well-posedness of the following Cauchy problem for a higher-order Boussinesq equation:

$u_{tt}-u_{xx}-u_{xxtt}+\beta u_{xxxxtt} = (g(u))_{xx}$, $x \in \mathbb{R}$, $t > 0$, $u(x,0) = \phi(x)$, $u(x,0) = \psi(x)$

where β is a positive constant, $u(x,t)$ is a real-valued function of two real variables and $g(u)$ is a given function of u with $g(u) = 0$.

At the microscopic level the higher order Boussinesq equation was derived[1] for the longitudinal vibrations of a dense lattice, in which a unit length of the lattice contains a large number of lattice points. Thus, in the above higher-order Boussinesq equation which has been written in terms of the scaled variables, $u = u(x,t)$ is the longitudinal strain, t is time and x is a spatial coordinate along the length of the lattice. The same equation may also be derived at the macroscopic level using the continuum mechanics approach, in particular the nonlocal elasticity theory that includes the effect of long range interatomic forces.

We first establish[2] local well-posedness of the Cauchy problem in the Sobolev space H^s with any $s > 1/2$. The contraction mapping principle is used to prove the following theorem about the local existence and uniqueness of the Cauchy problem:

Theorem *Assume that* $s > \frac{1}{2}, \phi \in H^s, \psi \in H^s$ *and* $g \in C^{[s]+1}(R)$ *with* $g(u) = 0$, *then there is some* $T > 0$ *such that the above Cauchy problem has a unique local solution* $u \in C^2([0,T], H^s)$.

Next we prove the following result about global existence:

Theorem *Let conditions of the first theorem hold with* $s \geq 1$. *Assume further that* ψ *is the derivative of some* L^2 *function and* $G(u) = \int_0^u g(s)\,ds \geq 0$ *for all* $u \in \mathbb{R}$. *Then the above Cauchy problem has a unique global solution* $u \in C^2([0,\infty), H^s)$.

Stability of the moving boundary in a non-equilibrium shrinking unreacted core model with fast reaction for the sphere. **Adrian Muntean** (Universität Bremen, Germany) IC/CT2801/045

Many reaction-diffusion scenarios taking place in unsaturated reactive porous materials involve the formation and propagation of moving-sharp interfaces, where fast chemical reactions are assumed to be concentrated. When spatially separated reactants meet, the separation boundary may be assumed as sharp provided that the characteristic time scale of reaction is much smaller than that of transport. We illustrate the shrinking core setting by means of a moving-boundary system with kinetic condition modeling the driving force. We employ this formulation in order to study the evolution of the reaction front in a sphere made of partially wet porous material. The model relies on the idea that the reaction might be considered to be localized on a sharp interface. It consists of a set of semi-linear mass-balance equations coupled with a non-linear ordinary differential equation, which accounts for the motion of the interface. We refer to this differential equation driving the sharp-reaction interface into the material as the *kinetic (non-equilibrium) condition*. The model equations are non-linearly coupled by the *a priori* unknown position of the moving-reaction interface and non-linearities in the production terms. We present results on the well-posedness of the model and discuss the practical relevance of some of the estimates. Special attention is granted to the stability of the interface position with respect to alterations in the model parameters.

Existence of solutions for an eigenvalue problem with weight. **Siham El Habib** (University Mohamed I, faculty of sciences, Oujda, Morocco), Najib Tsouli (Université Mohammed Premier Oujda, Morocco) IC/CT869/015

In this work we study the existence of solutions for the eigenvalue problem $\Delta_p^2 u = \lambda m(x)|u|^{p-2}u$, $u \in W^{2,p}(\Omega)$ in a bounded smooth domain Ω, with Neumann boundary condition $\frac{\partial u}{\partial \nu} = 0$ on $\partial\Omega$, and where $m \in L^r(\Omega)$, $m \neq 0$ is a weight function which can change its sign, with $r = r(N,p)$ satisfying the conditions: $r > \frac{N}{2p}$ for $\frac{N}{p} \geq 2$ and $r = 1$ for $\frac{N}{p} < 2$.

On the mathematical models of the shock between a viscoelastic bar and a body. **Arpad Takacsi** (Univerzitet u Novum Sadu, Yugoslavia) IC/CT722/015

In the paper by Bergounioux, M., Long, N.T., Dinh, A.P.N., *Mathematical model for a shock problem involving a linear viscoelastic bar*, Nonlinear Analysis, Theory, Methods & Applications, Vol. 43, 547–561, 2001, the authors introduced and analyzed mathematical models of the shock between a body and a viscoelastic bar. In this presentation, applying the Mikusiński operator calculus we obtain an ordinary differential equation in the operator field, $\mathcal{F}$, and then solving it obtain the exact and the approximate solution in $\mathcal{F}$. The classical exact and approximate solutions are obtained by inverting the previously obtained operator ones.

Crystal dissolution and precipitation in porous media: variable pore geometry and upscaled model. **Tycho Van Noorden** (Technische Universiteit Eindhoven, The Netherlands), Iuliu Sorin Pop (TU Eindhoven, The Netherlands) IC/CT2524/045

In this work we propose a pore scale model for crystal dissolution and precipitation in a porous medium. Using this model we derive a macroscopic model using a formal homogenization procedure. Our investigations are motivated by the work of P. Knabner et al. (*Adv. Water Res.* 1995) and C.J. van Duijn et al. (*J. reine angew. Math.* 2004).

We consider a porous medium that is fully saturated by a fluid in which cations (e.g. sodium ions) and anions (e.g. chlorine ions) are dissolved. In a precipitation reaction, n cations and m anions can precipitate in the form of one particle of crystalline solid (e.g. sodium chloride) attached to the surface of the grains (the porous matrix). The reverse reaction of dissolution is also possible. As a result of the precipitation and dissolution of crystals the geometry of the flow domain may change.

The model we propose consists of a system of coupled partial

differential equations on a variable domain. The changes in the flow domain, which occur due to the dissolution and precipitation of crystals are modeled by a one phase Stefan-like free boundary condition. This describes the movement of the interface between the fluid and the crystal layer.

For simple geometries we show that solutions of the pore scale model exist and we study their qualitative behavior using both analytic and numerical techniques. In addition we present a numerical study of the macroscopic model.

On some nonlinear elliptic problems with an unknown measure data. **Juan Francisco Padial** (Universidad Politécnica de Madrid, Spain) IC/CT4423/045

We introduce a new type of nonlinear elliptic problems

$$\mathcal{A}(u) = \mu(\cdot, u) \quad \text{and} \quad <\mu(\cdot,u), \varphi> = \int_{\partial u^{-1}(\{1\})} \varphi(y) q(y) dH_{N-1}(y)$$

for all $\varphi \in C(\bar{\Omega}) \cap V$ and where V is a reflexive Banach space, $\mathcal{A}$ is a pseudo monotone, coercive bounded operator from V into V^*, q is a positive continuous function on $\bar{\Omega}$ (Ω is a bounded open subset of $\mathbb{R}^N$, $N \geq 2$) and H_{N-1} is the $N-1$ dimensional Hausdorff measure. In constrast with the usual elliptic problems, the Radon measure μ is an unknown of the problem depending on the solution u. A particular cases of this type problems can be understood as a particular case of the *Bernoulli problem*: to look for a function $u : \Omega \subset \mathbb{R}^N \to \mathbb{R}$ and a subset $B \subset \mathbb{R}^N$ such that $-\Delta u = 0$ in $\Omega \setminus B$, $u = 0$ on $\partial\Omega$, $u = 1$ on $\partial\Omega$ and $\frac{\partial u}{\partial n} = q$ on ∂B. We will study the existence (by ussing the Ambrosetti–Rabinowitz maontain pass lemma) and non existence and the uniqueness of solutions for the cases described before (Díaz, Padial and Rakotoson, On some Bernouilli free boundary type problems for general elliptic operators. *To appear* in The Royal Society of Edinburgh Proceedings A (Mathematics)).

Blow-up results for fractional differential equations. **Mokhtar Kirane** (Université de La Rochelle, France) IC/CT4465/004

Blow-up results are presented for systems of fractional differential equations with cross-diffusion terms in space and time.

A new family of schemes for kinematic flows with discontinuous flux. **Raimund Bürger** (Universidad de Concepción, Chile) IC/CT971/046

In engineering applications, multiphase flows of suspensions and emulsions are frequently approximated by spatially one-dimensional kinematic models, in which the velocity of each species of the disperse phase is a given function of the vector of concentrations of all species. The continuity equations then form a system of conservation laws, which describes the spatial segregation of species. This class of models also includes multi-class traffic flow, where vehicles belong to different classes according to their preferential velocities. Recently, these models were extended to fluxes that depend discontinuously on the spatial coordinate. This situation appears, for example, in clarifier-thickener models and in traffic flow with variable road surface conditions.

This paper presents a new family of numerical schemes for such kinematic flows with a discontinuous flux. It is shown how a very simple scheme for the scalar case, which is adapted to the "concentration times velocity" structure of the flux, can be extended to kinematic models with a velocity that changes sign, flows with two or more species (the system case), and discontinuous fluxes. In addition, a standard MUSCL-type upgrade can be devised to attain second order accuracy. It is proved that system variants of the scheme preserve an invariant region of admissible concentration vectors, provided that all velocities have the same sign. Moreover, for a multiplicative flux discontinuity, it is proved that scalar versions converge to a BV_t entropy solution of the model. In the latter case, the compactness proof involves a novel uniform but local estimate of the spatial total variation of the approximate solutions.

Numerical examples all variants within the new family of schemes applied to abstract examplesand problems of sedimentation, traffic flow, and the settling of oil-in-water emulsions.

This presentation is based on joint work with A. García, K.H. Karlsen and J.D. Towers.

Entropy behaviour of evolution PDEs. **Phil Broadbridge** (AMSI, Australia) IC/CT4255/046

The concepts of entropy and of irreversibility can be introduced in a self-consistent manner and at an elementary level by reference to some simple evolution equations such as the linear heat equation. Given an evolving probability distribution p(x,t), the Shannon entropy is the expected value of log (1/p). This must increase monotonically if p(x,t) represents a thermodynamic process. In turn, this is equivalent to the density $p\ log(1/p)$ having a non-negative source term. This is easily seen to be true when p(x,t) satisfies a general nonlinear 2nd order diffusion equation.

When we consider fourth order diffusion terms, new problems arise. The fourth order equation $p_t = -p_{xxxx}$ is irreversible because the evolution operator is self adjoint with negative spectrum and therefore the locally defined density p^2 has a source term that is negative. However, the source term of -$p\ log|p|$ can take either sign. We know from applications such as thin film flow, and surface diffusion on metals, that fourth order diffusion terms always generate ripples rather than a monotonic approach to equilibrium. Despite this, we can construct a non-trivial class of fourth order quasilinear diffusion equations that increase the Shannon entropy and maintain positivity.

Similarity reductions of a nonlinear model for vibrations of beams. **Maria Santos Bruzon** (Universidad de Cádiz, Spain) IC/CT3435/046

The application of Lie transformations group theory for the construction of solutions of nonlinear partial differential equations is one of the most active fields of research in the theory of nonlinear partial differential equations and applications.

Motivated by the fact that symmetry reductions for many PDEs are know that are not obtained by using the classical symmetries, there have been several generalizations of the classical Lie group method for symmetry reductions. The notion of nonclassical symmetries was firstly introduced by Bluman and Cole to study the symmetry reductions of the heat equation. Clarkson and Mansfield proposed an algorithm for calculating the determining equations associated with the nonclassical method.

Symmetries and reductions technique are applied to a mathematical model which describe the vibrations of a beam.

Occurrence of a δ-shock in nonlinear chromatography. **Marco Mazzotti** (ETH Zürich, Switzerland) IC/CT1360/046

The local equilibrium model of two-component nonlinear chromatography consists of the following two first order partial differential mass balance equations (conservation laws): $u_t + f_t(u,v) + u_x = 0$ and $v_t + g_t(u,v) + v_x = 0$, where u and v are the concentrations of the species to be separated, and t and x are time and space. The solution for a Riemann problem (constant initial state in the column, and constant feed composition) consists of constant composition states separated by transitions, i.e. concentration fronts. The latter can be continuous simple waves that fulfill the partial differential equations or discontinuous shocks that fulfill the so called Rankine-Hugoniot condition, where no mass accumulation on the shock front is assumed.

We study the solution of Riemann problems, where adsorption of the two species is characterized by the following functions f and g defining the so called adsorption isotherms: $f(u,v) = au/(1-u+v)$ and $g(u,v) = bv/(1-u+v)$, where b and a, with $b > a$, are constant. In this case the model equations are of a mixed type, i.e. they are hyperbolic in a region of the composition space and elliptic in the remaining part of it.

It is shown that for some Riemann problems in the hyperbolic region the solution is not constituted of constant states separated by simple waves and shocks only. In these cases the Rankine-Hugoniot condition, that implies the conservation of mass through the shock with no accumulation on the shock itself, cannot be fulfilled. The solution can accommodate the excess mass only by admitting material accumulation on the shock, thus generating a spike that grows while traveling on top of the shock discontinuity along the column. Mathematically, this is a Dirac-delta, which in this context is called delta-shock.

On adaptive HRSC techniques for multi-class traffic flow problems. **Rosa Donat** (Universitat de València, Spain), Pep Mulet (Universitat de València, Spain) IC/CT2228/004

Multi-class traffic flow problems can be modeled as hyperbolic systems of conservations laws. The characteristic structure of these systems is seldom known, thus posing significant difficulties to schemes based on approximate Riemann solvers.

There has been recent interest in the application of "solverless" high resolution shock capturing (HRSC) schemes, such as those based on non-characteristic WENO (cf. [Zhang,Wong,Shu] and references therein), for which only an estimate of the maximum wave speed is needed. Results comparable to those obtained with monotone first-order schemes, such as Lax-Friedrichs, can be obtained with much coarser grids, and adaptive techniques can be used to lower the computational cost of the simulation (cf. [Burger,Kodacevicius]).

We present HRSC schemes that incorporate more characteristic information, together with an Adaptive-Mesh Refinement technique specifically designed for finite-differences WENO-like techniques. The fine resolution simulations one can achieve with the combination of these two techniques, show that there can be substantial differences between a non-characteristic scheme versus a characteristic-based scheme.

Numerical solutions of population-balance models in particulate systems. **Shamsul Qamar** (Universität Magdeburg, Germany) IC/CT843/046

This work focuses on the derivation of numerical schemes for solving population balance models (PBMs) with simultaneous nucleation, growth and aggregation processes. The population balance equation is considered to be a statement of continuity. It tracks the change in particle size distribution as particles are born, die, grow or leave a given control volume. In the population balance models the one independent variable represents the time, the other(s) are *property coordinate(s)*; e.g., the particle size in the present case. They typically describe the temporal evolution of the number density functions and have been used to model various processes. These include crystallization, polymerization, emulsion and cell dynamics.

Two numerical methods are proposed for this purpose. The first method combines a method of characteristics (MOC) for growth process with a finite volume scheme (FVS) for aggregation processes. For handling nucleation terms, a cell of nuclei size is added at a given time level. The second method purely uses a semidiscrete finite volume scheme for nucleation, growth and aggregation of particles. Note that both schemes use the same finite volume scheme for aggregation processes. On one hand, the method of characteristics offers a technique which is in general a powerful tool for solving linear growth processes, has the capability to overcome numerical diffusion and dispersion, is computationally efficient, as well as give highly resolved solutions. On the other hand, the finite volume schemes which were derived for a general system in divergence form, are applicable to any grid to control resolution, and are also computationally not expensive.

In the first method a combination of finite volume scheme and the method of characteristics gives a highly accurate and efficient scheme for simultaneous nucleation, growth and aggregation processes. The second method demonstrates the applicability, generality, robustness and efficiency of high resolution schemes. The numerical test cases show clear advantages of the current schemes for the solution of population balances.

Symmetry analysis for a thin film type equation. **Maria Luz Gandarias** (Universidad de Cádiz, Spain) IC/CT1046/046

We consider the one-dimensional version of

$$u_t = -\nabla.(f(u)\nabla.(\Delta u)) - k\nabla.(g(u).(\nabla u)) = 0\,,$$

where u stands for the thickness of the film and f and g depends on the geometry of the problem. Such equations have been used to model the dynamics of a thin film of viscous liquid. The one dimensional equation

$$u_t = -(f(u)u_{xxx})_x - k(g(u)u_x)_x$$

applies if the liquid film is uniform in one direction. We analyze this equation by means of the theory of symmetry reductions of partial differential equations. It is found that some similarity solutions are solutions with physical interest.

Criterium for the gradient catastrophe for the non-isentropic gas dynamics equations. **Olga Rozanova** (Moscow State University, Russian Federation) IC/CT485/046

It is well known that the solutions of the systems of gas dynamics equations, being smooth initially, can lose the initial smoothness within a finite time (this phenomenon is called the gradient catastrophe. However, the sufficient and necessary conditions for the gradient catastrophe in the terms of initial data were known only for the isentropic one-dimensional flow, where one can write the system of two quasi-linear equations in the Riemannian invariants and then apply the method of char-

acteristics. In the non-isentropic case this criterium of such kind were known even for one space dimension. Nevertheless, some particular results are obtained, as usual, they concerns only sufficient conditions of the loss of smoothness (Sideris, Pokhozhaev).

We propose the method to describe the motion by means of integral functionals, which are actually integrals of the solution components over a material volume. Included among the functionals are the kinetic and potential energies, impulse, momentum of mass, and a number of specific integrals. These integral functionals are functions of time and satisfy a system of ODE, which is closed provided we consider a velocity field, linear inside of an infinitesimal material volume. Further, the problem about the data resulting the gradient catastrophe can be reduced to the problem of blow-up in a system of ODE for n^2 functions (which are derivatives of velocity), where n is the dimension of space. For $n = 1$ this system of ODE consists of one equation and can be investigated completely, therefore the criterium of the gradient catastrophe can be obtained. Moreover, the method gives a possibility to determine the place of arising singularity.

The theory of δ- and δ'-shock wave type solutions to systems of conservation laws and the transportation and concentration processes. **Vladimir Shelkovich** (Saint Petersburg State University, Russian Federation) IC/CT427/046

There are *nonclassical* situations when systems of conservation laws admit δ- and δ'-shock type solutions. δ-Shock (δ'-shock) is a singular solution such that its components may contain the Dirac delta functions (the Dirac delta function and their derivatives). For the theory of δ-shocks see [1], [3], [4] and the references therein. An absolutely new theory of δ'-shocks was established in [5], [6].

1. By using [1], [3], [4], we describe the dynamics of propagation and interaction of δ-shock fronts in multidimensional zero-pressure gas dynamics in conservative form

$$\rho_t + \nabla \cdot (\rho U) = 0, \quad (\rho U)_t + \nabla \cdot (\rho U \otimes U) = 0,$$

non-conservative form

$$\rho_t + \nabla \cdot (\rho U) = 0, \quad U_t + (U \cdot \nabla) U = 0,$$

relativistic form

$$\rho_t + \nabla \cdot (\rho C(U)) = 0, \quad (\rho U)_t + \nabla \cdot (\rho U \otimes C(U)) = 0,$$

where $C(U) = \frac{c_0 U}{\sqrt{c_0^2 + |U|^2}}$, c_0 is the speed of light.

2. In the framework of the problems **1.** we derive δ-shock balance relations connected with mass and momentum transportation (from a volume into a singular surface).

We construct δ-shock wave type solution of the Cauchy problem for zero-pressure gas dynamics, describing the dimensional bifurcations of the singular support of this solution from $(n-1)$-dimensional surface into a point. These results can be used for description of transportation and concentration processes and may lead to discovery of new physical effects in cosmology.

3. For the system

$$u_t + (f(u))_x = 0, \quad v_t + (f_1(u)v)_x = 0, \quad w_t + (f_{22}(u)v^2 + f_{21}(u)w)_x = 0,$$

the Cauchy problems admitting δ'-shock is solved, where $f(u)$, $f_1(u)$, $f_{21}(u)$, $f_{22}(u)$ are smooth functions.

In order to deal with singular problems **1.**-**3.** the *weak asymptotics method* [2]–[4] is used.

On a numerical solution of the Cauchy problem for the Laplace equation by the fundamental solutions method. **Takashi Ohe** (Okayama University of Science, Japan), Kohzaburo Ohnaka (Osaka university, Japan), Katsu Yamatani (Meijo University, Japan) IC/CT2929/047

Let Ω be an annular domain $\{\mathbf{x} \mid 0 < \rho_1 < |\mathbf{x}| < \rho_2\} \subset \mathbb{R}^2$, and $\Gamma_\Theta \equiv \{\mathbf{x} = (\rho_2 \cos\theta, \rho_2 \sin\theta), 0 \le \theta \le \Theta\}$ be a connected part of the outer boundary of Ω, where $0 < \Theta \le 2\pi$. Suppose f and g be analytic functions defined on Γ_Θ. We consider a numerical approximation method for the solution of a Cauchy problem for the Laplace equation $\Delta u = 0$ in Ω with Cauchy conditions $u = f$ and $\partial u/\partial r = g$ on Γ_Θ.

The Cauchy problem for the Laplace equation is known as an ill-posed problem and difficult to obtain a proper numerical solution. Many researchers studied a numerical method for the problem by various approaches, for example, based on the finite difference method, and the finite element method. Hon and Wei (2003) studied a method based on the fundamental solutions method for the case that the domain Ω is a disk, however, they did not consider the case of an annular domain.

In this talk, we investigate a numerical method based on the fundamental solutions method for an annular domain. For the case that Γ_Θ is the whole of the outer boundary, i.e. $\Theta = 2\pi$, we have proposed a method using 'inner' and 'outer' fictitious charges, and have shown some theoretical analysis on the uniqueness and convergence of the numerical solutions [Ohe and Ohnaka(2004)]. We develop our method for the case where Γ_Θ is a part of the outer boundary, i.e. $\Theta < 2\pi$, and investigate convergence and stability properties using numerical experiments.

On a boundary-value problem for the differential equation of second order with discontinuous coefficients. **Rizvan Pashayev** (Baku State University, Azerbaijan) IC/CT4170/050

Consider the boundary-value problem

$$-y'' + q(x)y = \lambda^2 \rho(x) y, \quad 0 < x < +\infty, \quad \text{with } y(0) = 0, \tag{1}$$

where the function $q(x)$ is real-valued and satisfies the condition $\int_0^\infty x\,|q(x)|\,dx < +\infty$, and $\rho(x)$ is a piecewise constant function

$$\rho(x) = \begin{cases} 1 & \text{for } a_2 \le x < +\infty, \\ \alpha_2^2 & \text{for } a_1 \le x < a_2, \\ \alpha_1^2 & \text{for } 0 \le x < a_1. \end{cases}$$

In the case of $\alpha_1 = \alpha_2 = 1$ (i.e., when $\rho(E) \equiv 1$), the inverse problem of scattering theory for this boundary-value problem was completely solved by V.A. Marchenko (1955). When $0 <$

$\alpha_1 = \alpha_2 \neq 1$ this problem was first studied by M.G. Gasymov (1977), but complete solution of the inverse scattering problem was obtained by I.M. Guseinov and R.T. Pashayev (2002). It turns out that having a discontinuity in the function $\rho(x)$ considerably influences the structure of representation of the lost solutions, and the main equation of the inverse problem.

In this talk we study the inverse problem of scattering theory for this boundary-value problem, in the range where $\alpha_i > 0$ but $\alpha_i \neq 1$ for each of $i = 1, 2$, and where $\alpha_1 \neq \alpha_2$.

Modified Landweber iterations in a multilevel setting applied to the determination of nonlinear material parameters in piezoelectricity. **Tom Lahmer** (Universität Erlangen–Nürnberg, Germany), Barbara Kaltenbacher (Universität Stuttgart, Germany) IC/CT1538/047

An efficient solution of the inverse problem of identifying nonlinear dependencies in hyperbolic systems of PDEs, here piezoelectric material parameter curves, is the aim of this work. The dominant material tensor entries in the coupled field equations which describe the electromechanical interplay are approximated by functions depending on the physical field quantities electric field or mechanical stress. In order to solve this nonlinear and ill-posed problem of parameter curve identification efficiently, modified Landweber iterations (steepest descent and minimal error) will be studied. A multilevel approach is expedient due to the discretization of the unknown parameter curves and high computational efforts solving the forward problem (transient, nonlinear FEM computations). Theoretical investigations concerning convergence and regularization properties of the methods in a multilevel scenario will be presented, along with numerical results from an example in piezoelectricity.

A sampling method for electromagnetic scattering in a half-space. **Christoph Schneider** (Universität Mainz, Germany), Martin Hanke (Universität Mainz, Germany), Bastian Gebauer (RICAM Linz, Austria) IC/CT2705/047

We consider a simple (though fully three-dimensional) mathematical model for the electromagnetic exploration of buried, perfectly electrically conducting objects within soil underground. We assume to have two homogeneous half spaces $\mathbb{R}^3_+$, $\mathbb{R}^3_-$ connected by a flat interface Σ_0. We apply AC voltage of a fixed low frequency of some kHz to coils positioned on a sheet S parallel to the interface at constant height. Thereby we generate a time-harmonic electromagnetic field and measure the voltage which is induced within these coils due to the electromagnetic field. However, we take the voltage induced by the scattered field not the total field. The scattered field is the field scattered by the perfect conducting objects Ω, while the total field is the scattered field added to the field generated by the coils. We assume that the objects are completely buried in the soil (i.e. $\overline{\Omega} \subset \mathbb{R}^3_-$). Further on the complement of Ω within the soil is supposed to be simply connected. The factorization method applied to the underlying mathematics leads to a product of three operators $M = LFL^T$. M maps the voltages applied to the coils on the sheet S to measurements of the induced voltages due to the scattered field in these coils. The operators L and L^T are transposed operators. They map the voltages applied to the coils on the sheet to the electromagnetic field on the boundary of the scatterer and vice versa. Furthermore F represents a certain diffraction of the field at the boundary of the scatterer. This factorization justifies a sampling method for whether a point of interest is located inside a buried scatterer. Unfortunately, our data do not suffice completely to characterize Ω using the given range of M. However, we can characterize a subset Ω_1 of Ω and obtain an approximate image of the buried object(s).

Numerical procedures for the determination of the leading coefficient $a(x)$. **Hossein Azari** (Shahid Beheshti University, Iran) IC/CT4064/047

The aim of this talk is to study the parabolic inverse problem of determination of the leading coefficient in the heat equation with an extra condition at the terminal. After introducing a new variable, we reformulate the problem as a nonclassical parabolic equation along with the initial and boundary conditions. The uniqueness and continuous dependence of the solution upon the data are demonstrated, and then finite difference methods, backward Euler and Crank–Nicolson schemes are studied. It is proved that both numerical schemes are stable and convergent to the real solution. The results of some numerical examples are presented, which demonstrate the efficiency and rapid convergence of the methods.

Balancing principle for solving naturally linearized elliptic Cauchy problem. **Hui Cao** (RICAM Linz, Austria) IC/CT512/047

A classical ill-posed problem elliptic Cauchy problem is considered. By natural linearization we transform elliptic Cauchy problem into linear ill-posed operator equation. Discretization is applied as a regularization method (also known as self-regularization) to obtain a stable approximate solution. Balancing principle as an adaptive strategy is studied to choose appropriate discretization level. Numerical tests illustrate the theoretical results.

Adaptive choice of regularization parameter for nonlinear statistical inverse problems . **Mihaela Pricop** (Universität Göttingen, Romania), Thorsten Hohage (Universität Göttingen, Germany) IC/CT813/047

In this talk we consider statistical inverse problems described by nonlinear operator equations $F(a) = u$ where a is an element of a Hilbert space and u is an L^2-function. We construct an estimator $\hat{a}_n$ of a from measurements of u perturbed by random noise using nonlinear Tikhonov regularization in a Hilbert scale setting. For a-priori parameter choice strategy order-optimal rates of convergence for the mean-integrated square error $\mathbf{E}\|\hat{a}_n - a\|^2$ have already been obtained, but an a-posteriori parameter choice was not available in our setting. As the discrepancy principle is not applicable since we are dealing with stochastic noise, we develop an adaptive regularization parameter rule starting from the Lepskii principle which proves to have order-optimal MISE. Applications to parameter identification problems for elliptic differential equations are also given.

The multi-dimensional refinement indicators algorithm for optimal parametrization. **Hend Ben Ameur** (University of Tunis, Tunisia) IC/CT1300/047

The estimation of distributed parameters in partial differential equations (PDE) from measures of the solution of the PDE may lead to under-determination problems. The choice of a parameterization is a usual way of adding a-priori information by reducing the number of unknowns according to the physics of the problem. The refinement indicators algorithm provides a fruitful adaptive parameterization technique that parsimoniously opens the degrees of freedom in an iterative way. We present a *new general form of the refinement indicators algorithm* that is applicable to the *estimation of multi-dimensional parameters* in any PDE. In the linear case, we state the relationship between the refinement indicator and the decrease of the usual least-squares data misfit objective function. We give numerical results in the simple case of the identity model, and this application reveals the *refinement indicators algorithm as an image segmentation technique*.

Stationary transport equations: the case of continuous spectrum. **Illya Karabash** (Donetsk, Ukraine) IC/CT902/048

We consider the abstract kinetic equation $d\psi/dx = -JL\psi$, $x \in [0,\infty]$, in a Hilbert space H. It is supposed that $J = J^* = J^{-1}$, $L = L^* \geq 0$, $\ker L = 0$. The following theorem is proved: if JL is similar to a self-adjoint operator, then an associated boundary problem has a unique solution. We apply this theorem to the stationary equation of Brownian motion and the stationary Kolmogorov-Chapman equation.

Scattering for open quantum systems. **Mark Malamud** (Donetsk, Ukraine) IC/CT926/048

We will discuss applications of new results on scattering matrices and dilations of maximal dissipative operators to some open quantum systems. In particular, we consider an application to a quantum transmitting Schrödinger–Poisson system (cf.[1]).

A main ingredient of our talk is a new formula for scattering matrix $S(\lambda)$ of a scattering system $\{L, L_0\}$ where $L_0 = A_0 \oplus T_0$ describes a situation where both subsystems corresponding to the operators $A_0 = A_0^*$ and $T_0 = T_0^*$ do not interact while $L = L^*$ takes into account an interaction of the subsystems.

In the case of transmitting Schrödinger–Poisson system we find a formula for scattering matrix $\{S(\lambda)\}$ of a scattering system $\{L, L_0\}$ by means of the corresponding Weyl functions on half-lines and discuss its connection with characteristic functions of a family of maximal dissipative extensions corresponding to transparent boundary conditions. Moreover, we show that under some natural assumptions a transmitting Schrödinger–Poisson system is uniquely determined by the scattering matrix mentioned above.

Our considerations are partially based on uniqueness results for Dirac type and matrix Sturm–Liouville operators (see [2,3]) as well as on some recent results on absolutely continuous and singular spectrum of self-adjoint extensions of symmetric operators[4] and on coupling method for construction of generalized resolvents from[5].

Chebyshev expansion for the eigenfunctions of the almost-Mathieu operator. **Jesus Abderraman** (Univ. Politécnica de Madrid, Spain) IC/CT3621/048

Quasiperiodic super-lattices are widely used in nanotechnology. Their spectrum is often associated with one-dimensional Schrödinger operators - with ergodic potential unity. The Almost Mathieu operator [1] is a typical example. A difference equation related to this operator is Harper's:

$$\Psi_{n+1} + 2\lambda\cos(2\pi n\theta + \nu)\Psi_n + \Psi_{n-1} = \varepsilon\Psi_n.$$

Here, the Ψ_n's are energy eigenfunctions and λ is a real parameter. For integer θ, the eigenfunctions $\Psi_n = U_n(\frac{\varepsilon}{2} - \lambda\cos(\nu))$ are easily obtained: the $U_n(x)$ are Chebyshev polynomials of second kind. The spectrum has one band in the compact range $[-2+2\lambda\cos(\nu), 2+2\lambda\cos(\nu)]$. When $\theta = \frac{p}{q}$ is rational the spectrum has exactly q bands. For irrational θ, the ergodic case, the spectrum is amazing and very complicated. There has been a lot of work on this spectrum [2]. The eigenfunctions have solutions in form of determinants of sections of the Jacobi matrix associated with Harper's equation. By certain gauge invariance properties of Schrödinger's operator, it is enough to study the case $-1 \leq \lambda \leq 1$. Due to ergodicity, the spectrum is independent of ν. In a first analysis, take $\nu = 0$. Harper's equation is then

$$\Psi_{n+1} + 2\lambda T_n(\cos(2\pi\theta))\Psi_n + \Psi_{n-1} = \varepsilon\Psi_n.$$

To solve this equation, eigenfunctions are not expanded in powers of ε, but in a series in $T_n(\cos(2\pi\theta))$. The dependency on ε and λ is transferred to the coefficients of the expansion. This allows us to analyze some properties of Ψ_n solutions for $n \to \infty$.

On fractional Fourier transform of ultra-distributions. **Bharat Bhosale** (University of Mumbai, India) IC/CT54/015

The fractional Fourier analysis is used for investigations of fractal structures; which in turn are used to analyze different physical phenomena. For instance, it has got the applications in optical engineering, as has been discussed by Alieva and Barbe and many others.

In this paper, the fractional Fourier transform is extended to ultra-distributions of compact support. For this purpose, we considered the space $E\check{S}(M_p;K)$ of ultra-distributions of compact support on which fractional FT is transformable. Analogous results to that of Paley–Wiener theorems are obtained for ultra-differentiable functions and ultra-distributions in the context of the fractional FT. At the end indicated few applications showing its edge over the other transforms.

Boundary-value spaces and M-functions for non-selfadjoint operators. **Ian Wood** (University of Aberystwyth, UK) IC/CT2527/015

We develop an extension of abstract boundary value spaces from selfadjoint to non-selfadjoint operators. The starting point is an adjoint pair of operators A and $\widetilde{A}$ in a Hilbert space H which satisfy an abstract Green formula:

$$(\widetilde{A}^*u, v)_H - (u, A^*v)_H = (\Gamma_1 u, \widetilde{\Gamma}_2 v)_{\mathcal{H}} - (\Gamma_2 u, \widetilde{\Gamma}_1 v)_{\mathcal{K}}.$$

where $\mathcal{H}$ and $\mathcal{K}$ are abstract boundary spaces. Given $B \in \mathcal{L}(\mathcal{K}, \mathcal{H})$, the M-function (generalised Dirichlet to Neumann map) is defined by

$$M_B(\lambda) : \mathrm{Ran}\,(\Gamma_1 - B\Gamma_2) \to \mathcal{K},\ M_B(\lambda)(\Gamma_1 - B\Gamma_2)u = \Gamma_2 u \text{ for all } u \in \ker(\widetilde{A}^* - \lambda).$$

We then study the relationship between the M-function and spectral properties of realisations of $\widetilde{A}^*$. In particular, the results can be applied to elliptic operators.

Stability of vortices in 3D Bose–Einstein condensates. **Richard Kollár** (University of Michigan, Ann Arbor, Slovakia) IC/CT790/048

The structure of the nonlinear Schrödinger equation supports existence of topologically non-trivial vortex solutions. Their stability is studied by means of a very robust method – the Evans function. A traditional limitation of the Evans function technique is that it is generically an one-dimensional method and its extenstion to higher dimensions is very rare. In the case of the axi-symmetrical vortices in three-dimensional Bose-Einstein condensates we are able to extend this method by using information on Krein signature of eigenvalues.

04: Partial Differential Equations, Posters

IC/PP539/004: A combined Chebyshev polynomials and Sumudu transform for solving the neutron transport equation.

Presenter: Abdelouahab Kadem (Université Sétif, Algeria)

In this work, we present a new approximation for the one-group linear transport equation with anisotropic scattering in a slab, using Chebyshev polynomials. To this end, the angular flux is expanded in a truncated series of Chebyshev polynomials in the angular variable. Replacing this expression in the transport equation and taking moments like in the P_N method, leads to a new approximation. The resultant first-order linear differential system is solved for the spatial function coefficients by application of the Sumudu transform technique. The inversion of the transformed coefficients is performed also analytically, using Trzaska's method and the Heaviside technique.

IC/PP3980/040: Overlapping operator splitting methods and applications in stiff differential equations.

Presenter: Juergen Geiser (Humboldt-Universität zu Berlin, Germany)

We present the stability of an overlapping operator-splitting method based on overlapping iterative methods. We discuss the iterative Operator Splitting method in the context of decoupling the stiff and non-stiff operators with respect to overlap them. In the context of stabilization the stiff operators, we present the overlapping ideas as extension to the standard iterative operator splitting method. The efficiency of considering the overlapping method instead of the standard method is further discussed. We apply our theoretical results on model problems for stiff linear and nonlinear parabolic partial differential equations.

IC/PP4367/040: Behavior of solutions for a reaction–diffusion equation related to a model of crystal growth.

Presenter: Toshiko Ogiwara (Josai University, Japan)

We shall investigate a reaction–diffusion equation

$$u_t = u_{xx} + f(u), \quad x \in \mathbb{R}, \quad \text{for } t > 0,$$

where $f(u)$ is a periodic function with period 1. This is related to a mathematical model of crystal growth. Here the unknown function $u(x,t)$ represents the local height of the crystal surface and is normalized in order that 1 denotes the size of a unit molecule.

A solution $u(x,t)$ of this equation is called a *travelling wave* if it is written in the form $u(x,t) = \phi(x - ct)$ for some constant c and some function $\phi(y)$. Here we call the constant c the speed, and the function $\phi(y)$ the profile of the travelling wave.

We show that, for any $l > 0$, there exists a travelling wave $\phi(x - ct)$ with unbounded profile $\phi(y)$ satisfying

$$\phi(y - l) = \phi(y) + 1, \quad y \in \mathbb{R},$$

and consider the relation between the length l and the speed c. Furthermore, we study the asymptotic behavior of solutions with bounded initial data.

IC/PP4720/041: On the stability of damped Timoshenko systems: Cattaneo versus Fourier law.

Presenter: Hugo Danilo Fernandez Sare (Universität Konstanz, Germany)
Co-author: Reinhard Racke (Universität Konstanz, Germany)

We consider vibrating systems of hyperbolic Timoshenko type that are coupled to a heat equation modeling an expectedly dissipative effect through heat conduction. While exponential stability under the Fourier law of heat conduction holds, it turns out that the coupling via the Cattaneo law does not yield an exponentially stable system. This seems to be the first example that a removal of the paradox of infinite propagation speed inherent in Fourier's law by changing to the Cattaneo law causes a loss of the exponential stability property. Actually, for systems with history, the Fourier law keeps the exponential stability known for the pure Timoshenko system without heat conduction, but introducing the Cattaneo coupling even destroys this property.

IC/PP919/041: On the boundedness and compactness of a class of Fourier integral operators.

Presenter: Abderrahmane Senoussaoui (Université d'Oran Es-Sénia, Algeria)

We study the L^2-boundedness and L^2-compactness of a class of Fourier integral operators of types:

$$A\varphi(x) = \int_{\mathbb{R}^n} e^{iS(x,\theta)} a(x,\theta) \mathcal{F}\varphi(\theta)\, \mathrm{d}\theta\,,$$

in which appears two C^∞-functions, namely the phase function $S(x,\theta)$ and the amplitude a, and where $\mathcal{F}$ is the Fourier transformation.

These operators are bounded (respectively compact) if the weight of the amplitude is bounded (respectively tends to 0).

IC/PP1058/042: On some doubly nonlinear elliptic–parabolic equations in Banach spaces.

Presenter: Tomomi Kojo (Shibaura Institute of Technology, Japan)

We consider the IVP for some doubly nonlinear elliptic-parabolic equations of the form $d(Bu)/dt + Au = f$ in Banach spaces. Existence theorem of weak solutions for this equation is shown. Time discretization method is used to construct approximate solutions. Concerning the strong convergence of approximate solutions, we shall use a new type of compactness theorem.

IC/PP4048/043: Numerical solution for the diffusion equation subject to purely integral conditions.

Presenter: Souad Bensaid (University Centre Larbi Ben M'Hidi, Algeria)

In this paper, numerical schemes are developped for obtaining approximate solutions to the initial-boundary value problem for one-dimensional diffusion equation with purely integral conditions. These numerical schemes are based on the standard backward Euler method, the standard Crank-Nicholson method, a modified backward Euler method, and a modified Crank-Nicholson method. Some experimental numerical results using the proposed numerical procedure are discussed.

IC/PP4046/043: Galerkin method applied to parabolic problem with a nonlocal boundary condition.

Presenter: Abdelfatah Bouziani (University Centre Larbi Ben M'Hidi, Algeria)

The present paper is devoted to the investigation of a model parabolic mixed problem with boundary integral condition. Existence, uniqueness and continuous dependence upon data of a weak solution of this latter are proved by means of the Galerkin method.

IC/PP481/043: Boundary-value problem for higher-order parabolic evolution equations.

Presenter: Assia Guezane Lakoud (Annaba University, Algeria)
Co-author: Belakroum Dounia (University of Annaba, Algeria)

In this poster we will study a boundary value problem for higher order parabolic equations with unbounded operator coefficient in a Hilbert space. The proofs are based on *a priori* estimates. In appropriate functional spaces, we prove the existence, uniqueness and the continuous dependence of the strong solution to respect to data.

IC/PP4344/045: On a numerical scheme for the Willmore flow.

Presenter: Tomáš Oberhuber (Czech Technical University, Prague, Czech Republic)

The contribution deals with the Willmore flow which is described by the relaxation of a functional depending on the mean curvature of a curve or a surface. This problem comes from the physics of elasticity but there are also applications of the Willmore flow in image processing. We describe a numerical scheme based on the finite-difference method on a uniform grid. We deliver several qualitative examples of computation using the derived scheme as well as numerical studies of convergence demonstrating ability of the scheme.

IC/PP3127/046: Lie and conditional symmetries of systems of reaction–diffusion–convection equations.

Presenter: Roman Cherniha (National Academy of Sciences of Ukraine, Kyiv)

Systems of nonlinear reaction-diffusion-convection (RDC) equations of the form:

$$\bar{U}_t = (A(\bar{U})\bar{U}_x)_x + B(\bar{U})\bar{U}_x + \bar{C}(\bar{U})\,, \qquad (1)$$

where $\bar{U} = (U_1, U_2)$ is an unknown vector function, $\bar{C}(\bar{U}) = (C_1(\bar{U}), C_2(\bar{U}))$ is an arbitrary vector function, $A(\bar{U})$ and $B(\bar{U})$ are matrices 2×2 with the elements $a_{ij}(\bar{U})$ and $b_{ij}(\bar{U})$, $i,j = 1,2$ being arbitrary smooth functions, are considered. Systems of the form (1) describe a great number of various processes in physics, biology and chemistry. While there is no existing general theory for analytical integrating nonlinear RDC systems of the form (1), construction of particular exact solutions for these equations is a non-trivial and important problem. Finding exact solutions that have a physical, chemical or biological interpretation is of fundamental importance. Now the most powerful methods for construction of exact solutions to nonlinear RDC systems are the group-theoretical approaches.

Since a *complete description* of the Lie and conditional symmetries of system (1) is a very difficult problem in the general case, we present the recent results [1]-[5] obtained for several important subclasses of (1).

IC/PP1043/046: On bounded weak solutions of a degenerate parabolic equation.

Presenter: Young-Sam Kwon (American Mathematical Society, USA)

In this paper we consider bounded weak solutions u of a degenerate parabolic equation defined in a subset $(0,T)\times\Omega\subset\mathbb{R}^+\times\mathbb{R}^d$. We define a strong notion of trace at the boundary $(0,T)\times\partial\Omega$ reached by L^1 convergence for a large class of functionals of u. Those functionals depend on the flux function of the degenerate parabolic equation and on the boundary.

IC/PP4260/046: Strong trace for solutions of degenerate parabolic–hyperbolic equation.

Presenter: Young-Sam Kwon (American Mathematical Society, USA)

In this paper we show the existence of strong trace for entropy solutions of degenerate parabolic-hyperbolic equation on boundary of a bounded domain with smooth boundary.

IC/PP3075/047: On new analytical approach to some classes of mathematical physics inverse problems.

Presenter: Sharif Guseynov (Latvijas Universitate, Latvia)

The problems for partial differential equations are characterized by the main equation, the definition's domain, boundary and initial conditions. Therefore we can mark out coefficient, geometrical, boundary and evolutional inverse problems. In this paper we consider a some classes of non-homogeneous coefficient inverse heat transfer problems in the bounded domain under some additional information. In the coefficient inverse problems the coefficients of main equation and (or) or right-hand side are not known and have to be determined. Heat transfer inverse problems are manifold by appearances and forms of problems setting, by degree of incorrectness. Thus, these problems are suitable for approbation of the regularization theory methods and algorithms. The increase of interest in the solutions of these inverse problems is due to the needs of practices in connection with wide spread occurrence of non-stationary and nonlinear real heat-mass transfer processes. These effects require creation of the new mathematical approaches and methods (including analytical methods). The principal advantages of these methods are well known: they allow carrying out experimental researches, which are to the utmost zoomed-in to the real circumstances, or in time of the direct exploitation of technical objects. Determination of the thermal diffusivity is a rather challenging problem even for a homogeneous medium. We offer one simple analytical approach for determination of required coefficient of thermal conductivity under various type additional conditions. Offered approach lets reduce the initial inverse problem to the problem for the solution of the first kind Volterra linear integral equation. In the present work as example, we apply offered approach to steady-state inverse thermal conductivity problem. Let us note the offered method is suitable for solution of some classes of nonlinear direct and inverse problems of mathematical physics.

IC/PP3318/047: Inverse modelling: different methods.

Presenter: Evgeniy Tantserev (Universitetet i Oslo, Norway)

The transient heat conduction is generally described by the parabolic heat conduction equation for given initial temperature and boundary conditions, is well-posed problem with smooth dependence of results on initial data. However, many practical problems require solving heat conduction problem when based on final temperature distribution one has to find initial distribution. This problem is proven to be ill-posed and initial imperfections, even very small, will grow large during backwards evolution. There are some regularization techniques (for example, approximation of Lattes&Lions, Tiba, pseudo-parabolic) which approximate our ill-posed problem by well-posed problem. These techniques add regularization terms in original equation.

These terms are scaled by small regularization parameter, ϵ, and the solutions of regularized equations converge to the solution of original with $\epsilon\to 0$. However, if $\epsilon\neq 0$ two approaches, original backwards heat conduction problem (BHCP) and regularized BHCP may differ significantly. Thus, we need to understand when we can expect that regularized equations give acceptable approximation of BHCP. And we want to compare and understand acceptability of each of three methods: 1) quasi-reversibility (Lattes&Lions, 1969), 2) elliptic (Tiba, 1995), 3) pseudo-parabolic (Samarskii). If ϵ grows then the solutions of our regularized equations are stable but error of difference between two solutions (regularized and original) grows. If ϵ is very small regularization procedure is not effective, and some small initial perturbations grow exponentially with time. For each method we plot phase-diagrams which show the optimal choice of regularization terms. We compare these methods on one phase diagram in which domain what method is the best (for what method analytical solution of perturbed BHCP is nearest to analytical solution of BHCP for different frequencies and regularization parameters). For numerical solutions of these regularized problems we plot diagrams for few different frequencies which analyze their convergent, proximity to the analytical solutions that is show which method better for different parameters. After that we introduce another much known method, the iterative method, and in the end a mix of both types of methods to get a good solution of our backwards heat conduction problem.

IC/PP2091/048: An application of scaling inequality in nonlinear PDEs: an example of global stabilization of Burger's equation.

Presenter: Selvaraj Marshal Anthoni (Periyar University, India)

In this paper, we consider the problem of Neumann and Dirichlet control of Burger's equation. The purpose is to derive boundary control laws which make the system globally asymptotically stable. Scaling inequality is used for achieving the required robustness in Lyapunov-based stabilization. Especially this paper focuses on a new freedom of scaling with respect to spatial variables, which is naturally useful to nonlinear PDE's.

IC/PP777/015: A generalized Paneitz–Branson type equation on complete manifolds.

Presenter: Youssef Maliki (University Abou Bekr Belkaïd of Tlemcen, Algeria)

Let (M, g) be an n-dimensional Riemannian manifold with $n \geq 5$. The well known Paneitz–Branson type equation is of the form

$$\Delta_{\tilde{g}}^2 u - \operatorname{div}\Big(\frac{(n-2)^2}{2\,(n-1)\,(n-2)}\operatorname{scal}_g - \frac{4}{n-2}\operatorname{Ricc}_g\Big)\mathrm{d}u + \frac{n-4}{2}Q_g\,u = \frac{n-4}{2}Q_{\tilde{g}}\,u^{\frac{n+4}{n-4}}$$

where Δ_g is the Laplace–Beltrami operator, $Q_g = \frac{1}{2(n-1)}\Delta_g \operatorname{scal}_g + \frac{n^3-4n^2+16n-16}{8(n-1)^2(n-2)^2}\operatorname{scal}_g^2 - \frac{2}{n-2}\,|\operatorname{Ricc}|^2$ and $\tilde{g}$ is a conformal metric to g.

This equation is related with the study of the so-called Q-curvature; that is, a positive smooth solution provides a metric conformal to the background metric g, with the prescribed Q-curvature.

For $1 < p < \frac{1}{2}n$, we consider the following generalization:

$$\Delta_{\tilde{g}}^2\left(\left|\Delta_g\right|^{p-2}\Delta_g u\right) - \operatorname{div}\left(a(x)\,\left|\nabla_g u\right|^{p-2}\nabla_g u\right) + b(x)\,|u|^{p-2}\,u = f(x)\,|u|^{\frac{np}{n-2p}-2}\,u$$

Our aim is to solve this new equation on complete non-compact Riemannian manifolds. We prove that under some conditions on the geometry of the manifold together with conditions on the decay of the function f at infinity, this equation admits a weak solution.

05: Applied Analysis, Minisymposia

IC/MP4401/015: Mathematical aspects of materials science: plasticity and fracture.

Organiser: Antonio DeSimone (SISSA, Trieste, Italy)
Co-organiser: Stefan Müller (Max-Planck-Institut Leipzig, Germany)

See minisymposium IC/MP53/015 on page 393.

Rigidity results for cracked bodies. **Antonin Chambolle** (École Polytechnique, France) IC/MT1451/015

I will present exact rigidity results in the class of SBV functions and SBD displacement, which model respectively deformations and small displacements of cracked bodies, with discontinuities. For the first class, it is reasonable to wonder whether a deformation whose gradient is a.e. a rotation is "piecewise" affine (and piecewise a rigid deformation). For the second class, the natural question is whether $e(u) = 0$ (the absolutely continuous part of the symmetrized distributional gradient) implies also that u is piecewise rigid. In both cases, the answer is false without additional assumptions, thanks to a result of Alberti. We show that if the total surface of the jump set is finite, the answer to both questions is positive. The proof is based on a simplification technique, based on slicing, which turns functions with arbitrary jump set (but of finite measure) into nice functions with piecewise affine jump. In the SBD case, it is sufficient to deduce the rigidity. In the SBV case, it gives only some information on the curl of the approximate gradient. The conclusion then follows from a quantitative rigidity estimate in $W^{1,p}$ of Friesecke, James and Müller, together with an approximation argument borrowed from their proof. This is a work in collaboration with A. Giacomini and M. Ponsiglione.

Quasi-static evolution problems in plasticity with softening. **Gianni Dal Maso** (SISSA, Trieste, Italy) IC/MT3437/015

In plasticity theory the term softening refers to the reduction of the yield stress as plastic deformation proceeds. We deal with this problem in the quasistatic case, in the framework of small strain associative elastoplasticity. The presence of a nonconvex term due to the softening phenomenon requires the extension of a variational framework proposed by Mielke to the case of a nonconvex energy functional. In this problem the use of global minimizers in the corresponding incremental problems is not justified from the mechanical point of view. We analize a different selection criterion for the solutions of the quasistatic evolution problem, based on a viscous approximation. In view of the nonconvexity of the problem, taking the limit as the artificial viscosity parameter tends to zero leads to a weak formulation of the problem in a space of Young measures. Moreover, since the growth exponent of the energy is one, we need a suitable notion of generalized Young measure in order to deal with concentration effects. Finally, the classical notion of total variation of a time-dependent function on a time interval has to be extended to time-dependent families of Young measures. This enables us to define, in this generalized context, a notion of dissipation, which plays a crucial role in Mielke's variational approach. Some examples show that smooth initial data may lead, after a critical time, to a Young measure solution with concentration phenomena.

These results have been obtained in collaboration with Antonio DeSimone, Maria Giovanna Mora and Massimiliano Morini.

Existence of energetic solutions in finite-strain plasticity. **Alexander Mielke** (Weierstraß-Institut Berlin, Germany) IC/MT3585/015

Most theories of finite-strain elastoplasticity are based on Kröner and Lee's assumption of the multiplicative decomposition $\nabla\varphi = F_{\text{elast}}P^{-1}$ of the gradient of the deformation $\varphi : \Omega \to \mathbb{R}^d$. The plastic tensor P and additional hardening variables $p \in \Pi$ are taken to be internal parameters. Moreover, the modeling is usually done in the rate-independent setting. This talk concerns the implications of these two basic axioms. Our analysis uses the *energetic formulation* in its recent abstract form [1,4]. It is solely based on the *energy functional*

$$\mathcal{E}(t,\varphi,P,p) = \int_\Omega W_{\text{elast}}(x,\nabla\varphi P^{-1},p)+W_{\text{hard}}(x,P,p)dx+G_{\text{reg}}(P,p)-\langle \ell(t),\varphi\rangle$$

and the *dissipation distance* $\mathcal{D}((P_0,p_0),(P_1,p_1)) = \int_\Omega D(x,(P_0,p_0),(P_1,p_1))dx$. If $\mathcal{F}$ is the set of kinematically admissible deformation and $\mathcal{Z}$ is the set of all internal states, we call a function $(\varphi,P,p) : [0,T] \to \mathcal{F}\times\mathcal{Z}$ an *energetic solution*, if for all $t \in [0,T]$ the global stability (S) and the energy balance (E) hold:

(S) $\forall\,(\psi,Q,q) \in \mathcal{F}\times\mathcal{Z}$: $\mathcal{E}(t,\varphi(t),P(t),p(t))$
$hspace*{11em} \le \mathcal{E}(t,\psi,Q,q)+\mathcal{D}(P(t),p(t),Q,q)$,

(E) $\mathcal{E}(t,\varphi(t),P(t),p(t)) + \text{Diss}_{\mathcal{D}}((P,p),[0,T])$
$hspace*{7em} = \mathcal{E}(0,\varphi(0),P(0),p(0)) + \int_0^t \partial_s\mathcal{E}(s,\varphi(s),P(s),p(s))ds.$

We address the question under what conditions we can find such energetic solutions, or as a preliminary result we discuss existence of solutions to the associated incremental minimization problems. Our results strongly depend on the regularizing term G_{reg}. The case without regularization is treated in [3], a term involving $\text{curl}P$ is discussed in [5], and regularizations involving $(\nabla P,\nabla p)$ are treated in [2].

Energy-dissipation functionals in fracture mechanics: crack branching and the mother–daughter mechanism. **Christopher Larsen** (Worcester Polytechnic Institute, USA), Michael Ortiz (California Institute of Technology, USA) IC/MT5054/015

Motivated by the idea that energy dissipation due to crack propagation occurs at crack fronts and might depend nonlinearly on propagation speed, we sought reasonable definitions for crack *front* and *front speed* and then analyzed energy-minimization models for crack trajectories. For a crack trajectory $t \mapsto C(t) \subset \Omega$, we say that at each time $t \in [0,T]$ the crack has front $F(t)$ with speed $v(x,t)$ if F and v satisfy the following:

$$\int_0^T \dot\varphi(t)\int_{C(t)} f(x)\mathrm{d}\mathcal{H}^{N-1}(x)\mathrm{d}t = -\int_0^T \varphi(t)\int_{F(t)} f(x)v(x,t)\mathrm{d}\mathcal{H}^{N-2}(x)\mathrm{d}t$$

$\forall\varphi \in C_{01}([0,T]), \forall f \in C_0(\Omega)$, with $F(t)$ being the minimal such set.

For this definition, discrete-time minimization is not very natural, and we turn instead to a model introduced by Mielke and

Ortiz for energy-minimizing trajectories. There are several issues in proving existence, mostly due to compactness problems for crack trajectories satisfying this equation. We will describe these issues (some of which involve mother–daughter cracks), as well as an existence result for a constrained problem and relaxation results for unconstrained problems.

This is joint work with M. Ortiz and C.L. Richardson.

IC/MP617/015: Microstructures, PDE and applications.

Organiser: Robert Lipton (Louisiana State University, USA)
Co-organiser: Alain Damlamian (Université Paris XII, France)

Microstructured materials appear naturally and are increasingly being adopted for use in the applications. The rapidly growing number of applications and contexts for microstructured materials, including those with optimal properties, provides new challenges for modeling and theory. The objective of this minisymposium is to provide a forum for the latest trends and methods used to quantify physical phenomena associated with microstructured media. The mathematical techniques covered in this symposium include homogenization theory, gamma convergence multi-scale numerical methods, regularity theory and methods for local field construction. The application areas include, imaging, composites, biological structures, optimal design, and phase transformations.

Homogenization of the Hall effect in dimension 2 and 3. **Marc Briane** (INSA Rennes, France) IC/MT1303/015

The present work is the fruit of a collaboration with G. Milton, and deals with the homogenization of the Hall effect in two and three dimensions. In Physics it is known that a low (constant) magnetic field induces a non-symmetric perturbation in the resistivity of a conductive material. When the material has a prescribed microstructure, Bergman derived in particular cases the effective (or homogenized) Hall effect from the one of the original microstructure combined with some currents in absence of magnetic field. In this work we extend the Bergman approach to any microstructure in the framework of the Murat-Tartar H-convergence. Moreover, we give some properties of the effective Hall effect. In dimension two we prove in collaboration with D. Manceau that the Hall effect reduces to one coefficient called the Hall coefficient, and that the homogenization process preserves the sign of the Hall coefficient. The three-dimensional case is more delicate. On the one hand, the Hall effect is now represented by a whole 3×3 matrix. On the other hand, the two-dimensional positivity property does not hold in dimension three. Indeed, we build a new microstructure with many symmetries associated with a positive isotropic Hall matrix such that the effective Hall matrix is still isotropic but negative.

Applications of homogenization techniques to the electrical conduction in biological tissues. **Micol Amar** (Università degli Studi di Roma “La Sapienza", Italy), Daniele Andreucci (Università degli Studi di Roma “La Sapienza", Italy), Paolo Bisegna (Università degli Studi di Roma Tor Vergata, Italy), Roberto Gianni (Università degli Studi di Roma “La Sapienza", Italy) IC/MT1711/015

It is well known that electric potentials can be used in diagnostic devices to investigate the properties of biological tissues. Such techniques are essentially based on the possibility of determining the physiological properties of a living body by means of the knowledge of its electrical resistance. This leads to an inverse problem for the Laplace equation, which is the standard equation, when only a resistive behavior of the body is assumed. However, it has been observed that, applying high frequency alternating potentials to the body, a capacitive behavior takes place. This effect (known in physics as Maxwell-Wagner effect) is due to the electric polarization at the interface of the cell membranes, which act as capacitors, and it has been studied, among others, by the authors, who assume that the biological tissue is modeled as a composite media with a periodic microscopic structure composed by two finely mixed phases (intra and extra cellular) separated by an imperfect interface (cellular membrane).

The mathematical description of the passage of the electrical current trough the tissue is given by a system of decoupled elliptic equations in the two phases, whose solutions are coupled because of the interface conditions, since they have to satisfy the property of flux-continuity and a transmission condition of dynamic type. The homogenization theory is used in order to pass from this microscopic description to the macroscopic one, which is given by a new equation, replacing the elliptic one used up to now.

Actually, other different microscopic models have been proposed in the literature, in order to take into account these capacitive effects. These models are obtained by different scalings (with respect to the characteristic dimension of the cell) of the parameters defining the physical behavior of the cell membranes and they lead to different macroscopic equations.

The authors discuss and compare these different models and investigate how microscopic mathematical descriptions can be obtained from the Maxwell equations in the quasi-stationary approximation. This analysis presents a unified derivation of different schemes, thus allowing a comparison among their underlying physical assumptions, and could be useful to assess the viability of each scheme as a model for a specific experimental setting.

Asymptotics for the voltage potential in a periodic network with localized defects. **Eric Bonnetier** (Université Grenoble I, France) IC/MT2188/015

We consider the restriction to an open bounded set Ω of the square lattice $h\mathbf{Z}^2$ as a network of conductors. In the reference configuration, each lattice point is connected to its 4 closest neighbors by a link of conductivity k. In a perturbed configuration, some of the links far from the boundary are defective and have conductivities $k_d \neq k$. Given a current flux on $\partial\Omega$, we compare the potentials u_h and $u_{h,d}$ of the reference and perturbed configurations. We show that at a point z far from the defective zone the potential difference has the form

$$u_{h,d}(z) - u_h(z) \quad = \quad h^2 \sum_i M_i : \nabla u(x_i) \otimes \nabla G(x_i, z) \; + \; o(h^2).$$

In this expression, x_i denotes the location of the i-th defect and h the lattice size. The matrix M_i is a polarization term, ∇u is the potential of the continuous effective medium obtained when $h \to 0$, and G is the Green's function associated to this same limiting effective medium. Thus, the expansion of $u_h - u_{h,d}$ has the same structure as the expansions derived when a smooth medium is perturbed by inclusions of small sizes, and for which efficient numerical detection algorithms have been proposed, taking advantage of the singular character of the Green's function. Our proof for the convergence of the expansion for $u_h - u_{h,d}$ is based on uniform $W^{1,\infty}$ estimates on the potential u_h of the reference network and on the corresponding discrete Green's function. These estimates are derived using the periocity of the reference network and the 3 step compactness method of A. Avellaneda and F.H. Lin (Comm. Pure Appl. Math., 40, pp. 803-847, 1987). Work done in collaboration with Sivaji Ganesh Sista.

A hierarchical structural and material optimization model for bone-remodelling simulation. **Helder Rodrigues** (Universidade Técnica de Lisboa, Portugal), Pedro Coelho (Universidade Nova de Lisboa, Portugal), Paulo Fernandes (IDMEC-IST, Portugal) IC/MT2446/015

Bone is a natural cellular material that is in a permanent process of remodeling. The bone remodeling depends on biological and mechanical factors. This work describes a computational model where the law of bone remodeling is derived assuming that bone adapts in order to achieve the stiffest structure for given load conditions while the total amount of bone mass is regulated by a global constraint quantifying the biological factors . Here bone is assumed to be a non homogeneous cellular periodic material characterized locally by a material unit cell that can vary from point to point. The model assumes two scales for the problem: The global scale (structural or macro scale) where bone is assumed as a continuum material characterized by equivalent (homogenized) mechanical properties. And a local scale (material or micro scale) where the material unit cell and the respective trabecular structure are defined. At the global scale the problem is to find the bone apparent density distribution and its equivalent material properties. On the other hand and simultaneously, at a local scale the objective is to identify the optimal unit cell characterizing the cellular material. Such model allows the simulation of the remodeling process at two different but interrelated levels, bridging the fundamental scales present (hierarchical). Numerical examples show that bone apparent density and material symmetry distributions are comparable to real bone indicating that bone is actually subjected to an adaptation process that can be modeled with an optimization criterion. However, when the goal is to obtain specific properties of trabecular architecture it is concluded that stiffness is a poor criterion and biological constraints should be carefully considered for a better representation of the bone remodeling process.

Numerical boundary corrector for elliptic equations with rapidly-oscillating coefficients and new regularity results. **Marcus Sarkis** (WPI/USA and IMPA/Brazil), Henrique Versieux (Courant Institute of Mathematical Sciences, USA) IC/MT2587/015

We introduce and analyze a numerical discretization for a second-order elliptic equation with rapidly oscillating coefficients. The major goal is in the development of a finite element scheme on a mesh size much larger than the scale of the oscillating coefficients and still capturing the oscillations of the solution. The proposed numerical method is based on homogenization theory, and on hybrid finite element methods to treat the boundary corrector term. On the talk we discuss new results on the regularity of the solution of the PDE and on optimal discretization errors. We stress cases where very mild regularity is assumed on the coefficient and so applications to composite materials can be acomplished. Numerical results are presented.

The unfolding approach for the Neumann sieve and other 'strange terms' in periodic homogenization. **Alain Damlamian** (Université Paris XII, France) IC/MT2627/015

We present an extension of the periodic unfolding method which is suited for boundary layers as well as interior layers or "bulk layers", in a periodic setting. As an example, we show how it applies to obtain the "strange term" for periodic homogenization with small Dirichlet holes, as well as to obtain the limit equations for the Neumann Sieve.

A 0-Laplacian approach to impedance imaging. **Yves Capdeboscq** (Université de Versailles St-Quentin, France) IC/MT2674/015

Impedance imaging uses measurements of boundary voltage potentials and associated boundary currents to obtain informations about the internal conductivity profile of an object. Without any *a priori* assumptions about the conductivity profile, impedance imaging is known to be extremely ill-conditioned. The conditioning may be drastically improved in several practical important cases, one such case is that of a known background medium with low volume fraction inhomogeneities. In such a case, the first order perturbation induced by the inhomogeneities appears by the mean of a polarization tensor.

The subject of this talk is to show that such a tool can also be used for the determination of a global conductivity profile of an arbitrary object, provided that the electric measurements are coupled with elastograhic data.

The underlying non-linear partial differential equation to be solved is of the form

$$\operatorname{div}\left(a(x)\frac{\nabla u}{|\nabla u|^2}\right) = 0,$$

which can be interpreted as a 0- Laplacian. We will show that this equation can be successfully solved to recover the conductivity map.

This work is a collaboration with H. Ammari and E. Bonnetier.

Local-field assessment inside multi-scale composite microstructures. **Timothy Breitzman** (Universal Technology Corporation, USA), Robert Lipton (Louisiana State University, USA), Endel Iarve (University of Dayton Research Institute, USA) IC/MT3352/015

We introduce a new rigorous asymptotic theory for recovering the local field behavior inside multi-scale prestressed composite micro-structures. The theory applies to zones containing abrupt changes in the composite microgeometry. This includes the interfaces between plies inside fiber reinforced laminates. The asymptotic expansions are used to develop a fast numerical algorithm to extract local field information inside a prescribed subdomain without having to resort to a full numerical simulation. For regions of homogeneous microstructure, the analysis delivers rigorous upper bounds on the magnitude of the local stress and strain fields inside the composite. Numerical examples are provided to demonstrate the utility of the new asymptotic theory for quickly assessing the location and magnitude of local field concentrations inside complex multi-scale composite microstructures

IC/MP335/015: Mathematical challenges in the geosciences.

Organiser: Carsten Mayer (TU Kaiserslautern, Germany)

During the last years technological progress has changed the observational methods in all fields of geosciences completely. Modern satellite based techniques are entering geoscientific fields like geophysics, geodesy, meteorology and many others. The increasing flow of data of very high accuracy demands adequate mathematical tools to solve the geoscientific problems. Techniques from fields like constructive approximation, differential and integral equations, potential theory and many more have to be developed in order to assess the data and to build an objective basis for scientific solution of geoscientific problems.

Locally-supported spherical wavelets based on block grids. **Michael Schreiner** (Neu-Technikum Buchs, Switzerland) IC/MT1897/015

We present a method for approximating spherical functions from discrete data on a block grid structure. The essential ingredients of the approach are scaling and wavelet functions within a biorthogonalisation process generated by locally supported zonal kernel functions. In consequence, problems involving rotation–invariant pseudodifferential operators become attackable. A multiresolution analysis is formulated enabling a fast wavelet transform similar to the algorithms known from one–dimensional Euclidean theory.

Slepian functions on the sphere: problems, solutions, challenges. **Frederik Simons** (Princeton University, USA), F Dahlen (Princeton University, USA), Mark Wieczorek (IPG Paris, France) IC/MT1142/015

I will review the properties of spherical Slepian functions and discuss their meritorious applicability in the Earth and space sciences. In a 2006 SIAM Review paper, we named "Slepian functions" those linear combinations of surface spherical harmonics that, while bandlimited, are optimally concentrated in a surface spatial domain of arbitrary description, or, alternatively, those that are strictly spacelimited but optimally concentrated in the spectral domain. They are eigenfunctions of a "spatiospectral concentration kernel", the spherical analogue of an operator first studied by David Slepian, in one and two, and later by Alberto Grunbaum, in higher dimensions. If the region of concentration is an axisymmetric polar cap, or an (also equatorially symmetric) double polar cap, the spherical Slepian matrix concentration operator commutes with a simple tridiagonal matrix that has analytically prescribed elements, and their eigenfunctions, the (spherical harmonic expansion coefficients of) Slepian functions are found easily and with great stability. For applications in the Earth sciences, the spatial concentration domain would be a geologically relevant domain (Belgium or all of the World's oceans), in which case the concentration operator may be found by numerical integration. Slepian functions are not wavelets, but they are self-similar in an asymptotic limit of large bandwidths and small concentration areas. We may use them to calculate local spatial contributions to the global spherical harmonic spectrum of geophysical fields, such as Earth or planetary gravity, topography or their correlation. They are useful to compute global spherical harmonic expansions and spectra of fields observed over incomplete domains, such as Earth or planetary magnetic fields, which typically are unobserved over small polar caps, or, farther out in the solar system, to compute the cosmic microwave background spectrum from observations masked by strong emissions from the galactic plane.

Efficient reconstruction of functions on the sphere from scattered data. **Daniel Potts** (TU Chemnitz, Germany), Jens Keiner (Universität Lübeck, Germany), Stefan Kunis (TU Chemnitz, Germany) IC/MT3434/015

Recently, fast and reliable algorithms for the evaluation of spherical harmonic expansions have been developed. The corresponding sampling problem is the computation of Fourier coefficients of a function from sampled values at scattered nodes. We consider a least squares approximation as well as an interpolation to the given data. Our main result is that the rate of convergence of the two proposed iterative schemes depends only on the mesh norm and the separation distance of the nodes. In conjunction with the nonequispaced FFT on the sphere, the reconstruction of N^2 Fourier coefficients from M reasonably distributed samples is shown to take $\mathcal{O}(N^2 \log^2 N + M)$ floating point operations. Numerical results support our theoretical findings.

From the sphere to more realistic geometries. **Willi Freeden** (TU Kaiserslautern, Germany) IC/MT1831/015

The Earth is an almost perfect sphere. This is the reason why the foundation of my Geomathematics Group Kaiserslautern (in 1994) was meant to improve spherical(ly oriented) tools (such as splines, wavelets etc), e.g., in gravitation, magnetics, hydrodynamics, solid body sciences. The dramatic change in the observational situation caused by modern (satellite) instruments during the last years, however, requires new components of mathematical thinking and adapted strategies to obtain high-precision solutions. In consequence, there is an increasing need for mathematical research observing the non-sphericity of the Earth. The lecture presents recent geomathematical developments on geoscientifically relevant geometries such as ellipsoid, geoid, (actual) Earth's surface, and (real) 'surfaces' of (low) Earth's orbiters.

IC/MP335/015: Mathematical challenges in the geosciences. #2

Organiser: Carsten Mayer (TU Kaiserslautern, Germany)

(For abstract, see session #1 above.)

Wavelets and splines for modelling the earth's magnetic field. **Carsten Mayer** (TU Kaiserslautern, Germany) IC/MT3444/015

At the present time there is an unprecedented opportunity to use satellite magnetometer data, as for example Oersted and CHAMP records, to improve our knowledge of the Earth's magnetic field and its sources. These measurements contain contributions from the main magnetic field of the Earth, the crustal field as well as contributions coming from different exterior (ionospheric and magnetospheric) sources. For the mathematical analysis of the data it is critical to have in hand appropriate tools which separate these sources and which are able to analyze the different contributions independently.

We will present in this talk an approach in terms of (spherical) scalar and vectorial scaling functions and wavelets to handle these problems. Examples include crustal field modelling and reconstruction of ionospheric currents. At the end we will present an approach by vectorial splines defined in the exterior of a sphere, which seam to be more appropriate to handle measurements on realistic satellite orbits.

Modeling of potential fields with wavelet frames. **Matthias Holschneider** (Universität Potsdam, Germany) IC/MT2277/015

We investigate the numerical challenges associated with the modelling of geophysical potential fields with the help of frames. Special emphasis is put to the construction and application of frames of Poisson wavelets.

Using multi-point measurements to investigate waves in the earth's magnetosphere. **Dragoş Constantinescu** (TU Braunschweig, Germany), Karl-Heinz Glassmeier (TU Braunschweig, Germany), Yasuhito Narita (TU Braunschweig, Germany) IC/MT1464/015

Multi-point measurements in the extraterrestrial space have been routinely available only after the launch of the CLUSTER spacecraft fleet at the end of year 2000. Unlike the sensor arrays commonly used in related fields of geosciences, CLUSTER offers only a minimal set of four sensors placed in a tetrahedron configuration. To take advantage of the full potential of these measurements, advanced tools from seismology have been adapted to be used with magnetized plasma waves. One class of these tools uses a minimization technique to decompose the measured wave field into elementary wave components. We present the formalism and application of two of these tools: The *wave telescope* which corresponds to plane waves decomposition, and the *source locator* which corresponds to spherical waves decomposition. For a given frequency they provide either the wave vector or the wave length and the source position, respectively. Using CLUSTER magnetic field measurements it is possible to determine wave propagation directions, dispersion relations, and spatial distribution and motion of the plasma wave sources.

Using non-linear MOS techniques for forecasting global radiation from MSG satellite data. **Martin Fengler** (Meteomedia AG, Switzerland) IC/MT3079/015

For more than 30 years Model Output Statistics (MOS) have been well known to meteorologists. MOS techniques are used for a statistical post-processing of the Direct Model Output (DMO) obtained by numerical weather prediction codes. The success of a MOS system based on classical linear regression originates from ŞlearningŤ a statistical relationship between the weather forecasting model and the local environment of the weather station, e.g. effects in the boundary layer which are not modelled by DMO such as fog, luv- and lee effects, as well as shadow in mountainous terrain. While MOS benefits from a good numerical weather prediction code, it is able to reduce the forecast error for so called point forecasts significantly: For example, depending on the location the mean absolute error in temperature can be decreased from 3-4 K to 0.6-1 K for a day ahead forecast. However, from a mathematical point of view linear regression is for most weather parameters, for example, such as precipitation, wind, radiation, and cloud cover not a suitable approximation method since these predictands are singly or doubly truncated, which is not reflected by the linear model. In this talk we propose non-linear approximation techniques that solve this problem and demonstrate their application to global radiation data obtained from MSG satellite data.

IC/MP183/015: Trends in tomography.

Organiser: Eric Todd Quinto (Tufts University, USA)
Co-organiser: Adel Faridani (Oregon State University, USA)
Co-organiser: Andreas Rieder (Universität Karlsruhe, Germany)

Tomography consists of a broad range of applied mathematics and technologies that are important for medicine and industry, and this minisymposium will feature some of the newest and most exciting developments. Seminal work in several areas will be represented including new methods in three-dimensional tomography including dynamic tomography and sampling, new applications of local tomography to electron microscopy, and thermoacoustic tomography. Combining tomographic reconstruction and post-processing promises to provide better diagnostic information and we will invite speakers to give the latest developments in this area. New algorithms for dynamic CT promise to show heart movement, and researchers will present their latest work. Thermoacoustic tomography is an exciting new field that combines important pure mathematics, the spherical Radon transform, with applications to diagnostic medicine, and in particular cancer detection.

Ultrasound attenuation in thermo-acoustic tomography. **Sarah Patch** (University of Wisconsin, Milwaukee, USA) IC/MT1326/015

Idealized thermo/photo/opto-acoustic (TPOAT) data are unattenuated acoustic pressure measurements, representing spherical integrals of an internal acoustic source. Inversion formulae already exist for idealized data in several different measurement geometries. However, ultrasound pulses attenuate as they travel through biological tissue, degrading reconstructed image quality. Widely accepted accepted models of ultrasound attenuation contradict the widely accepted paradigm of constant and *finite* propagation speed. Different explanations for this paradox will be discussed.

Photo-acoustic tomography with integrating line detectors and the circular Radon transform. **Markus Haltmeier** (Universität Innsbruck, Austria), Robert Nuster (Universität Graz, Austria) IC/MT2757/015

Photoacoustic (or thermoacoustic) tomography is an emerging hybrid imaging method for non-invasive medical diagnosis and fully three-dimensional visualization of biological probes. Within this modality electromagnetic illumination is used to induce acoustic waves inside an object of interest. In this talk we assume that a cylindrical array of line detectors is used to record the acoustical data. This leads to the mathematical problem of inverting the circular Radon transform (or equivalently reconstructing a function from its integrals over certain circles). The circular Radon transform arises in several other up-to-date imaging modalities, such as RADAR imaging or ultrasound tomography.

In this talk we present a stable formula (based on series expansions) for recovering a planar function from its circular Radon transform. We apply this formula to obtain an exact three imaging algorithm for photoacoustic tomography. We present numerical reconstructions with real and synthetic data.

A parametric level-set approach to tomographic reconstruction. **Misha Kilmer** (Tufts University, USA) IC/MT2765/015

A common problem in tomographic imaging is the reconstruction of one or more oddly shaped regions of interest, or hot spots, distinct from the background. In diffuse optical tomography for breast tissue imaging, for example, the goal is to recover 3D images of absorption and diffusion of light in tissue with anomalous regions of high absorption and diffusion indicating the presence of cancer. Unfortunately, many tomographic reconstruction problems are severely underdetermined if each voxel value is independently considered to be an unknown. Furthermore, noise in the measured data makes reconstruction of useful images virtually impossible. We propose a model for the underlying images of interest which makes the problem much better determined, thus improving the computational complexity to the problem, and which helps to address the sensitivity to noise. In particular, we introduce a general formulation of a level-set description of the space-varying perturbation defined through a linear combination of basis functions. Our approach is different from traditional level set approaches in that the inverse problem requires only the reconstruction of the expansion coefficients in the basis, as well as a few auxiliary parameters describing the background and intensity of the anomaly(ies). In this way, we are able to ensure some degree of regularization through the model itself. We present computational results that show the promise of our approach.

This is joint work with Ashley B. Tarokh and Eric Miller

Parameter and structure identification in optical tomography. **Simon Arridge** (University College London, UK) IC/MT2920/015

Optical Tomography is an emerging medical imaging modality that is relatively cheap, fast, and offers a contrast mechanism that is complementary to other modalities such as Magnetic Resonance Imaging. From the mathematical point of view the inverse problem is non-linear and illposed, and is commonly treated as a parameter identification problem for the coefficients of a numerical method such as the finite element method (FEM), typically represented in a local pixel basis. Alternatively, shape based methods, either implicit (such as level sets) or explicit (via a parametric surface model) can be used to identify *structures* . In this talk I will present some recent results comparing these approaches.

Cone beam CT: reconstruction formulas and resolution. **Alfred Louis** (Universität des Saarlandes, Germany) IC/MT2356/015

In cone beam CT the mathematical model is described by the integral transform

$$Df(a,\theta) = \int_0^\infty f(a+t\theta)dt$$

where $a \in \Gamma$ is a source position and $\theta \in S^2$ are the direction of the rays. For curves Γ satisfying the Tuy–Kirillov condition we derive inversion formulas based on the approximate inverse. To this end we study invariances of the operator depending on the curve Γ. If the Tuy–Kirillov condition is not fulfilled we give approximations, and especially for the classical circular scanning geometry we present explicit representations of the reconstruction kernel.

The resolution is studied based on the singular value decomposition for the operator derived from the classical SVD for the Radon and the parallel beam x-ray transform. Applications to x-ray CT and to phase contrast tomography are discussed.

Application of microlocal analysis to electron tomography. **Ozan Öktem** (Sidec Technologies, Sweden), Eric Todd Quinto (Tufts University, USA) IC/MT2018/015

We will begin with a very brief overview of electron tomography from an integral geometric viewpoint with a particular emphasis on the role of the filtered backprojection algorithm. Next, we touch upon a number of difficulties that arise in electron tomography, namely the high degree of clutter, the extremely low signal-to-noise ratio in the data, and the limited data problems that lead to severe ill-posedness. We then present a new local tomographic algorithm applicable to electron tomography and using microlocal analysis, we characterize those singularities that are stably visible from the limited data given by the data collection protocol in the electron microscope. In conjunction with this we also mention some open problems, in particular the problem of defining a concept of resolution. Finally, if time permits, we provide reconstructions from both real and simulated electron tomography data.

Accurate reconstruction of functional and geometric parameters in tomography. **Ronny Ramlau** (RICAM Linz, Austria) IC/MT1837/015

In some medical applications, e.g. for the planning of a surgery, it is necessary to determine the accurate boundary of inner organs. Usually this is done in two steps: First, the density distribution is reconstructed from a CT scan. In a second step the jumps in the reconstruction are determined by image processing methods. In our talk, we propose a variational method that allows to reconstruct both the functional parameters (the density distribution) and the geometric parameters (the discontinuity set). We will restrict ourselfs to the reconstruction of piecewise constant or piecewise smooth functions. The reconstructions will be obtained by the minimization of a Mumford - Shah type functional. We will present analytical results for Computerized Tomography as well as Single Photon Emission Computed Tomography (SPECT). In particular, a regularization theory for our method will be developed. We will give numerical results for both applications and will also consider the limited angle case.

This talk is joint work with Wolfgang Ring (University of Graz, Autria) and Esther Klann (Radon Institute, Linz, Austria).

Current problems in vector and tensor tomography. **Thomas Schuster** (Universität Hamburg, Germany) IC/MT1522/015

Vector and tensor tomography deal with the reconstruction of a tensor field $f = f_{i_1 \dots i_m}$ from observations $\Phi(f)$. Applications can be found in medical imaging, photoelasticity, nondestructive testing, plasma physics or problems connected with electro magnetism. Over the last years not only the areas of applications for that kind of tomography has grown but also the number of approaches for solving the different inverse problems $\Phi(f) \mapsto f$. In this talk we want to give an impression of some tensor tomography problems which are currently under investigation. One important example for a mapping Φ is

given by the cone beam ray transform for tensor fields

$$\mathbf{D}f(\alpha,\omega) = \int_0^\infty \langle f(\alpha+t\omega),\omega^m\rangle\,\mathrm{d}t\,,$$

where $\alpha \in \Gamma$ denotes the source of the beam and $\omega \in S^{n-1}$ is a vector of direction. For $m = 1$ this transform is known as Doppler transform and represents the mathematical model in Doppler tomography. In the talk we present ideas for the inversion of $\mathbf{D}$ with the help of the method of approximate inverse as well as a generalization of the known formula of Grangeat for arbitrary rank m. Some numerical results for the parallel geometry are presented as well. As a relatively new field of tensor tomography concerning tensors of rank 2 we further introduce to the problem of polarization tomolgraphy. Here, the aim is to recover the anisotropic part χ of the permeability tensor $\varepsilon_{ij} = \varepsilon\delta_{ij} + k^{-1}\chi_{ij}$ with the help of Rytow's law:

$$\frac{D\eta}{d\tau} = \frac{i}{2n^2}P_{\dot\gamma}\chi\eta\,.$$

The most general setting of the problem is to determine χ from the linear mapping $U(\gamma)$ satisfying $\eta(1) = U(\gamma)\eta(0)$. We present a uniqueness result for the linearized problem which was obtained by Sharafutdinov. A numerical solver for this highly demanding tomographic problem is still searched.

IC/MP342/015: Bregman distances in optimization, inverse problems and financial mathematics.

Organiser: Elena Resmerita (RICAM Linz, Austria)
Co-organiser: Hansjoerg Albrecher (RICAM Linz, Austria)

Bregman distances associated with convex functions were introduced in the sixties as tools for approaching optimization problems, although particular forms, such as the Kullback-Leibler distance, had been used in information theory and statistics about a decade earlier. Since then, generalized distances have been employed when designing and/or analyzing methods for solving problems from optimization, statistics, inverse problems and, more recently, financial mathematics, machine learning, etc. Nowadays, the interest in using Bregman distances is growing in most of these fields, due to a cross-over effect: new results related to Bregman distances reported in a field have stimulated investigations in others.

The aim of this symposium is an interdisciplinary exchange of research ideas based on the common denominator provided by Bregman distances. The speakers cover some of the many areas which have benefited over the years from the use of Bregman distances. These distances and associated projections have been employed towards the solution of nonlinear operator equations and variational inequalities. In ill-posed inverse problems, such as those encountered in image denoising, Bregman distances have been successfully exploited in various regularization procedures. In mathematical finance, Bregman distances have been used for efficient calibration algorithms of volatility surfaces as well as to determine suitable pricing measures in incomplete markets, for instance in approximation schemes for the arbitrage-free equilibrium pricing measure.

A perspective on Bregman distances, Bregman projections and their applications. **Elena Resmerita** (RICAM Linz, Austria), Dan Butnariu (University of Haifa, Israel) IC/MT515/015

The concepts of Bregman distance and Bregman projection originate in a 1967 work of Lev Bregman. Since then, the use of these concepts became integral part of contemporary convex analysis, leading to a new theoretical paradigm, and to powerful techniques of solving optimization problems, operatorial equations and variational inequalities. The aim of this talk is to presents, in a coherent perspective, basic notions, theoretical results and potential applications which emerged from the study of Bregman distances and Bregman projections. We will touch notions like Legendre function, totally convex function, their inter-relations and connections with the geometry of the spaces in which they are living. We will show how such notions and connections became tools in the build up of algorithms for convex optimization and for other purposes. Also, we will point out some actual and potential applications of those algorithms.

Error estimation in TV imaging. **Martin Burger** (Universität Münster, Germany), Elena Resmerita (RICAM Linz, Austria), Stanley Osher (University of California, Los Angeles, USA) IC/MT628/015

Total variation based methods are popular in image processing due to their cartoon extraction capabilities. Concerning their analysis schemes based on total variation minimization pose various challenging problems caused by the arising degeneracies and strong nonlinearities.
In this talk we will highlight how Bregman distances related to the total variation seminorm can be used to perform error estimation for several total variation based schemes such as the classical ROF model of image processing, iterative refinement, and inverse scale space methods. Moreover, we shall also discuss the use of Bregman distances for the numerical analysis of discretization schemes.

On pricing derivatives under GARCH models: a dynamic Gerber-Shiu's approach. **Hailiang Yang** (University of Hong Kong) IC/MT1284/015

This paper proposes a method for pricing derivatives under the GARCH assumption for underlying assets in the context of a "dynamic" version of Gerber-Shiu's option-pricing model. Instead of adopting the notion of local risk-neutral valuation relationship (LRNVR) introduced by Duan (1995), we employ the concept of conditional Esscher Transforms introduced by Bühlmann et al. (1996) to identify a martingale measure under the incomplete market setting. One advantage of our model is that it provides a unified and convenient approach to deal with different parametric models for the innovation of the GARCH stock-price process. Under the conditional normality assumption for the stock innovation, our pricing result is consistent with that of Duan (1995). In line with the celebrated Gerber-Shiu's option pricing model, we can justify the pricing result within the dynamic framework of utility maximization problems which makes the economic intuition of the pricing result more appealing. In fact, the use of the Esscher Transform for option valuation can also be justified by the minimization of the relative entropy between the statistical probability and the risk-neutralized pricing probability. Numerical results for the comparison of our model with the Black-Scholes option pricing model are presented.

Generalized Kullback-Leibler distances for some optimal financial decisions. **Wolfgang Stummer** (Universität Erlangen-Nürnberg, Germany) IC/MT3864/015

We study Bayesian decision making based on observations of the price dynamics $(X_t : t \in [0,T])$ of a financial asset, when the hypothesis model is a diffusion process with time-dependent volatility and price-dependent drift, and the alternative model is another diffusion process with the same volatility but with different drift.

The presented methods are fundamentally based on investigations about the time-behaviour of power divergences (which are generalizations of the well-known Kullback-Leibler(-Bregman-) distance) between the hypothesis model and the alternative model.

We obtain exact formulae and bounds (in terms of the observation duration T) of the corresponding minimal mean decision loss (Bayes risk, Bayes loss), and the associated decision risk reduction.

We will also show some convergence results for corresponding discrete-time approximations, as well as effects on the non-commutativity between Bayesian statistical and optimal investment decisions.

IC/MP4057/015: Compressed sensing II: algorithms and applications.

Organiser: Justin Romberg (Georgia Institute of Technology, USA)
Co-organiser: Robert Nowak (University of Wisconsin, Madison, USA)
Co-organiser: Jared Tanner (University of Utah, USA)

This minisymposium complements the main Compressed Sensing (CS) one by concentrating on applications of the theory. It includes researchers interested in practical optimization algorithms for recovery from limited measurements, and those developing novel imaging devices based on the methods of CS.

Due to the nascent state of Compressed Sensing, it is particularly important that theoretical researchers interact with those interested in applications. Both the theoreticians and the practitioners will benefit from this interaction. Many practical aspects of algorithms and devices have been influenced by theoretical ideas. Application researchers have begun to see what is and is not practical within the CS framework, and in the process have uncovered interesting mathematical problems.

Compressive imaging. **Justin Romberg** (Georgia Institute of Technology, USA) IC/MT3415/015

We will discuss Compressed Sensing in the context of practical image recovery. Our first topic will be the extension of the CS theory from random measurements to bounds for general measurement/sparsity pairs. Next, we will discus image models that "go beyond ℓ_1", showing how ideas from variational image processing can naturally be incorporated into the CS framework. Finally, we will talk about algorithmic techniques for solving the large-scale optimization problems we encounter in CS.

Task-specific compressive sensing with a multiplexing hyperspectral imager. **Robert Muise** (Lockheed Martin Corporation, USA) IC/MT3476/015

In Task-Specific compressive sensing, the goal is to integrate the sensing process with the final exploitation task in a way that significantly reduces the sensing measurements which would normally be required to reconstruct the entire full resolution scene. We present an algorithm which incorporates a pattern recognition metric into the sensing process. The interaction between the sensing and the exploitation algorithms result in the collection of a variable resolution scene where full resolution is collected only where it is required by the exploitation algorithm. We demonstrate this Task-Specific compressed sensing system utilizes a near Infrared (NIR) Hadamard multiplexing imaging sensor. This prototype sensor incorporates a digital mirror array (DMA) device in order to realize a Hadamard multiplexed imaging system. Specific Hadamard codes can be sent to the sensor to realize inner products of the underlying scene rather than the scene itself. The developed sensing algorithm incorporates the exploitation tasks into the sensing by computing a pattern recognition metric which directs the sensor to collect only the information relevant to the recognition problem. The result is a multiple resolution hyperspectral cube with full resolution where patterns are present and less than full resolution where there are no patterns of interest. We demonstrate this algorithm fully integrated with the sensor and running in real time on a test case to demonstrate feasibility.

Compressive signal processing. **Richard Baraniuk** (Rice University, USA) IC/MT3714/015

Despite the apparent need for adaptive, nonlinear techniques for dimensionality reduction, random linear projections have proven to be extremely effective at capturing signal structure in cases where the signal obeys a low-dimensional model. Similarly, random projections are a useful tool for solving problems where the ultimate question of interest about the data requires a small amount of information compared to the dimensionality of the data itself. The success of random projections in both of these arenas can be traced to an elementary concentration of measure property, which allows us to extend the utility of random projections to a variety of new signal models and applications.

This is joint work with Mark Davenport and Mike Wakin.

The surprising structure of Gaussian point-clouds and its implications for signal processing. **Jared Tanner** (University of Utah, USA), David Donoho (Stanford University, USA) IC/MT3478/015

We will explore connections between the structure of high-dimensional convex polytopes and information acquisition for compressible signals. A classical result in the field of convex polytopes is that if N points are distributed Gaussian iid at random in dimension $n << N$, then only order $(\log N)^n$ of the points are vertices of their convex hull. Recent results show that provided n grows slowly with N, then with high probability all of the points are vertices of its convex hull. More surprisingly, a rich "neighborliness" structure emerges in the faces of the convex hull. One implication of this phenomenon is that an $N-$vector with k non-zeros can be recovered computationally efficiently from only n random projections with $n = 2ek\log(N/n)$. Alternatively, the best $k-$term approximation of a signal in any basis can be recovered from $2ek\log(N/n)$ non-adaptive measurements, which is within a log factor of the optimal rate achievable for adaptive sampling. Additional implications for randomized error correcting codes will be presented.

This work was joint with David L. Donoho.

IC/MP178/015: Compressed sensing.

Organiser: Justin Romberg (Georgia Institute of Technology, USA)
Co-organiser: Robert Nowak (University of Wisconsin, Madison, USA)
Co-organiser: Jared Tanner (University of Utah, USA)

Reconstructing a signal or image from a series of indirect measurements is a fundamental task in the applied sciences. In many applications, the acquisition process can be mathematically modeled as a (known) linear operator applied to an unknown signal or image. There are three central questions:

1. How many measurements are needed in order to produce a faithful reconstruction of the signal/image?
2. How is this reconstruction performed?
3. If there is some control over the measurement process, then what is the best acquisition strategy (linear operator) to use?

The nascent field of Compressed Sensing (CS) addresses these questions using the machinery of computational harmonic analysis. The central results, which have appeared very recently, state that for an appropriate measurement system the number of measurements required to reconstruct an image depends on the *inherent complexity* of the image, rather than the desired resolution of the reconstruction. Numerous algorithms have been recently proposed to perform this reconstruction, drawing on ideas from convex optimization, model selection in statistics, and spectrum estimation in signal processing.

The implications of this newfound theory are widespread. Essentially, it tells us that the number of measurements we need to create high-quality images is far less than the classical Nyquist–Shannon theory suggests. As a consequence, acquisition time can be reduced substantially by committing computational resources to the reconstruction. In addition, the CS suggests new *universal* measurement schemes; non-adaptive linear operators that can be used to reconstruct many different classes of signals.

An information-theoretic view of compressive sampling. **Vivek Goyal** (Massachusetts Institute of Technology, USA), Alyson Fletcher (UC Berkeley, USA), Sundeep Rangan (QUALCOMM Flarion Technologies, USA) IC/MT3526/015

Encouraging recent results in compressed sensing or compressive sampling suggest that a set of inner products with random measurement vectors forms a good representation of a source vector that is known to be sparse in some fixed basis. With quantization of these inner products, the encoding can be considered universal for sparse signals with known sparsity level. We analyze the operational rate-distortion performance of such source coding both with genie-aided knowledge of the sparsity pattern and maximum likelihood estimation of the sparsity pattern. We show that random measurements induce an additive logarithmic rate penalty, i.e., at high rates the performance with rate $R + O(\log R)$ and random measurements is equal to the performance with rate R and deterministic measurements matched to the source.

Compressed sensing and best k-term approximation. **Albert Cohen** (Université Paris VI, France) IC/MT3730/015

In this talk, we shall review several recent results revolving around how well compressed sensing can approximate a given signal from a prescribed budget of linear measurements, as compared to adaptive nonlinear measurements. It will be shown that the answer to this question heavily depends on the norm in which the error is measured, and can be understood through the analysis of the null space of the compressed sensing matrix.

Sampling parametric non-bandlimited signals. **Martin Vetterli** (École Polytechnique Fédérale de Lausanne, Switzerland), Pier Luigi Dragotti (Imperial College London, UK) IC/MT3802/015

Consider the problem of sampling signals which are not bandlimited, but still have a finite number of degrees of freedom per unit of time, such as, for example, piecewise polynomials. Call the number of degrees of freedom per unit of time the rate of innovation. We demonstrate that by using an adequate sampling kernel and a sampling rate greater or equal to the rate of innovation, one can uniquely reconstruct such signals. We thus prove theorems for classes of signals and sampling kernels that generalize the classic "bandlimited and sinc kernel" case. In particular, we show sampling theorems for periodic as well as finite length piecewise polynomials, using a bandlimited derivative kernel, as well as a Gaussian kernel. For infinite signals with a finite local rate of innovation, we show exact local reconstruction algorithms using a rich class of sampling kernels such as functions satisfying Strang-Fix conditions, Exponential Splines and functions with rational Fourier transform. For the case of piecewise sinusoidal signals, we show that there is a trade-off between the number of sinusoids per piece and the proximity of the discontinuities in order to have perfect reconstruction. We thus put forward a parametric uncertainty principle. We also show some extensions to 2-dimensional signals, as well as methods for dealing with the noisy case. All the results presented lead to computational procedures that are readily implementable, which is shown through experimental results. Applications of these new sampling results can be found in signal processing, communications systems and biological systems. In particular, we will show how these results can be used for ultra-wideband (UWB) communications or for image super-resolution.

Sparse representations using constructive frames. **Vahid Tarokh** (Harvard University, USA) IC/MT4433/015

For the noisy sparse representation problem and any arbitrary frame, we will establish a limit on the trade-offs between dimension, sparsity, redundancy and average distortion. We will then present a class of constructive frames endowed with a real time representation algorithm that can approach these limits.

This presentation is based on joint work with Mehmet Akcakaya.

IC/MP178/015: Compressed sensing. #2

Co-organiser: Jared Tanner (University of Utah, USA)

(For abstract, see session #1 above.)

Optimized projections for compressed sensing. **Michael Elad** (Technion – Israel Institute of Technology) IC/MT3431/015

Compressed-Sensing (CS) offers a joint compression- and sensing-processes, based on the existence of a sparse representation of the treated signal and a set of projected measurements. Work on CS thus far typically assumes that the projections are drawn at random. In this talk we describe ways to optimize these projections. Two methods are considered: (i) A direct optimization with respect to the CS performance, targeting CS applied with the Orthogonal Matcing Pursuit (OMP), and (ii) A simpler method that targets an average measure of the mutual-coherence of the effective dictionary. Both techniques are demonstrated and shown to lead to better CS reconstruction performance.

The Johnson–Lindenstraus lemma in compressed sensing. **Ronald DeVore** (University of South Carolina, USA) IC/MT3458/015

We shall show that the Johnson-Lindenstrauss lemma, prominent in the geometry of Banach spaces, implies the Restricted Isometry Property for random matrices. The importance of this result is that there are simple proofs of the JL lemma and thus there is a simple avenue to verify the RIP.

Fast Reconstruction Algorithms for Compressed Sensing. **Robert Nowak** (University of Wisconsin, Madison, USA), Steve Wright (University of Wisconsin, USA) IC/MT3731/015

It is possible to reconstruct a signal from a relatively small number of samples, a number proportional to the number of coefficients required in the optimal compression of the signal. Moreover, these key samples need not be adaptive, instead they take the form of randomized projections of the signal. This new form of sampling, known as Compressed Sensing (CS), is causing a dramatic re-thinking of the basic fundamentals of sensing and sampling. This talk will describe new algorithms for CS reconstruction problems.

Beyond Nyquist: efficient sampling of sparse, band-limited signals. **Joel Tropp** (The University of Michigan, USA) IC/MT3495/015

The standard approach to measuring a bandlimited signal requires samples at the Nyquist rate, which is twice the highest frequency present in the signal. For many signals of interest, this sampling rate is beyond the power of current technologies. Fortunately, most signals contain very few significant frequencies relative to their nominal bandwidth. Recent developments in computational harmonic analysis offer the possibility of acquiring these signals using far fewer samples. One architecture that has been proposed involves modulation of the signal by a random square wave, followed by low-pass filtering and low-rate sampling. This talk describes methods for analyzing this system mathematically. The results establish that the random modulator collects enough information to reconstruct frequency-sparse signals. There are also surprising implications for the implementation of the system.

IC/MP73/054: Wavelet methods for real-world problems.

Organiser: Abul Hasan Siddiqi (King Fahd University, Saudi Arabia)

Wavelet and Gabor analysis have attracted the attention of researchers in different parts of the world belonging to different areas of human knowledge in the recent past. Wavelet packets and Wave packets are comparatively new genralizations of wavelet and Gabor systems. The basic properties of these two systems are being investigated. In the present symposium besides applications of wavelet methods to climatology and finance, fundamental properties of these two new systems will be discussed.

Oil exploration and wavelet microscope. **Abul Hasan Siddiqi** (King Fahd University, Saudi Arabia) IC/MT4978/054

Wavelet analysis is a refinement of Fourier analysis. Its applications to various disciplines such as signal analysis and image processing, meteorology, bioinformatics, pattern recognition, cardiology, scientific computing, financial engineering and stratigraphy have been studied in the recent years. There is a close connection with the Milankovitch theory of climatic change and sedimentary cycles of certain regions of the world.

Definition and interpretation of sedimentary facies often involves examination of well logs to assess values, trends, cycles, and abrupt changes. The procedure, which is often visual inspection of the logs (well logging is a technique used in oil and gas industry for recording rock and fluid properties to find hydrocarbon zones in the geological formations within Earth's crust), could be improved by using recently developed signal analysis and features extraction techniques based on wavelet analysis. In particular, wavelet analysis of logs provides an early interpretable visual representation of signals and is an efficient tool for supporting stratigraphic analysis (stratigraphy is a branch of geology dealing essentially with the study of rock layers and layering. It is mainly used in the study of sedimentary and layered volcanic rocks). Wavelet methodology permits the detection of cyclicities, trends and sudden changes in sedimentary successions. The speaker and his coworkers have tested wavelet methodology for the well logs of an oil field in the Middle East.

Detection of sedimentary cyclicity and stratigraphic completeness by wavelet analysis. **Pammy Manchanda** (Guru Nanak Dev University, India) IC/MT2662/054

On the basis of the time-frequency scaling property of the wavelet transform, accumulation rates and stratigraphic completeness can be calculated for various observation time span by using wavelet analysis. Wavelet analysis also allows automatic detection of high-frequency sedimentary cyclicity and abrupt and gradual variations in sedimentation rate. The preservation of different frequency cycles is strongly dependent on variations of the intensity to noise ratio of the original cycles and accumulation rate through time, as demonstrated by computer models. Application of wavelet analysis will be discussed to detect and correlate periodic-cyclic successions of sediments of oil fields.

Saudi meteorological data analysis through wavelet microscope. **Shafiqu Rehman** (King Fahd University, Saudi Arabia) IC/MT1382/054

Wavelet analysis is a refinement of celebrated Fourier analysis which has played a very vital role in understanding real world problems for more than 200 years. The deficiencies of Fourier methods were realized in forties by some leading scientists of that period. Wavelet analysis has been systematically developed in the last two decades and its applications to diverse fields of human knowledge are being investigated. A plot of wavelet coefficients clearly shows the exact location in time of the discontinuity. Wavelet analysis is capable of revealing aspect of data that other signal analysis techniques, miss, aspects like trends, break down points, discontinuities in higher derivatives and self similarities. Further, because it affords a different view of data than those presented by traditional techniques, wavelet analysis can compress or denoise a signal without appreciable degradation of the original signal. Local features of a signal can be described better with wavelets which have a local extent. The wavelet tools can detect the overall trend of a signal.

The time series of meteorological parameters has so much noise that their overall shape is not visible upon visual inspection. It has been observed in our investigation that trends become more and more readable at decomposition at different scales. The wavelets tools have been used in revealing the trends of the meteorological data time series. If the signal

itself includes sharp changes then successive approximation look less and less similar to the original signal. The present paper deals with the meteorological data visualization such pressure, temperature, relative humidity, rain fall and the wind speed time series of the Kingdom of Saudi Arabia. The analysis in this paper is based on discrete and continuous wavelet transforms. The methodology used in this paper is also applicable to study the problems related to oil exploration.

Analysis of NAO, solar flares and sea level changes. **Z. Can** (Istanbul Aydın University, Turkey), Zafer Aslan (Istanbul Aydın University, Turkey), O. Oguz (Istanbul Aydın University, Turkey) IC/MT3317/054

The Relationship between ENSO with ONI and SL Changes are analyzed to define the role of ELNINO3.4 on sea level variations around Turkey and Indian coasts by using monthly sea level time series at 25 sites. There are positive correlation between SL and ENSO and ONI (Warm and cold episodes based on a threshold of +/- 0.5oC for the Oceanic Niño Index (ONI) based on the 1971-2000 base period. For historical purposes cold and warm episodes are defined when the threshold is met for a minimum of 5 consecutive over-lapping seasons. Different techniques have been used to define El Niño event. The most common ones are the Southern Oscillation Index (SOI) and the Niño regions. The Niño regions refer the SST anomalies in defined parts of the Tropical Pacific. There is sufficient evidence on the relation between time series analysis of Sea Level values and ELNINO indices. In northern coastal part of Turkey, the role of positive effect is high. At the western coastal part of Turkey the relation between ELNINO indices and SL is negative. This relation can also be interpreted by applying 1-D Wavelet and Continuous wavelet packets on data. Cross correlation Maps at regional scale for Turkey and India have been presented.

IC/MP73/054: Wavelet methods for real-world problems. #2

Organiser: Abul Hasan Siddiqi (King Fahd University, Saudi Arabia)

(For abstract, see session #1 above.)

Wavelet analysis in the oil industry. **Aiman Mukheimer** (Prince Sultan University, Saudi Arabia) IC/MT3313/054

In the recent years wavelet and wavelet based multifractal analysis have been applied to study and understand cimatic dynmics of different regions.Recently Siddiqi,Rehman and Abbadi have applied these methods to meteorological data of Saudi Arabia.They have mentioned fairly large number of research papers devoted to applications of wavelet analysis to real world systems.There is a close connection between the Milankovitch theory of climatic change and sedimentary cycles of certain regions.Oil industry is quite dependent on proper understanding of sedimentary facies involving examination and iterpretation of well logs.We discuss here how wavelet analysis is used to asses values,trends,correlation and abrupt changes of parameters such as gamma ray,porosity,density.

Wavelets and deblurring operator in seismic records. **Mohammad El-Gebeily** (King Fahd University, Saudi Arabia) IC/MT2861/054

A fixed point method based on wavelets and the minimization of variation is presented for the identification of the blur operator in seismic records. We assume the knowledge of a blurred record and its original version. From this information the blur operator is identified through wavelet transforms and an iterative fixed point method. Numerical examples will be given to confirm the theoretical findings.

IC/MP568/015: Approximation and analysis on the sphere.

Organiser: Ian Sloan (University of New South Wales, Australia)
Co-organiser: Douglas Hardin (Vanderbilt University, USA)

The 2-dimensional sphere is an important setting for applications in geophysics, quantum physics, particle scattering and other fields, yet it presents many mathematical challenges. Many difficulties arise from the absence (except in the special cases associated with the platonic solids) of regular partitions or regular distributions of points on the sphere. Yet progress is being made. This 2-session minsymposium will present current research on approximation (for example, by polynomials and radial basis fuctions) and related methods for partial differential equations on the sphere, together with properties of minimum energy point distributions, and other problems of discretization.

Sobolev bounds on functions on the sphere, with applications to SBFs. **Holger Wendland** (University of Sussex, UK), Joe Ward (Texas A&M University, USA), Francis Narcowich (Texas A&M University, USA) IC/MT3622/055

In this talk we discuss Sobolev bounds on functions that vanish at scattered points on the n-sphere S^n in $\mathbb{R}^{n+1}$. The Sobolev spaces involved may have fractional as well as integer order. We then apply these results to obtain estimates for continuous and discrete least-squares surface fits via spherical basis functions (SBFs). We also address a stabilization or regularization technique known as *spline smoothing*.

Solving pseudo-differential equations on the sphere. **Kerstin Hesse** (University of New South Wales, Australia), Quoc Thong Le Gia (University of New South Wales, Australia), Ian Sloan (University of New South Wales, Australia) IC/MT1283/054

Many important partial differential equations on the sphere can be considered as pseudo-differential equations. In this talk we consider a class of pseudo-differential equations on the sphere and derive an approximate solution with the help of radial basis function collocation. We present error estimates for the approximate solution to the pseudo-differential equation in a Sobolev space setting. We may also discuss some results on boundary value problems on the sphere. This talk is about joint work in progress with Quoc Thong Le Gia and Ian H. Sloan.

Localized polynomial operators for learning functions on the sphere. **Hrushikesh Mhaskar** (CSU Los Angeles, USA), Quoc Thong Le Gia (University of New South Wales, Australia) IC/MT2557/054

Let $\mathbb{S}^q$ denote the unit sphere in $\mathbb{R}^{q+1}$, and μ be its surface area measure. Given a finite set C of points on the sphere $\mathbb{S}^q$, we discuss algorithms to construct weights w_ξ, $\xi \in C$, such that $\int P d\mu = \sum_\xi w_\xi P(\xi)$ for all spherical polynomials P of degree as high as possible. We illustrate our constructions together with the localization properties of certain polynomial operators with a number of examples.

Spectral approximation of Navier–Stokes equations on the unit sphere. **Quoc Thong Le Gia** (University of New South Wales, Australia), Ian Sloan (University of New South Wales, Australia), Mahadevan Ganesh (Colorado School of Mines, USA) IC/MT1280/054

The Navier–Stokes equations describing the movement of a certain fluid with viscosity ν on the unit sphere are

$$u_t + \nabla_u u - \nu \Delta^* u + \nabla p = f\,, \quad \operatorname{div} u = 0\,, \quad u(0) = u_0\,,$$

in which u is the velocity vector field, Δ^* is the Laplace–Beltrami operator, ∇_u is the covariant derivative with respect to vector u, p is pressure, f is the external force, and u_0 is the initial velocity. In this talk, we discuss the spectral method for approximating the solution of the Navier–Stokes equations on the unit sphere using divergence-free vector spherical harmonics. We estimate the error between the approximate solution and the exact solution when f belongs to a certain Sobolev space or is in the Gevrey regularity class of functions. Numerical simulation of the equation using MATLAB will also be discussed.

IC/MP568/015: Approximation and analysis on the sphere. #2

Organiser: Ian Sloan (University of New South Wales, Australia)
Co-organiser: Douglas Hardin (Vanderbilt University, USA)

(For abstract, see session #1 above.)

Bernstein theorems for SBFs on the n-sphere. **Joe Ward** (Texas A&M University, USA) IC/MT3408/054

Bernstein theorems have been known for years for certain classes of functions such as polynomials or univariate splines. They have proven to be extremely useful in obtaining inverse error estimates. In this talk we will discuss Bernstein theorems for various classes of SBFs on the n-sphere and their role in obtaining inverse error estimates for SBF interpolation in various $L^p(S^n)$ norms.

Divergence-free RBFs on spheres and other surfaces. **Francis Narcowich** (Texas A&M University, USA) IC/MT3570/054

In this talk, we present a new tool, based on radial basis functions (RBFs), for fitting a divergence-free vector field tangent to a two dimensional orientable surface $\mathcal{P} \in \mathbb{R}^3$ to samples of such a field taken at scattered sites on $\mathcal{P}$. In the case where $\mathcal{P}$ is a sphere, there are important physical applications. This is joint work with J. Ward and G. Wright.

Asymptotic results for the weighted best-packing problem on rectifiable sets. **Sergiy Borodachov** (Georgia Institute of Technology, USA), Douglas Hardin (Vanderbilt University, USA), Edward Saff (Vanderbilt University, USA) IC/MT2841/054

Different applications such as computer-aided geometric design require placing a large number of points on a surface according to a given non-uniform distribution. For this reason we consider the following generalization of the best-packing problem. Given a compact set $A \subset \mathbf{R}^{d'}$ and function $w : A \times A \to [0, \infty]$, it is required to find the quantity

$$\delta_N^w(A) := \sup_{x_1,\dots,x_N \in A} \min_{i \neq j} w(x_i, x_j) \left| x_i - x_j \right|. \qquad (1)$$

This problem is the limiting case of the minimum weighted discrete Riesz energy problem. When $w(x, y) \equiv 1$ in (1), we get the best-packing problem.

It is known that for any smooth d-dimensional manifold $A \subset \mathbf{R}^{d'}$ $(d \le d')$

$$\lim_{N\to\infty} \delta_N^1(A) N^{1/d} = C_d \, |A|^{1/d}\,, \qquad (2)$$

where $|\cdot|$ denotes the d-dimensional surface area and C_d is a positive constant independent of A. The limit distribution of optimal configurations as N gets large is uniform. (Constant C_d is related to the largest packing density in $\mathbf{R}^d$ and is known only for $d = 1, 2, 3$ – L.Fejes-Tóth, 1953, T.C. Hales, 2005).

We extend estimate (2) and the distribution result for $A \subset \mathbf{R}^{d'}$ being a d-rectifiable set, i.e. an image of a compact set from $\mathbf{R}^d$ with respect to a Lipschitz mapping. In this case the surface area is replaced by the appropriate normalization of the d-dimensional Hausdorff measure $\mathcal{H}_d$.

We also get an analogue of these results for the quantity (1) with the following assumptions about the weight:

1) w is continuous at a diagonal point (x, x) for $\mathcal{H}_d$-almost all $x \in A$;

2) There are at most finitely many points $a_1, \dots, a_n \in A$ $(n \ge 0)$ such that w has a pole at (a_i, a_i), $i = 1, \dots, n$ (the order of each pole is less than one);

3) For every compact set $B \subset A \times A$ which contains no diagonal points, there holds $\inf_B w(x, y) > 0$;

4) There is a neighborhood G of the diagonal relative to $A \times A$ such that w is bounded from above on any set $G \setminus (U_{a_1} \cup \dots \cup U_{a_n})$, where U_{a_i} is a neighborhood of the point (a_i, a_i), $i = 1, \dots, n$.

Theorem. *Let $A \subset \mathbf{R}^{d'}$ be a d-rectifiable set and w satisfy conditions 1)–4). Then,*

$$\lim_{N\to\infty} \delta_N^w(A) N^{1/d} = C_d \left(\int_A w(x,x)^d \, d\mathcal{H}_d(x) \right)^{1/d},$$

where constant C_d is the same as in (2).

If $\mathcal{H}_d(A) > 0$, then the density of the limit distribution of optimal configurations is proportional to the function $\rho(x) = w(x, x)^d$, $x \in A$.

Locally-supported wavelets obeying boundary conditions. **Willi Freeden** (TU Kaiserslautern, Germany) IC/MT3718/054

This talk deals with the problem of constructing locally supported wavelets on (regular) regions of the (unit) sphere, thereby obeying certain boundary conditions. As an important application in geosciences, the determination of the Earth's sea surface topography from discrete data of the (geostrophic) oceanic flow is discussed on a local (oceanic) area including boundary effects on, e.g., coastlines.

IC/MP53/015: Mathematical aspects of materials science.

Organiser: Antonio DeSimone (SISSA, Trieste, Italy)
Co-organiser: Stefan Müller (Max-Planck-Institut Leipzig, Germany)

In recent years, materials science has provided fertile grounds for the development of new tools in the calculus of variations, partial differential equations, and applied analysis. These new developments have, in turn, contributed to the advancement of our current understanding of complex material behavior.

Examples range from homogenization theory for the computation of effective macroscopic properties, to y-convergence for the derivation of reduced models, to weak convergence methods for bridging over length and time scales.

The minsymposium will review some of the recent key achievements in this area, examine the current trends, and explore some new promising directions.

Orientable and non-orientable director fields for liquid crystals. **John Ball** (University of Oxford, UK) IC/MT4143/015

Uniaxial nematic liquid crystals are often modelled using the Oseen–Frank theory, in which the mean orientation of the rod-like molecules is modelled through a unit vector field n. This theory has the apparent drawback that it does not respect the head-to-tail symmetry in which n should be equivalent to $-n$; that is, instead of n taking values in the unit sphere S^2, it should take values in the sphere with opposite points identified, i.e. in the real projective plane $\mathbf{R}P^2$. The de Gennes theory respects this symmetry by working with the tensor $Q = s(n \otimes n - \frac{1}{3}\mathbf{1})$. In the case of a non-zero constant scalar order parameter s the de Gennes theory is equivalent to that of Oseen-Frank when the director field is orientable.

We report on a general study of when director fields can be oriented, described in terms of the topology of the domain filled by the liquid crystal, the boundary data, and the Sobolev space to which Q belongs (which in turn prevents or allows certain defects).

This is joint work with Arghir Zarnescu.

Fluid flow within a fluid membrane. **Marino Arroyo** (Universitat Politècnica de Catalunya, Spain), Antonio DeSimone (SISSA, Trieste, Italy) IC/MT3706/015

We study the mechanics of fluid membranes with a particular emphasis on the inner flowŰthe motion of the lipids within the membrane surface. For this purpose, we obtain the equations of motion of a two-dimensional viscous fluid flowing on a curved surface that evolves in time. These equations are derived from the balance laws of continuum mechanics, and a geometric form of these equations is obtained. The partial differential equations that govern the time evolution of a fluid membrane driven by curvature elasticity or line tension are obtained. We apply these equations to the formation of a protruding bud in a fluid membrane, as a model problem for physiological processes on the cell wall. The 2D flow is induced by the change in shape of the surface domain in which the flow takes place. We study the kinetics of the budding process driven by line tension or interfacial energy, assuming that the neck of the bud corresponds to an interface between phases. The rate of the process is set by a balance between viscous dissipation within the fluid membrane and interfacial energy release rate.

Surfactants in foam stability: a phase-field model. **Irene Fonseca** (Carnegie Mellon University, USA) IC/MT1225/015

The role of surfactants in stabilizing the formation of bubbles in foams is studied using a phase-field model The analysis is centered on a van der Walls-Cahn-Hilliard-type energy with an added term accounting for the interplay between the presence of a surfactant density and the creation of interfaces. In particular, it is concluded that the surfactant segregates to the interfaces, and that the prescription of the distribution of surfactant will dictate the locus of interfaces, what is in agreement with experimentation.

Screening induced fluctuations and collisions in Ostwald ripening. **Barbara Niethammer** (Humboldt-Universität zu Berlin, Germany) IC/MT1209/015

The long-time behavior of classical mean field models for domain coarsening displays a sensitive dependence on the initial data. Higher order effects, such as screening induced fluctuations in the particle number densities or collision of domains, are possible mechanism to drive the coarsening system toward a unique self-similar state. In this talk I give an overview of the derivation of corresponding models and the analysis of their long-time behavior. (This is joint work with Juan Velazquez)

IC/MP53/015: Mathematical aspects of materials science. #2

(For abstract, see session #1 above.)

Texture and microstructure: a new paradigm. **David Kinderlehrer** (Carnegie Mellon University, USA), Eva Eggeling (Carnegie Mellon University, USA), Maria Emelianenko (Carnegie Mellon University, USA), Shlomo Ta'asan (Carnegie Mellon University, USA) IC/MT1503/015

Nearly all technologically useful materials are polycrystalline, consisting of small crystallites, called grains, separated by interfaces, the grain boundaries. The energetics and arrangement of this network, its texture, are important factors in material behavior, and constitute the basic problem of microstructure. Experimentall, the inverse relationships between grain boundary populations and energy have been observed for many years. We introduce the grain boundary character distribution (GBCD), a new statistic, and offer compelling evidence for its strong dependence on grain boundary energy. In addition we demonstrate that there are natural laws for texture and the GBCD using large network simulations

Energy scaling and domain branching in shape-memory alloys and type-I superconductors. **Sergio Conti** (Universität Duisburg-Essen, Germany) IC/MT3432/015

Many problems in material sciences are characterized by the spontaneous formation of fine-scale structures, whose topology changes depending on the control parameters. The different patterns can be understood using nonconvex functionals with a singular perturbation, which physically represents surface energy terms. Focusing on two specific examples (shape-memory alloys and fl<ux penetration in type-I superconductors), I shall show how a combination of interpolation inequalities and explicit constructions permits to determine the scaling of the minimal energy with respect to the relevant material parameters, and therefore to predict a phase diagram for the observed microstructure. This talk is partially based on joint work with R. Choksi, B. Kohn, F. Otto, and S. Serfaty.

A damped wave-type limit for Landau–Lifshitz–Gilbert equation. **Antonio Capella Kort** (Universität Bonn, Germany), Felix Otto (Universität Bonn, Germany), Christof Melcher (Humboldt-Universität zu Berlin, Germany) IC/MT2661/015

We discuss the Landau–Lifshitz–Gilbert dynamics of magnetic domain walls driven by small applied fields. In certain regimes and geometric configurations, where one of the magnetization's components is heavily penalized, the interplay between energetic and dynamic forces becomes singular. If the Gilbert damping is sufficiently small, an effective damped wave type dynamics of the nonheavily penalized magnetization's components is observed.

In particular we study the effective dynamics of Néel walls in magnetic thin films. We prove in this case, existence of traveling wave and periodic solutions for small, constant and periodic forcing. We also deduce an asymptotic dynamic law for the wall's center q, of the form

$$M\,\ddot{q} + \frac{1}{\beta}\,\dot{q} = H(t)$$

where, M and β are the effective wall mass and mobility, and H is the applied field. This result suggest that, in this regime the domain wall can be considered as a puere topological object, that behaves as a particle of finite mass. We also give explicit expressions for the wall mass and mobility in terms of the static Néel wall profile and various physical constants.

Oscillatory aspects of Landau–Lifshitz–Gilbert dynamics. **Christof Melcher** (Humboldt-Universität zu Berlin, Germany) IC/MT1386/015

Landau-Lifshitz-Gilbert dynamics is the fundamental evolution law in ferromagnetims. It describes a damped precession of the magnetization vector about the effective field steming from the underlying interaction energy. In the simplest cases the equation can be considered as a hybrid heat and Schrödinger flow for harmonic maps into the sphere. In this talk we discuss analytical features of this equation that lead to typical dynamic phenomena such as oscillatory motion of micromagnetic singulaities or the existence of non-coherent precessional states in the presence of a spin torque.

IC/MP624/005: Approximation and point distribution on the sphere.

Organiser: Ian Sloan (University of New South Wales, Australia)
Co-organiser: Douglas Hardin (Vanderbilt University, USA)

The 2-dimensional sphere is an important setting for applications in geophysics, quantum physics, particle scattering and other fields, yet it presents many mathematical challenges. Many difficulties arise from the absence (except in the special cases associated with the platonic solids) of regular partitions or regular distributions of points on the sphere. Yet progress is being made. This minsymposium will present current research on approximation by polynomials and radial basis fuctions and related methods for partial differential equations on the sphere, together with properties of minimum energy point distributions, and other problems of discretization.

Asymptotics for discrete weighted minimum energy problems on the sphere. **Douglas Hardin** (Vanderbilt University, USA) IC/MT3525/055

Given a closed d-rectifiable set A embedded in Euclidean space (for example, $A = S^d$), we investigate minimal weighted Riesz energy points on A; that is, N points constrained to A and interacting via the weighted power law potential $V = w(x,y)\,|x-y|^{-s}$, where $s>0$ is a fixed parameter and w is an admissible weight. (In the unweighted case ($w \equiv 1$) such points for N fixed tend to the solution of the best-packing problem on A as the parameter $s \to \infty$.) Our main results concern the asymptotic behavior as $N \to \infty$ of the minimal energies as well as the corresponding equilibrium configurations. Given a distribution $\rho(x)$ with respect to d-dimensional Hausdorff measure on A, our results provide a method for generating N-point configurations on A that are "well-separated" and have asymptotic distribution $\rho(x)$ as $N \to \infty$? This is joint work with E. B. Saff and S. V. Borodachov.

Constructive approximations of spherical functions . **Mahadevan Ganesh** (Colorado School of Mines, USA) IC/MT1375/005

Approximation of functions on the sphere arises in almost all applications modeling data collected on the surface of the earth and for reconstruction of various processes in spherical coordinates. Interpolation operators on the circle and periodic domains (based on a class of basis functions and data values) are essential for many high performance simulations. These operators are represented by analytical summation formulas that can be computed very efficiently using the fast Fourier transform. We construct a similar class of interpolation and quasi-interpolation operators on the sphere using a new class of basis functions and demonstrate the power of such operators with several benchmark numerical experiments. This is a joint work with H.N. Mhaskar.

Extremal spherical designs. **Robert Womersley** (University of New South Wales, Australia) IC/MT3128/055

A spherical n-design is a set of m points on the unit-sphere S^2 such that the corresponding equal weight cubature rule is exact for all spherical polynomials of degree at most n. Traditionally the interest has been in finding the points that give the largest value of n for a given m, or equivalently in looking for the smallest number of points m for a given n. Theoretically the best known results valid for all $n \geq 0$ have $m = O(n^3)$, in contrast to the known lower bounds $m \geq n^2/4 + O(n)$, which are not achievable except in a few special cases.

However there is very strong numerical evidence that $m = (n+1)^2$, the dimension of the space of all spherical polynomials of degree at most n, is more that adequate. Moreover this number of points leaves some freedom, which can be used to choose points with another desirable characteristic. One such characteristic is to maximize the determinant of the basis matrix, as is done for D-optimal designs in statistics. The extremal points of Womersley and Sloan, with their (numerically) positive cubature weights, provide excellent starting points for finding extremal spherical designs. Spherical designs are also an example of quasi-Monte Carlo (QMC) points for the sphere.

This talk looks at characterisation of extremal spherical designs with $m = (n+1)^2$ points as constrained global optimization problems. Lobatto like versions, with the additional condition of points at the north and south poles, are also considered. Some of the nice properties of these point sets, which make them suitable for both numerical integration and polynomial interpolation over the sphere, are presented.

Constructive approximation on the sphere. **Ian Sloan** (University of New South Wales, Australia) IC/MT1372/005

As building blocks for approximation on the sphere both radial basis functions (RBF's) and polynomials have their advantages: RBF's are good for scattered data, can be concentrated in regions where the variation is rapid, and can have compact support; while polynomials are good for slowly varying global phenomena. Here, in joint work with Alvise Sommariva, we discuss a constructive hybrid approximation, one that seeks to combine the virtues of both RBF's and polynomials.

Finite reflection groups and spherical Radon transform. **Paula Cerejeiras** (Universidade de Aveiro, Portugal) IC/CT3576/015

Texture analysis deals with the experimental determination and interpretation of the statistical distribution of orientations of crystals within a specimen of poly-crystalline materials (the orientation of each individual crystal assumed to be unique). The localization can be preformed via the inversion of a spherical Radon transform - a ill-posed problem.

In this talk we study the problem of localization and inversion of the spherical Radon transform under the action of conformal transformations φ_a linked to the special symmetries of the crystal as described by the finite reflection group.

Study of the convergence of a non-iterative splitting scheme. **Elodie Tillier** (Institut Français du Pétrole, France) IC/CT2319/051

The modelisation of the CO_2 geological storage gives a reactive multiphase flow problem. We use to solve it a non iterative splitting method which consist in decoupling the multiphase flow model and the reactive transport model. The error introduced by the splitting is corrected by a penalization term. The objective of this paper is to study the validity of this method. We simplify the full problem in order to be able to make a theoretical study. To do that, we consider just one species which can be present in aqueous and in gaseous phase, and a mineral. We are interested by the equilibrium between the species in gaseous phase and in aqueous phase, and by the kinetic reaction with the mineral. It gives a simplified two phase diffusion-reaction problem. We first write the continuous problem for the splitting method. Then we propose a finite volume scheme. We show that this scheme converges to the weak solution of the initial continuous problem. First, we show that the approximate solution obtain with the splitting scheme converges to the weak solution of the splitting continuous problem, then, by passing to the limit, we show that it also converges to the weak solution of the initial continuous problem. Work done in collaboration with Robert Eymard and Laurent Trenty.

Scattering of flexural gravity waves by abrupt change in water depth. **Trilochan Sahoo** (IIT, Kharagpur, India), Debabrata Karmakar (IIT, Kharagpur, India) IC/CT31/101

In the recent decades, there is a large interest in analyzing wave interaction with large floating flexible structures which has wide application in both ocean engineering and cold region science and technology. In the construction of very large floating structures such as floating airports, the structures are considered flexible in nature. The floating ice sheets that cover a vast area of the ocean surface in the cold regions are also modeled as flexible structures and are used for various human activities. The surface gravity waves originated in the open sea interact with the floating flexible structures and penetrates into the region covered by the flexible structures to generate flexural gravity waves. Chen et al. (2006) reviewed the hydroelasticity theories for global response of marine structures. On the other hand, the various aspects of wave ice interaction problems are investigated by various researchers (see Porter and Porter (2004), Manam et al. (2006) and the literature cited there in) in the recent literature.

In the present paper, the scattering of flexural gravity waves due to an abrupt change in ocean depth is analyzed in case of finite depth in the linearized theory of water waves. In the present paper, Timoshenko–Mindlin equation for the plate equation is used to include shear and inertia effect in the plate equation. The generalized expansion formulae along with the corresponding orthogonal mode-coupling relations are used to obtain the velocity potential for the boundary value problem associated with the physical problem which is also derived based on the direct application of GreenŠs integral theorem. Using GreenŠs identity the relation between reflection and transmission coefficients is obtained which is used for checking the accuracy of the numerical computations.

Existence of best approximant in a nonconvex domain. **Hemant Kumar Nashine** (Chhattisgarh Swami Vivekanand Univeristy, India) IC/CT2691/015

Theory of approximation is one of the important fields of applied mathematics. The concept of best approximation given by Chebyshev is one of the useful technique among several approximation methods. In 1854, Chebeshev developed the notion of a best approximation of continuous functions by polynomials and established a criterion for polynomial for best approximation in the metric space. Leter its application to the various fields of mathematics, has attracted the analysts and now independent theory of best approximation is taking shape convering various approachs.

The aim of the present note is to establish an existence result on best approximation for the nonexpansive mappings (not necessarily linear), which are noncommuting in the domain of q-normed space following the line of Meinardus.

Iterative methods for solving fractional differential equations. **Varsha Gejji** (University of Pune, India) IC/CT4220/015

Fractional differential equations have gained considerable importance due to their varied applications in visco-elasticity, electro-analytical chemistry, electrical circuits, fractional multipoles, neuron modelling and related areas in physics, chemistry and biology. Numerous problems in physics, chemistry and engineering are modelled mathematically by fractional differential equations. In the present work we study iterative methods to solve fractional differential equations. Especially

the method proposed by Adomian has proven rather successful in dealing with both linear as well as non-linear problems as it provides analytical approximate solutions of nonlinear equations without linearization, perturbation or discretization. We apply Adomian decomposition method for solving fractional differential equations in a variety of cases and provide illustrative examples.

Some recent advances in vector quasi-equilibrium problems. **Abdul Khaliq** (BGSB University Rajouri, India) IC/CT1534/005

Quasi-equilibria constitute an extension of Nash equilibria, which are of fundamental importance in the theory of non-cooperative games. The problems in this area have involved variety of mathematical methodologies. In this paper we survey recent results concerning the existence of a solution to the vector quasi-equilibrium problems. After a brief construction of the main results, direct applications are focused on the existence of solutions to vector equalibrium problems, vector quasi-variational inequality problems and vector optimization problems.

Key words and phrases: Equilibrium problems, quasi-variational inequalities, KKM-Fan theorems, fixed point theorems, upper semicontinuity

Coarsening dynamics of polymer droplets for a lubrication model with large slippage. **Georgy Kitavtsev** (Humboldt-Universität zu Berlin, Germany), Barbara Wagner (Weierstraß-Institut Berlin, Germany), Lutz Recke (Humboldt-Universität zu Berlin, Germany) IC/CT3938/052

In this talk we analyze the final stages of the dewetting process of nanoscopic thin polymer films on hydrophobized substrates using a lubrication model that captures the large slippage at the liquid-substrate interface. The final stages of this process is characterized by the slow-time coarsening dynamics of the remaining droplets. For this situation we derive a reduced system of equations from the lubrication model, using singular perturbation analysis. Such reduced models allow for an efficient numerical simulation of the coarsening process. The reduced model extends results by Glasner and Witelski [PRE (67):016302,2003] who investigated a no-slip lubrication model. Apart from collapse and collision, we identify here some new coarsening dynamics.

Asymptotic frictional contact models for piezoelectric plates. **Isabel Figueiredo** (Universidade de Coimbra, Portugal), Georg Stadler (University of Texas at Austin, USA) IC/CT2743/052

Piezoelectric materials convert mechanical energy into electric energy and vice-versa. Currently they are widely used as sensors and actuators in engineering applications, as for example aerospace, aeronautic, automotive, industrial, biomedical, underwater communications, medical imaging and control. In this talk we study new asymptotic models for thin plates with piezoelectric patches and layers that are subject to frictional contact with an obstacle. In the asymptotic process, the thickness of a three-dimensional partial differential equation model for a plate is driven to zero and the convergence of the unknowns is studied. This leads to a two-dimensional model in which mechanical displacement and electric potential are partly decoupled. Based on this two-dimensional model we present numerical examples illustrating actuator and sensor capabilities of smart devices with piezoelectric materials in the presence of obstacles.

On relative perturbation theory for block operator matrices. **Luka Grubišić** (RWTH Aachen, Germany) IC/CT3001/052

We use weakly-formulated operator equations to study perturbation problems for 2×2 operator block matrices. We allow (integro) differential operators, defined by quadratic forms, as coefficients in these weak operator equations and block operator matrices. An analysis of the "weakly formulated" Sylvester equation yields new scaling robust bounds for the rotation of spectral subspaces of a nonnegative self-adjoint operator in a Hilbert space. Our bound extends the known results of Davis and Kahan. As an example we give constructive estimates for the convergence rates of eigenvalues and eigenfunctions of the Arch model eigenvalue problem as the diameter of the thin elastic (rod like) body tends to zero. Furthermore, this prototype problem is identified as representative for the whole class of non-inhibited stiff perturbation families. This class of perturbations is characterized by a kind of inf-sup condition. Another problem which we study is bounding a perturbation of the square root of a positive self-adjoint operator. The obtained estimate is also of the relative type and we use a Sylvester like equation to solve this problem (cf. Grubišić, L.; Veselić, K. *On weakly formulated Sylvester equations and applications*, Integral Equations and Operator Theory, to appear, Preprint: http://arxiv.org/abs/math.SP/0507532). This is a joint work with K. Veselić, Hagen, Germany and J. Tambača, Zagreb, Croatia.

Geometrical optics approach to Markov-modulated fluid models. **Diego Dominici** (SUNY New Paltz, USA) IC/CT740/052

We analyze asymptotically a differential-difference equation, that arises in a Markov-modulated fluid model. In the steady state limit, the joint probability distribution of the buffer content and the number of active sources satisfies a system of $N+1$ ODEs, that can also be viewed as a differential-difference equation analogous to a backward/forward parabolic PDE. We use singular perturbation methods to analyze the problem for $N \to \infty$, with appropriate scalings of the two state variables. In particular, the ray method and asymptotic matching are used.

Modulation equations for finite-amplitude nonlinear waves in an incompressible fluid. **Warren Smith** (University of Birmingham, UK) IC/CT1117/052

A formal perturbation scheme is developed to determine original modulation equations for laminar finite-amplitude nonlinear waves in an incompressible fluid. The modulation equations comprise conservation of waves, averaged conditions for conservation of mass, momentum, and kinetic energy and the averaged projection of the Navier-Stokes equations onto the vorticity vector. The last of these modulation equations, which is related to vortex stretching, only appears in three-dimensional problems. The technique of Reynolds averaging is also employed to obtain equations for the mean velocity and pressure. The Reynolds-averaged Navier-Stokes equations correspond to the modulation equations for conservation of mass and momentum. However, the Reynolds stress transport equations are shown to be inconsistent with the other necessary modulation equations.

Derivation of the micropolar shell model. **Josip Tambača** (University of Zagreb, Croatia), Ibrahim Aganović (University of Zagreb, Croatia), Zvonimir Tutek (University of Zagreb, Croatia) IC/CT2010/052

In this work we mathematically derive a two-dimensional model of a shell-like body starting from the three-dimensional linearized micropolar elasticity.

The micropolar elasticity is a theory of solids which in contrast to the classical elasticity uses two kinematical vector fields, displacement and microrotation of the material point and two dynamical vector fields, force and couple. The material points are allowed to rotate without stretch.

The derivation of the 2-D model is based on the asymptotic expansion method with respect to the small parameter. In the present setting the small parameter is the thickness of the shell-like body; it is assumed that the thickness is much greater than the grain size. The behavior of the solution of the 3-D problem is analyzed with respect to the small parameter. The essential role in this analysis is played by the scaling of coefficients, unknowns and loads in the problem. Here the method is used without any *a priori* assumption on the scaling of the unknowns. Instead we use the set of rules, called Ansatz, inspired by the derivation of the classical plate model by Miara.

It turns out that *no scaling* is necessary in contrast to the case of classical elasticity. The form of the leading order displacement and microrotation and their correctors is derived in a classical way. Further we show that the leading term, displacement and microrotation, is the unique solution of certain 2-D problem, called the micropolar shell model. This model can be written in the form which is well defined for shells with $W^{1,\infty}$ middle surface.

We justify the model by showing that the family of solutions of the 3-D micropolar elasticity problem converge to the solution of the obtained 2-D model as the thickness of the shell tends to zero.

IC/CTS4590/05: Wavelets.

Organiser: Bin Han (University of Alberta, Canada)

lossless and near-lossless wavelet-based compression chemes. **Paco Arandiga** (Universitat de València, Spain) IC/CT3048/054

Being able to control the quality of the decoded data instead of the compression rate is suitable for applications where quality control is of utmost importance, yet we would like to be as economical as possible with respect to storage and speed of computation. In this paper we present a compression algorithm based on Harten's interpolatory framework for multiresolution that guarantees a specific estimate of the error between the original and the decoded image measured in the max-norm.

The aim of this talk is to show some of the advantages of this family of transformations when used as lossless and near-lossless image compression technique.

Riesz wavelets in Sobolev spaces. **Bin Han** (University of Alberta, Canada) IC/CT3555/054

Riesz wavelets are of interest in image processing and numerical algorithms for solving partial differential equations numerically. In this talk, we shall present a complete characterization of Riesz wavelets in a Sobolev space $H^s(R)$ for any real number s. Examples of Riesz wavelets derived from B-splines in Sobolev spaces, including the well-known hierarchical basis in the finite element method, will be given to illustrate the results. Interesting connections of Riesz wavelets to tight wavelet frames and refinable functions of exponential decay in wavelet analysis will be also addressed.

About the mathematical foundation of the Hilbert–Huang transform. **Uwe Kähler** (Universidade de Aveiro, Portugal) IC/CT3574/054

In recent years, a new tool has emerged in signal processing, the so-called Huang–Hilbert transform. In difference to classic Fourier and wavelet based methods, the Hilbert spectrum is considered instead of the Fourier spectrum, which makes the method more sensible to non-linear data but also to noise. The heart of Huang's idea is to overcome the problem of constants in the Hilbert transform by a deomposition which is called empirical mode decomposition (EMD). In this talk we will look into the mathematical foundation of the Huang-Hilbert transform and show how methods of Clifford analysis can be used to extend this transform to higher dimensions.

A numerical solution for fractional differential equations. **Hossein Parsian** (Islamic Azad University of Saveh, Iran) IC/CT390/054

In this talk, we present a numerical solution for solving fractional differential equation of order $alpha$ ($n-1 < \alpha < n$ and n is real integer). This method is based on expansion over wavelets. Wavelets constitute a family of function that constructed from dilation and translation of a single function. The mother function of Legendre wavelet is Legendre function. Legendre wavelets are defined over the interval $[0,1]$. In recent years, Legendre wavelets are used for solving differential equations, Integral equations and variational problems. In this research work, we present an operational matrix for fractional derivative. The operational matrix develops the Legendre wavelets formalism to fractional calculus. We formulate this problem in terms of left Riemann-Liouville fractional derivative. Several examples demonstrate the validity of this operational matrix.

Recovery algorithms for vector-valued data with joint sparsity constraints. **Holger Rauhut** (Universität Wien, Austria), Massimo Fornasier (University of Princeton, USA) IC/CT2021/054

Vector valued data appearing in applications often possess sparse expansions with respect to a preassigned frame for each vector component individually. Additionally, different components may also exhibit common sparsity patterns. Recently, there were introduced sparsity measures that take into account such joint sparsity patterns, promoting coupling of non-vanishing components. These measures are typically constructed as weighted ℓ_1 norms of componentwise ℓ_q norms of frame coefficients. We show how to compute solutions of linear inverse problems with such joint sparsity regularization constraints by thresholded Landweber algorithms. Further we discuss the adaptive choice of suitable weights appearing in the definition of the sparsity measures. The weights are interpreted as indicators of the sparsity pattern and are iteratively up-dated after each new application of the thresholded Landweber algorithm. The resulting two-step algorithm is interpreted as a convergent double-minimization scheme for a suitable target functional. Numerical experiments in color image restoration and distributed compressed sensing are presented.

Edge detection. **Zoraida Martínez** (Universidad Simón Bolívar, Venezuela), Carenne Ludeña (IVIC, Venezuela) IC/CT2811/054

In this work we introduce an algorithm for the automatic detection of curves in images based on curvelets (Candès and Donoho) and model selection techniques. Our main interest is detecting curves in noisy environments corrupted by nuissance line segments. Our algorithm is then applied to the automatic selection of events in seismic traces, where the determination of these events is of great importance for characterization of boreholes.

In the first part of our work we consider the method of Energy Functions with Gabor Filters. A close look at the method evidences the importance of directional information.

Motivated by the excellent results obtained with this methodology, in the second part of the work, new methods for curve detection with directional characteristics are explored, such as curvelets and their implementation by contourlets (Vetterli and Do), accompanied with model selection techniques, to obtain an optimal representation of the edges.

Several simulation results show the potential of the proposed algorithm.

Linear and nonlinear problems of active noise shielding. **Sergei Utyuzhnikov** (University of Manchester, UK), Ali Turan (University of Manchester, UK) IC/CT4274/050

The problem of active shielding of some domain from the effect of the field generated in another domain is considered. The active shielding is implemented via the placement of additional sources in such a way that the total contribution of all sources leads to the desirable effect. Mathematically, the problem is reduced to seeking certain source terms satisfying some *a priori* described requirements and belongs to the class of inverse source problems. From the application standpoint, this problem is closely related to the active shielding of noise, active vibration control and active scattering.

The solution of the problem of active shielding in the differential and finite-difference formulations is obtained under some general conditions. In contrast to many other approaches, it does not require either the knowledge of the particular Green's function or any other information on source distribution and the surrounding medium. It is also important that along with undesirable field to be shielded, a desirable field can be admitted in the analysis. The solution of the problem requires only knowledge of the total field on the perimeter of the shielded domain. The active shielding sources are obtained for both the linear and nonlinear implementations of the problem. In the case of a system governed by first-order equations, the active shielding source term is represented in the form of a single layer. Particular examples of the Helmholtz equation, acoustics equations, Maxwell equations and Euler equations are considered.

Work done in collaboration with V.S. Ryaben'kii.

Transmission operators for description and modeling of 3D scattered acoustic wavefields in layered heterogeneous media. **Milana Ayzenberg** (Norges Teknisk-Naturvitenskapelige Universitet, Norway), Arkady Aizenberg (IPGG, SB RAS, Russian Federation), Jan Pajchel (Norsk Hydro, Norway) IC/CT2395/050

We consider acoustic transmission problem in 3-D layered heterogeneous media with smooth curved interfaces. We rewrite standard statement of the problem by representing the continuity conditions for pressures and normal accelerations at the interfaces in the form of an equivalent linear system of transmission transforms. The transforms are represented by action of the transmission (reflection or refraction) convolution-type operators on the pressures and normal accelerations. Kernels of the operators are the spatial Fourier transforms of the classical reflection or refraction plane-wave coefficients. The representation is based on the fact that in a small vicinity of the interface the pressure and normal acceleration wavefields can be described by the sum of two spectral integrals generalizing the Weyl integrals. Using the Green theorem we may represent the scattered wavefield in each layer by the two surface singular integrals of Kirchhoff type. The boundary values of the integrals satisfy a modified system of the boundary integral equations. The operator of this system contains the classical surface integral propagators and transmission operators. Applying the Neumann method to the system, we obtain the boundary values as a branching sequence of multiple reflections and refractions. For modeling purposes we use a high-frequency approximation of the propagators in the form of the tip wave superposition method. For the transmission operators we use a dominant-frequency approximation in the form of effective coefficients. The effective coefficients generalize the plane-wave coefficients conventionally used in the acoustic and seismic modeling to the case of finite dominant frequency, non-plane interface and arbitrary wavefront of the incident wavefield. Application of the effective coefficients leads to amplitude and phase correction and generation of new wavefields with different kinematics, in particular the head waves. We provide results of numerical modeling of scattered wavefields.

Numerical solution of scattering problems using pseudo-differential impedance operators. **David Calvo** (Naval Research Laboratory, USA) IC/CT2034/050

Direct numerical solution of scattering problems based on integral equation or finite-element formulations are computationally costly at high frequencies. A numerical solution method is presented using high-accuracy pseudo-differential impedance operators (PIO) implemented using rational approximations. An example of a PIO is the so-called on-surface radiation condition (OSRC) method. The method can be viewed as applying a parabolic equation directly on the surface of a scatterer to provide an approximate Dirichlet-to-Neumann map for the scattered field. In contrast to past OSRCs, the use of rational approximations provides accuracy for wide scattering angles which is needed near grazing angles of incidence. Generalization to impedance operators for penetrable scatterers is presented along with applications to scattering from wavy interfaces such as the ocean bottom. Finally, the use of OSRCs as a key ingredient to iteratively solving integral equations for scattering problems is discussed (Antoine & Darbas 2005). [Work sponsored by ONR]

Reconstruction of complex obstacles from scattering data. **Mourad Sini** (RICAM Linz, Austria) IC/CT446/050

The inverse scattering for an obstacle with mixed boundary condition can be considered as a prototype for radar detection of complex obstacles with coated and non-coated parts of the boundary. We construct some indicator functions for this inverse problem using the far-field pattern directly. Based on the careful singularity analysis, these indicator functions enable us to reconstruct the shape of the obstacle and distinguish the coated and the non-coated part of the boundary. Moreover, an explicit representation formula for the surface impedance in the coated part of the boundary is also given. Our recon-

struction scheme reveals that the coated part of the obstacle is less visible than the non-coated one, which corresponds to the physical fact that the coated boundary absorbs some part of the scattered wave. Numerics are presented for the reconstruction formulas, which show that both the boundary shape and the surface impedance in the coated part of boundary can be reconstructed accurately.

This work is done in collaboration with J.J. Liu and G. Nakamura.

Asymptotic expansion of the solution of the Wigner equation near caustics. **George Makrakis** (IACM/FORTH, Greece), Evangelia Kaligiannaki (University of Crete, Greece) IC/CT4224/052

The Wigner transform is employed to reformulate the Cauchy problem for the Schrödinger equation with polynomial potentials and oscillatory initial data in configuration space, as a quantum Liouville (Wigner) equation in phase space. We explain that solutions of the Wigner equation retaining the small parameter can capture the correct Wigner function near and on the caustics, and they can therefore provide the correct energy densities at such singularities. Departing from an eigenfunction series expansion of the Wigner function, we construct asymptotic expansions of the solutions of the Wigner equation for anharmonic potentials using as a datum the Wigner function of the harmonic oscillator. Our analysis gives useful insight concerning the behaviour of the Wigner function on the caustics, and the generation of cusp caustics form the focal points of the harmonic oscillator due to anharmonicity.

Matched asymptotic expansions for the computation of the field scattered by a patch antenna. **Abdelkader Makhlouf** (INSA Toulouse, France) IC/CT3580/052

In this talk we are interested in the computation of the electromagnetic field scattered by a patch antenna (a thin coating partially covered by a perfect conductor). The classical methods (finite differences or finite elements method) require a local refinement of the mesh near the thin coating which leads to expansive computations. Moreover, the technique of equivalent boundary condition (see [1] for example) can not be directly applied due to the presence of singularities near the end of the perfect conductor.We would like to apply the technique of Matched Asymptotic Expansions[3,4] and the technique of singularity computation [2,5] to obtain an asymptotic expansion of the solution.

05: Applied Analysis, Posters

IC/PP1863/015: Existence of almost-periodic solutions of a delay-differential equation.

Presenter: Abbas Syed (IIT Kanpur, India)

This Poster is to address theoretical issues for functional differential equations, particularly delay-differential equations. Delay-differential equations are very important class of nonlinear differential equations. They arise in many problems, such as population dynamics, biological phenomena from physiology, neural networks and drug release when modeled mathematically. In this poster I also describe some of my recent research results on delay-differential equations.

IC/PP4732/050: Pseudo-differential operator theory in seismic imaging.

Presenter: Chad Hogan (University of Calgary, Canada)
Co-author: Gary Margrave (University of Calgary, Canada)
Co-author: Michael Lamoureux (University of Calgary, Canada)

Many current industrial seismic imaging algorithms rely on wavefield extrapolation, which may be accomplished using a one-way Helmholtz equation. A scalar Helmholtz equation describing wave propagation of a single frequency (ω) wave in two dimensions x, z through a scalar velocity field $v(x,z)$ is used

$$(\partial_z^2 + \partial_x^2 + \omega^2/v(x,z)^2)\phi(x,z) = 0.$$

This equation may be formally factored into two one-way wave equations, e.g. $(i\partial_z + \mathbf{B})\phi^+(x,z) = 0$. $\mathbf{B}$ is a pseudodifferential operator with symbol defined by its square such that the symbol of $\mathbf{B}$, $\Omega_{\mathbf{B}}$, when composed with itself recovers the symbol for the full Helmholtz equation. i.e. $\Omega_{\mathbf{B}}\#\Omega_{\mathbf{B}} = (\omega^2/v(x,z)^2 - \xi^2)$, where ξ is the Fourier conjugate to x.

Solutions for this operator $\mathbf{B}$ may then be used in a phase space path integral formulation to derive a computable algorithm for wavefield extrapolation (i.e. one-way marching). One asymptotic solution for the symbol $\Omega_{\mathbf{B}}$ is

$$\Omega_{\mathbf{B}}(x,z) \sim \sqrt{\omega^2/v(x,z)^2 - \xi^2}.$$

If this symbol is used, the resulting algorithm is

$$\phi^+(x, z+\Delta z, \omega) = \int_R e^{i\Delta z\sqrt{\omega^2/v(x,z)^2-\xi^2}}\hat{\phi}^+(\xi,\omega,z)e^{ix\xi}d\xi.$$

Our research is focussed in two major directions. First, we are interested in numerical improvements in this algorithm in terms of accurately evaluating this integral. Second, we are working to incorporate better asymptotic representations of the symbol $\Omega_{\mathbf{B}}$ for both the range-independent and range-dependent cases.

IC/PP409/052: Spectrum of discrete Sturm–Liouville operators via orthonormal polynomials.

Presenter: Rabah Khaldi (Annaba University, Algeria)

We study the properties of Sturm–Liouville operators using the orthonormal polynomials with respect to a measure on the segment $[-1,1]$ perturbed by an infinite sequence of point masses. Note that the properties of a discrete Sturm–Liouville operators are transformed in a defined way to the continuous Sturm–Liouville operator that is of fundamental importance in mathematics and physics. The spectrum of discrete Sturm–Liouville operators in a particular case have been already studied in [2].

IC/PP937/052: The Bogolubov generating functional method in statistical physics and collective variables transform within the grand canonical ensemble.

Presenter: Anatoliy Prykarpatsky (WMS AGH/IAPMM, Poland)
Co-author: Nikolay Bogolubov (jr.) (MI Russian Academy of Science)

We show that the N.N. Bogolubov generating functional method [1] is a very effective tool for studying distribution functions of both equilibrium and non equilibrium states of classical many-particle dynamical systems. Let a large system of one-atomic and spinless) bose-particles with a fixed density in a volume be specified by a quantum-mechanical Hamiltonian operator, consisting of the kinetic energey operator and of a two-particle potential energy operator, allowing a partition into a short range potential of the Lennard–Johns type and a long range potential of the Coulomb type. Making use of the second quantization representation, the Hamiltonian operator can be re-written as the operator acting in a suitable Fock space with the standard scalar product, being constructed of the standard creation and annihilation operators. Introduce the Bogolubov generating functional:

$$\mathcal{L}(f) := (\Omega, \exp[i\rho(f)]\Omega) \tag{1}$$

for any *test* Schwartz function $f \in S(\mathbb{R}^3;\mathbb{R})$, where $\rho(f) := \int_{\mathbb{R}^3} \mathrm{d}^3x\, f(x)\,\rho(x)$, then for n-particle distribution function one can get the expression:

$$F_n(x_1,x_2,...,x_n) =: \frac{1}{i}\frac{\delta}{\delta f(x_1)}\frac{1}{i}\frac{\delta}{\delta f(x_2)}...\frac{1}{i}\frac{\delta}{\delta f(x_n)} : \mathcal{L}(f)|_{f=0}\,. \tag{2}$$

The following main propositions are proved.

Proposition *The functional (1) satisfies [1,2] the following functional Bogolubov type equation:*

$$[\nabla_x - i\nabla_x f(x)]\frac{1}{i}\frac{\delta\mathcal{L}(f)}{\delta f(x)} = -\beta\int_{\mathbb{R}^3}\mathrm{d}^3y\nabla_x V(x-y) : \frac{1}{i}\frac{\delta}{\delta f(x)}\frac{1}{i}\frac{\delta}{\delta f(y)} : \mathcal{L}(f)\,,$$

with the expression

$$\mathcal{L}(f) = Z(f)/Z(0), \quad Z(f) := \exp[-\beta V(\delta)]\mathcal{L}_0(f)\,,$$
$$\mathcal{L}_0(f) = \exp(z\int_{\mathbb{R}^3}\mathrm{d}^3x\{\exp[if(x)]-1\})$$

being its exact functional-analytic solution.

Proposition *Let the Bogolubov-type generating functional $\mathcal{L}(f)$, $f \in S(\mathbb{R}^3;\mathbb{R})$, represented analytically as a series of graph-generated functionals, satisfy the following conditions: 1. continuity with respect to the natural topology; 2. positivity; 3. symmetry and normalization conditions; 4. translational-invariance; 5. cluster condition or, equivalently, the Bogolubov correlation decay; 6. the equilibrium density condition.*

06: Optimization, Minisymposia

IC/MP341/010: Advances in interior point methods.

Organiser: Florian Potra (National Institute of Standards and Technology, USA)

The advent of interior-point methods has revolutionized the field of mathematical programming. Over the past two decades algorithms and software for linear programming based on interior-point methods have become quite sophisticated, while extensions to more general classes of problems, such as convex quadratic programming, semidefinite programming, and nonconvex and nonlinear problems, have reached varying levels of maturity. The minisymposium speakers will present new advances in this field, focussing on the relation between different formulations of the cone programming problem and the relation between computational complexity and the geometrical properties of the central path, The impact of the theoretical results on the design of more efficient algorithms will be emphasized.

First-order primal–dual algorithms for cone programming. **Renato Monteiro** (Georgia Institute of Technology, USA) IC/MT1610/010

In this talk, we consider the general cone programming problem, and propose primal-dual convex (smooth and/or nonsmooth) minimization reformulations for it. We then survey first-order methods suitable for solving these reformulations, namely, Nesterov's optimal method, Nesterov's smooth approximation scheme, and Nemirovski's prox-method, and propose a new variant of Nesterov's optimal method which has outperformed the latter one on our computational experiments. We also derive iteration-complexity bounds for these first-order methods for solving the proposed primal-dual reformulations. The performance of the variants obtained in this way is then compared using a set of randomnly generated linear programming (LP) and semidefinite programming (SDP) instances. We also compare the approach based on the variant of Nesterov's optimal method with the low-rank method proposed by Burer and Monteiro.

Interior point methods for linear complementarity problems. **Florian Potra** (National Institute of Standards and Technology, USA) IC/MT2666/010

We present a class of interior point methods for solving general linear complementarity problems over symmetric and nonsymmetric cones that admit self-concordant logarithmically homogenous barriers. The methods use adaptive long steps to produce iterates in a wide neighborhood of the central path. We present results on the computational complexity of the algorithms from this class, and give sufficient conditions under which the duality gap converges superlinearly to zero. We also give sufficient conditions for the convergence of the iterates produced by the interior point methods under consideration.

Geometric structure of the central trajectories and complexity of interior-point. **Takashi Tsuchiya** (Inst. of Statistical Mechanics, Tokyo, Japan) IC/MT2668/010

Sonnevend, Stoer and Zhao introduced a curvature integral of the central trajectory for LP which provides an approximation to the iteration-complexity of interior-point algorithms. Monteiro and Tsuchiya studied the curvature in relation with the Vavasis–Ye's layered-step interior-point algorithm, and established an interesting property that the total curvature of the central trajectory is bounded by $O(n^{3.5}L_A)$, where n is the number of nonnegative variables and L_A is the imput bit length of A. In this talk, we discuss further implications and extensions of this result.

IC/MP309/010: Applied topological methods.

Organiser: Victor Zvyagin (Voronezh State University, Russian Federation)

The minisymposium is intended to present a large variety of applications of contemporary topological methods to some problems, such as: control theory, hydrodinamics, variational inequalities. In this perspective we will present latest applications of the topological degree theory and the coincidence index to some optimization and controllability problems for control systems governed by differential inclusions in finite and infinite-dimensional spaces. The other applications are connected with the finding of optimal feedback control in problems arising from models of non-Newtonean visco-elastic fluids. Also we will describe topological methods which are applicable for solving the problems described by variational inequalities and their applications in optimization and mathematical economics.

Investigation of boundary value problems for certain models of non-Newtonian hydrodynamics. **Victor Zvyagin** (Voronezh State University, Russian Federation) IC/MT546/010

The report devoted to the description of contemporary investigations in the field of new boundary and initial-boundary value problems for stationary and evolution equations of non-Newtonean hydrodynamics. In particular, we present the investigation of the following problems:

1. The solvability of boundary value stationary problem with slip for the model of electro-rheological fluid;
2. The investigation of initial-boundary value problem in the model of motion of viscoelastic fluid with JeffreyŠs constitutive relation;
3. The description of trajectory and global attractors for the Jeffreys model;
4. The investigation of the initial-boundary value problem for the Voight model in the case of varying domain;
5. The study of some optimal feedback control problems in the Voight model.

All results are obtained by the following approximate-topological method. At first we give the operator treatment of the considered problem in the form of the operator equation in some functional space which is appropriate for this problem. For this equation we suggest a family of auxiliary operator equations defined in a functional space which has (as a rule) better topological properties. Further, the application of some versions of the topological degree theory in Banach spaces and *a priori* estimates allow us to obtain the solvability of these auxiliary equations. At last, the passage to the limit (in the sense of distributions theory) in the sequence of solutions of auxiliary equations, based on *a priori* estimates of these solutions in the initial functional space, leads to the solution of the principal operator equation and, hence, to the solution of the initial problem.

Relative topological degree and variational inequalities. **Pietro Zecca** (Università di Firenze, Italy) IC/MT1686/010

We give a definition of relative topological degree for multimaps which are composition of approximable multimaps and continuous maps. Then, we apply this notion to prove an existence result for variational inqualities of Stampacchia's type of the form:

(S) Let V be a normed space, $K \subset V$ a nonempty, closed convex set, $h \in V$ a given element, $T : V \multimap V$ a multimap.

Find $x \in V$, $y \in T(x)$ such that

$$\langle v - x, y \rangle \geq \langle v - x, h \rangle \quad \forall v \in K.$$

Some applications to optimization problems are considered.

Attractors of boundary-value problems for motion equations of a few viscoelastic media models. **Dmitry Vorotnikov** (Voronezh State University, Russian Federation) IC/MT968/010

We shall describe sufficient conditions for existence of minimal uniform trajectory attractors and uniform global attractors of evolution equations which do not have uniqueness of Cauchy's problem. Unlike the earlier results (e.g. [1]), here it is not assumed that the symbol space of an equation is a compact metric space and that the family of trajectory spaces corresponding to this symbol space is translation-coordinated or closed in any sense. We shall also discuss the case of autonomous equations, which is simpler than the general case. In this situation any invariance of the trajectory space of an equation is not required. Then we shall show some results on properties and structure of the attractors. Application of this theory allows us to construct attractors for weak solutions of the boundary value problems for the motion equations of an incompressible viscoelastic medium with the Jeffreys constitutive law [2] and more complicated constitutive laws.

A significant part of the talk will be based on works [3],[4]. The research was partially supported by grants 04-01-00081 (RFBR), VZ-010-0 (Ministry of Education and Science of Russia and CRDF) and MK-3650.2005.1 (Grant of President of Russian Federation).

Multi-valued variational inequalities and applications. **Irene Benedetti** (Università di Modena e Reggio Emilia, Italy) IC/MT2189/010

This talk deals with applications of multivalued variational inequalities of Stampacchia's type to a boundary value problem for a PDE of the form

$$\begin{cases} -\Delta u + f \in \Psi(u), & x \in \Omega \\ \dfrac{du}{dn} \geq 0, & x \in \partial\Omega \end{cases}$$

where $\Omega \subset \mathbb{R}^n$ is a bounded domain with a regular boundary $\partial\Omega$, $u \in W^{1,2}(\Omega, \mathbb{R})$, $f : \mathbb{R}^n \to \mathbb{R}$, $\Psi : W^{1,2}(\Omega, \mathbb{R}) \multimap W^{1,2}(\Omega, \mathbb{R})$ are given function and multifunction.

Existence and uniqueness of a weak solution for the model of Foight. **Mikhail Turbin** (Voronezh State University, Russian Federation) IC/MT990/010

In connection with the presence of a large number of physics applications many papers recently attend to the study of liquid motion in domain with time-dependent boundary. In the majority of works in the given direction the resolvability of Navier–Stokes equations in similar domains is investigated. Namely in works [1,2,3] various statements of initial boundary value problems have been offered and existence of strong and weak solutions and some regularity problems have been investigated. However Nuton model of liquid motion does not describe the motion of liquids possessing relaxation or retardation properties for example of various gels and emulsions.

We study the initial-boundary value problem for Foight mathematical model in domains with time-dependent boundary is investigated. This model describes the motion of a liquid to which needs time to begin a motion under the action of suddenly applied force.

The main result is the existence and uniqueness theorem of the weak solution for this initial boundary value problem. For the proof we consider an approximation problem and show its resolvability using the topological degree theory and *a priori* estimates of solutions. Then we show that the solution of this approximating problem converges to the solution of our starting problem.

Mathematical modelling of slipping of nonlinear-viscous fluids. **Mikhail Kuzmin** (Voronezh State University, Russian Federation) IC/MT3998/010

The mathematical model of non-stationary (and stationary) movement of nonlinear-viscous fluids under conditions of slip on the boundary is considered. Various types of conditions of slip are considered. Theorems of existence of initial-boundary (and boundary) problems describing movement of nonlinear-viscous fluids under condition of slip on the boundary are proved. For this purpose the approximating-topological method is used.

Differential inclusions on Riemannian manifolds. **Andrei Obukhovskii** (Voronezh State University, Russian Federation) IC/MT3999/010

I consider second-order differential inclusions on a Riemannian manifold with Carathéodory and lower semicontinuous right hand sides. Several existence theorem for solutions of two-point boundary value problem are proved that are interapted as controllability of special mechanical systems with control on nonlinear configuration spaces. As an application a statement of controllability under extreme values of controlling force is obtained.

IC/MP339/015: Industrial organization and game theory.

Organiser: Alberto Pinto (Universidade do Porto, Portugal)

The Stackelberg (1934) model is one of the most widely used models in industrial organization for analysing firms' behaviour in a competitive environment. It studies the strategic situation where firms sequentially choose their output levels in a market. The question we ask is: Do first movers really have strategic advantage in practice? The belief of first-mover advantage was widely held among entrepreneurs and venture capitalists, but is now questioned by numerous practitioners. Several research papers focus their attention in giving answers to such question. Liu (2005) studied the effects of the market demand uncertainty to explain the advantages and disadvantages of being the leading firm.

The Cournot competition with R&D investment programs consists of two subgames in one period of time. The first subgame is an R&D investment program where both firms have initial production costs and choose, simultaneously, the R&D investment strategies to obtain new production costs and at what moment of the period is achieved the reduction. We present new deterministic and stochastic dynamics on the production costs of Cournot competitions using Nash equilibrium of R&D investment strategies with and without uncertainty of the firms. At every period of time, the firms invest in R&D projects to reduce their production costs. The R&D strategies of the firms give rise to deterministic and stochastic dynamics on the production costs characterizing the duopoly competition along the periods of the time. We studied the effect of the dynamics in the profits and persistence of the firms in the market.

Scientific objectives: To extend Liu's results by focus not only on the effects of the market demand uncertainty, but also on product differentiation, to explain the advantages and disadvantages of being the leading firm. To extend the results on the previous item to other models, including private information, signalization, and international competition with subsidies and tariffs. To prove analytically the empirical results already obtained. To extend the results on the previous item to other models, including private information, signalization, and international competition with subsidies and tariffs.

An approach to different voting rules from cooperative games with alternatives. Discussion case: the Catalonia parliament. **Antonio Magana** (Universitat Politècnica de Catalunya, Spain), Francesc Carreras (Universitat Politècnica de Catalunya, Spain) IC/MT2195/015

Classical cooperative (simple) games cannot cope with certain subtleties of voting rules. The structure of such a game, given by a list of *winning* coalitions, doesnŠt specify the inputs for voters, the feasible outputs and the mechanism that transforms any set of inputs in a well defined output. Roughly speaking, these games merely describe the case where a proposal is faced to a status quo or the case where a proposal has to be chosen among several ones by absolute or qualified majority. Thus, e.g., the abstention possibility or the decision-making by the usual relative majority rule cannot be represented this way. As a consequence, when applied to these games, classical power measures as the Shapley–Shubik index may well fail to reflect accurately the strategic position of the voters. This is an important limitation in the analysis of shareholder corporations, political organisms and voting bodies in general.

Games with alternatives provide a wider framework that allows us to describe voting rules precisely. The natural extension of the Shapley–Shubik index to this class of games, axiomatically founded, becomes an interesting tool for a numerical evaluation of the strength of each voter in any system. These ideas will be illustrated on a real life numerical example, the Catalonia Parliament. By considering different voting rules scheduled by the Parliament By-Laws, modelling them by means of suitable games with alternatives, and applying the extended Shapley–Shubik index, remarkable differences between the voters will be discovered that depend on the voting procedure considered.

Asymmetric dynamic price competition with uncertainty. **Fernanda Ferreira** (Instituto Politecnico do Porto, Portugal), Flávio Ferreira (Instituto Politecnico do Porto, Portugal), Miguel Ferreira (Universidade do Porto, Portugal), Alberto Pinto (Universidade do Porto, Portugal) IC/MT3561/015

In this paper, we consider a price competition in a duopoly with substitutable goods, linear and asymmetric demand and with unknown costs. One of the firms is a leader: it chooses first the price p_1 for its product; and the other firm is a follower: it chooses the price p_2 for its product after have observed the price p_1. We suppose that each firm has two different technologies, and uses one of them following a certain probability distribution. The use of either one or the other technology affects the unitary production cost. We show that there is exactly one perfect Bayesian equilibrium for this game. We analyse the variations of the expected market prices and the expected profits over the probability distributions' parameters, and also over the demand parameters. We show that for production costs with the same average, the expected profit of the leading firm increases with the variance of its production costs, and the expected profit of the follower increases with the variance of both production costs.

Two main utility-sharing methods in joint business: a discussion. **Francesc Carreras** (Universitat Politècnica de Catalunya, Spain), Rafel Amer (Universitat Politècnica de Catalunya, Spain), Antonio Magana (Universitat Politècnica de Catalunya, Spain) IC/MT1029/015

The proportional rule has a long tradition in collective problems where utility (costs, profits, savings) is to be shared among the agents. While its apparent simplicity may be a reason for applying it in pure bargaining affairs, where only the whole and the individual utilities exist, it seems much more questionable in case of general cooperative problems, where all marginal contributions should matter.

The axiomatic foundation proposed by Shapley, when introducing the value notion for cooperative games, allows us to discuss positive and negative aspects of the proportional rule and compare it with the Shapley value.

Shapley stated the general problem of finding a value; i.e., a rule for allocating to each cooperative game a payoff vector for its players. He imposed four reasonable conditions a value

should satisfy: efficiency, null player property, symmetry, and additivity. Moreover, he proved an existence and uniqueness theorem: there is one and only one rule that fulfils these requirements.

In this framework, the proportional rule can be checked and compared with the Shapley value. The proportional rule:

(a) applies only on a restricted domain of games;
(b) ignores almost all marginal contributions of the players, so that valuable agents in a cooperative affair may well be not rewarded;
(c) exhibits a hardly justified double discriminatory level;
(d) coincides with the Shapley value on additive or symmetric games;
(e) satisfies efficiency, the null player property and symmetry in its restricted domain;
(f) fails to satisfy additivity, which is not merely a standard mathematical property but one of great interest for practitioners since, from the lack of additivity, serious inconsistencies derive when applying the rule to related cost and saving problems, purchasing pools making accumulated orders, or sharing costs in simultaneous supplies.

IC/MP339/015: Industrial organization and game theory. #2

Emergence of long-run behaviours in a game-theoretic setting with host and guest populations: residents and tourists. **Elvio Accinelli** (Universidad Autonoma de San Luis Potosi, Mexico) IC/MT4096/015

In this paper we model tourism development in the framework of multi-population dynamics and analyze the time pattern of its impact as the evolution of the interaction between two populations feeding over the same space-resource. Each population might be structured in two (or more) clubs with variable membership, a club being a group of population members sharing social and economic interests as to the management of the relevant resource. Thus, each club has in principle a different set of strategies as to protection and valorization of broadly defined environmental resources at the tourist destination. Such resources share some of the characteristics of the so called commons. To represent such peculiar situation, we use Evolutionary Game Theory, in particular as is applied to the theory of evolution of interacting structured populations. In one such game, one strategy will be characterized as conservative and its alternative as depredative. Interaction between different strategies and the corresponding playing clubs gives rise to a rich dynamics, as some joint outcomes are inherently unstable, as is known, others being evolutionary stable. Such situation will be modeled by a version of the well known replicator dynamics, to emphasize its evolutionary nature.

Strategic trade policy and signalling costs with differentiated goods. **Flávio Ferreira** (Instituto Politecnico do Porto, Portugal), Fernanda Ferreira (Instituto Politecnico do Porto, Portugal), Alberto Pinto (Universidade do Porto, Portugal) IC/MT853/015

We consider two Cournot firms, one located in the home country and the other in the foreign country, producing differentiated goods for consumption in a third country or market. At the beginning of period 1, the home government commits to a subsidy for the home firm. At this stage neither the home government nor the foreign firm knows the cost of the home firm, though it is common knowledge that it has either low (c_L) or high (c_H) costs with Prob$(c = c_L) = \phi$. Marginal cost of the foreign firm is common knowledge. At the end of the first period, both firms make their output decisions simultaneously, to maximise profits. After observing the output levels of the home firm, the uninformed agents update their beliefs about the costs of the home firm. Let $\phi(q_1)$ be the common updated probability assessment, where q1 is the first-period output of the home firm. At the beginning of the second period, based on the updated beliefs, $\phi(q_1)$, the home government sets its policy instrument level to maximise welfare. Given the subsidy level chosen by the home government and given the updated beliefs of the foreign firm, the two firms choose period 2 outputs to maximise profit.

Donald Wright (1998) analysed the case of homogeneous goods, and showed that, in such case, the optimal subsidy is lower when the home firm signals costs compared to the case when the firm does not. In our work, we show that if the goods are differentiated, the optimal subsidy can be higher when the home firm signals costs compared to the case when the firm does not.

Firms signaling earnings. **Nuno Azevedo** (Ponte de Lima, Portugal), Alberto Pinto (Universidade do Porto, Portugal) IC/MT860/043

The signaling models are under criticism as the empirical literature found weak evidences supporting a central prediction: the positive relationship between changes in dividends and changes in earnings. In the absense of single-crossing property, signaling is possible, and changes in dividens and changes in earnings can be positively or negatively related.

Optimal investments in repeated Cournot competition. **Alberto Pinto** (Universidade do Porto, Portugal), Bruno Oliveira (Universidade do Porto, Portugal), Fernanda Ferreira (Instituto Politecnico do Porto, Portugal), Flávio Ferreira (Instituto Politecnico do Porto, Portugal), Miguel Ferreira (Universidade do Porto, Portugal) IC/MT859/015

We present deterministic dynamics on the production costs of Cournot competitions, based on R&D investment strategies of the firms. In this paper, we focus our attention in the drastic long term economic effects resulting from starting with different initial production costs. We find three distinct economic regions, in the space of all possible initial production costs for both firms, consisting of a no survival, weak survival and recovery behavior. The survival boundary for firm F_1 is the boundary between the no survival and weak survival regions for firm F_1, and is characterized by the stable manifold of the "last" no survival equilibrium. The recovery boundary for firm F_1 is the boundary between the weak survival and survival regions for firm F_1, and is determined by the stable manifold os the "last" weak equilibrium. This characterization of the economic boundaries through the stable manifolds of equilibrium points shows a nice interplay between dynamics and economics. The recovery region for firm F_1 is a set of initial production costs for both firms in which the firm F_1 is with initial production costs worse than the firm F_2, but after some periods of time the firm F_2 is able to diminish the gap between the two firms and both firms approach production costs favourable to both firms. The weak survival region of firm F_1 corresponds to initial production costs where the gap between the initial production costs of the firms is greater than in the survival region. Along the time the gap increases and the production costs of the firms approach a region of production costs which are unfavourable to firm F_1 and favourable to firm F_2.

IC/MP262/015: Applied mathematics in Latin America: part 2.

Organiser: Domingo Tarzia (CONICET - Univ. Austral, Rosario - ARGENTINA)
Co-organiser: Julio Claeyssen (Universidade Federal do Rio Grande do Sul, Brazil)

The goal of this minisimposium (Part 2) is to give an overview of the state of the art in diferent subjects related to partial differential equations, optimization and optimal control that are under current development in several regions of Latin America.

Convergence of boundary-optimal controls in mixed elliptic problems. **Claudia Gariboldi** (Universidad Nacional de Río Cuarto, Argentina), Domingo Tarzia (CONICET - Univ. Austral, Rosario - ARGENTINA) IC/MT599/015

We consider the problems P and P_α respectively with mixed boundary conditions (for each parameter $\alpha > 0$):

$$-\Delta u = g \; in \; \Omega \quad u|_{\Gamma_1} = b \quad -\frac{\partial u}{\partial n}|_{\Gamma_2} = q$$

and

$$-\Delta u = g \; in \; \Omega \quad -\frac{\partial u}{\partial n}|_{\Gamma_1} = \alpha(u-b) \quad -\frac{\partial u}{\partial n}|_{\Gamma_2} = q$$

where $g \in L^2(\Omega)$, $q \in L^2(\Gamma_2)$ and $b \in H^{\frac{1}{2}}(\Gamma_1)$.
We consider q as a boundary control variable for suitable cost functionals J and J_α which depend on the solution of problems P and P_α respectively for each positive $q \in L^2(\Gamma_2)$. We formulate boundary optimal control problems. We prove the existence and uniqueness of the boundary optimal controls q_{op} and q_{op_α} (for each parameter $\alpha > 0$) and we give the optimality conditions as complementary conditions in terms of the optimal controls and the optimal adjoint states $p_{q_{op}}$ and $p_{q_{op_\alpha}\alpha}$ of the systems, respectively. We also prove that the optimal control q_{op_α} and its corresponding system state $u_{q_{op_\alpha}\alpha}$ and adjoint state $p_{q_{op_\alpha}\alpha}$ are strongly convergent to $q_{op}, u_{q_{op}}$ and $p_{q_{op}}$ in $L^2(\Gamma_2), H^1(\Omega)$ and $H^1(\Omega)$ respectively when $\alpha \to \infty$.

The HIV-1 dynamics as an optimization process. **Federico Biafore** (Universidad Nacional de San Martín, Argentina), DAttellis Carlos (Universidad Favaloro, Argentina) IC/MT3733/036

The dynamics of the HIV-1 infection can be represented by means the use of predator-prey models that represent the interaction of the virus and the host immune system. The values of the parameters of this models are obtained using regression techniques from experimental data and/or adjusted by the researcher with the purpose of reproducing the infection dynamics observed in the clinical practice. The aim of this work is to try to reproduce the dynamics of the infection expressing the infection rate parameter of the employed model as a variable that evolves according to an optimization approach. The Maximum Pontryagin Principle is applied. The preliminary results suggest the possibility to explain some aspects of the HIV-1 dynamics as an optimization process involving a cost function.

An improved scheme for accelerating the convergence of the simulated annealing algorithm applied to real-world problems. **Adriana Verdiell** (Universidad Nacional del Sur, Argentina), María Maciel (Universidad Nacional del Sur, Argentina), Marta Vidal (Universidad Nacional del Sur, Argentina) IC/MT758/015

When formulated in mathematical terms, the problem of zoning a protected natural area subject to both box and spatial constraints results in a large combinatorial optimization problem belonging to the NP-hard class. These facts suggest the need to apply a heuristic approach. In this contribution a new proposal to decrease the control parameter, known as temperature, in the simulated annealing algorithm is presented. The strategy is based on that proposed by Lundy and Mees, and developed in order to decrease the running time of the algorithm applied to large scale problems. When applied to solving small-size simulated problems, results were indistinguishable from those obtained via an exact, enumerative method.

A coarse-scale zoning of Talampaya National Park (Argentina) rendered maps remarkably similar to those produced by subject area experts using a non-quantitative consensus-seeking approach. Results are encouraging and show particular potential for the periodical update of zoning of protected natural areas. Such a capability is crucial for application in developing countries where both human and financial resources are usually scarce but still critical for updating zoning and management plans.

Numerical approximation of a variational problem. **Lisandro Parente** (Universidad Austral de Rosario, Argentina), Laura Aragone (Universidad Austral de Rosario, Argentina), Pablo Lotito (UNICEN de Buenos Aires, Argentina), Gabriela Reyero (Universidad Nacional de Rosario, Argentina) IC/MT585/015

We consider a variational analysis problem which generalizes the problem of optimal Lipschitz extension. More precisely we consider the minimization of a functional given by $J(u) = \operatorname{ess\,sup}_{x\in\Omega} f(x,u,Du)$ where $u \in W^{1,\infty}_g = \{v \in W^{1,\infty} : v = g \text{ on } \partial\Omega\}$ and $\Omega \subset \mathbb{R}^n$ is bounded. In the particular case that $f(x,u,Du) = \|Du\|$ the problem becomes the search for the Lipschitzian extension of g with minimum Lipschitz constant.

This work deals with the numerical approximation of the solution. The optimality conditions of this problem are given by the Aronson-Euler equation. One approach could be to look for a viscosity solution of these equations. Instead, given the quasiconvexity of the data functions, we can solve it as a finite dimension optimization problem obtained through the discretization of the original one.

The obtained optimization problem can be nonlinear depending on the function f. In order to solve it we penalize the restrictions and consider the system of nonlinear equations given by the optimality conditions. We show that the penalized solution converges to the solution of the discretized problem, and we solve the nonlinear equation system by a Newton type method.

We present results on the convergence rate of our numerical method that depends on the regularity of the functional. We show some numerical examples.

IC/MP204/061: Multidisciplinary optimization in simulation-based design.

Organiser: Natalia Alexandrov (NASA Langley Research Center, USA)

Complex engineering design optimization problems, especially problems governed by computational simulations, rarely lend themselves to straightforward formulation and solution by conventional methods of nonlinear programming. Multidisciplinary optimization (MDO) comprises methods from computational optimization, disciplinary and process modeling, and various engineering disciplines that govern different aspects of a system being designed. In this minisymposium, we dis-

cuss the challenging analytical and computational aspects of multidisciplinary simulation-based design problems, as well as techniques for solving some classes of these problems. The techniques include exploiting problem structure, alternative problem formulation, the use of various approximations and multi-physics models to address the cost of expensive simulations (e.g., the solution of differential equations), and the use of computational infrastructures. Applications that serve to illustrate the use of methods include aerospace problems and ship-design problems.

Multilevel methods for PDE-constrained optimization. **Natalia Alexandrov** (NASA Langley Research Center, USA) IC/MT1457/061

We examine an approach to the design of complex systems governed by coupled PDE. The term multilevel refers to the optimization problem formulation, the solution algorithm and the use of several layers of models in representing a particular discipline at various stages of design. We investigate analytical and computational properties of the approach and examine a numerical demonstration.

High-fidelity modeling and parallel architecture in the simulation-based design of a fast multi-hull ship. **Daniele Peri** (INSEAN, Italy), Antonio Pinto (INSEAN, Italy), Giovanni Fasano (INSEAN, Italy), Emilio Campana (INSEAN - Italian Ship Model Basin, Italy) IC/MT362/061

Design activities of marine veichles usually involve many different disciplines, highly interacting each other. In this context, design optimization meets great difficulties due to the requested effort. Fast, multihull ships are the today's trend for displacement marine vehicles. However, if the space between the hulls is small, interference effects arise, generated both by the interaction between the boundary layers of the two hulls and by the two wave systems interaction. This leads to an increase in the total resistance of the ship that has to be minimised. Furthermore, also the effect of the real pitch angle and draught the ship has once at speed must to be accounted for. As a consequence, expensive RANS solvers, with free-sufrace capturing capacities and also able to handle the free-running model, are mandatory, which implies a dramatic increase of the total cost of the optimization cycle: to this aim, a number of different techniques have been developed in the field of Multi-Objective Design Optimization in order to alleviate the computational cost of the whole optimization cycle. In this paper, a real-life optimization problem for the shape optimization of a fast catamaran ship is tackled. Parallel architectures, in conjunction with metamodel techniques are applied. A mixed strategy, with the use of two different derivative-free global optimization algorithms, is presented. Preliminary results demonstrate the great improvements the designer may obtain by controlling the different elements of the interference between the hulls.

Particle-swarm optimization method in the MDO of a sail-boat keel. **Giovanni Fasano** (INSEAN, Italy), Emilio Campana (INSEAN - Italian Ship Model Basin, Italy), Daniele Peri (INSEAN, Italy), Antonio Pinto (INSEAN, Italy) IC/MT375/061

We consider the use of a class of global optimization techniques, for the minimization of a nonconvex function, arising from a ship design real application. The latter problem comes up in a large number of practical ship design and naval engineering contexts, where different disciplines must be often coupled, encompassing hydrodynamic and structural problems. This scenario requires the use of specific multidisciplinary formulations, where the approaches with standard mathematical programming methods could be unsuitable. MultiDisciplinary formulations require indeed the combined use of effective Optimization techniques (MDO), in order to solve highly nonconvex and possibly nondifferentiable problems. We propose in this work the use of an optimization method, for the design of a sailboat keel. The formulation of the latter problem provides a global optimization application, whose solution can be hardly tackled with standard techniques, which require the continuous differentiability of the objective function. We applied a modified Particle Swarm Optimization (PSO) method, which owes its popularity to the reasonable balance it provides between the overall computational cost and the quality of the final solution. Despite some recent variants, the algorithms in the PSO class are mainly heuristics, whose progress may be eventually very slow. The latter drawback can be explained by observing that these techniques completely disregard any condition related to first order information on the objective function. We first give a numerical experience which proves the computational efficiency of our proposal. Then we prove that in a linesearch framework and under mild assumptions, our proposal retains the global convergence to stationary points.

A framework for automatic implementation of MDO architectures. **Joaquim Martins** (University of Toronto, Canada) IC/MT1785/061

A new MDO framework has been developed in Python to provide a platform for comparisons relating the performance of various MDO architectures. The framework eliminates the need for problem reformulation when solving MDO problems in multiple architectures. Once a problem has been described, the implementation in any architecture is automatic. In addition to providing a performance comparison of the more common architectures, the modular design of the framework allows rapid testing of newly developed architectures. Results generated from this study provide a strong foundation for identifying the performance trends of various architectures with a variety of problem classes. It also serves to verify the performance and potential of those tested.

IC/MP3439/061: Optimal control of industrial applications modelled by ODEs and PDEs.

Organiser: Kurt Chudej (Universität Bayreuth, Germany)
Co-organiser: Christof Büskens (Universität Bremen, Germany)

Optimization and optimal control of huge realistic models of industrial applications are challenges for applied mathematiciens. Although the applications come from different fields like container cranes, cars and power plants, the mathematical problems are very similiar. A generalization of theory and algorithms is necessary to cope with the enormes complexities of the models.

Hybrid solution of bilevel optimal-control problems. **Matthias Knauer** (Universität Bremen, Germany), Christof Büskens (Universität Bremen, Germany) IC/MT3454/061

The industrial application of container cranes requires the calculation of time and energy optimal trajectories, so that the crane system comes to be at rest at a predefined location. Additionally, it has to be ensured that the crane system can be brought to rest at a free but admissible location within a given time from any state of the trajectory.
This task can be considered as a bilevel optimal control problem: In this extension to classical optimal control problems, additional constraints are considered which depend on the optimal solutions of secondary optimal control problems.

By evaluating the necessary conditions for the secondary optimal control problems, the bilevel structure can be reduced to a single level.

Advanced optimal feedback control for tracking of real-life applications. **Christof Büskens** (Universität Bremen, Germany), Ramona Stach (Universität Bremen, Germany) IC/MT3451/061

Calculating the open-loop solution of an optimal control problem is just the first step to cope with the practical realization of real life applications. Feedback controllers, like the classical Linear Quadratic Regulator closed-loop controller (LQR), are needed to compensate perturbations appearing in reality. Although these controllers have proved to be a powerful tool in many applications and to be robust enough to countervail most differences between simulation and practice, they are not optimal if disturbances in the system data occur. If these controllers are applied in a real process, the possibility of data disturbances force recomputing the feedback control law in real-time to preserve stability and optimality, at least approximately. For this purpose, a numerical method based on the parametric sensitivity analysis of nonlinear optimization problems is suggested to calculate higher order approximations of the feedback control law in real-time. Using this method, the optimal controller can be adapted within a few nanoseconds on a typical personal computer. The method is illustrated by the adaptive optimal control of the classical inverted pendulum and a crane system.

Model reduction in laser welding. **Verena Petzet** (Universität Bayreuth, Germany), Hans Josef Pesch (Universität Bayreuth, Germany) IC/MT3462/061

Laser welding is a modern joining technique for new metallic materials particularly aluminum alloys. However, there is a high risk of hot cracking. Therefore, the aim is to avoid this undesirable effect caused by several processes during the solidification. For modeling process there are three main aspects which has to be considered: The thermodynamical, the mechanical and the metallurgical effect by which the arising of the opening displacement caused by transverse tensile strains can be described. Because of the high complexity of this physical process a model reduction in the mathematical model has to be done.
After that formulation a method can now be applied to prevent hot cracking. One possibility is to use the so called multi-beam technique. Thereby, additional laser beams are imposed to compensate for the strain induced by the main laser beam. Hereby, it is important to determine the optimal position, size and power of the additional laser beams in order to prevent hot cracking. Mathematically, this leads to a constraint nonlinear optimization problem where amongst other constraints a partial differential equation has to be solved.

Optimal control of a servo drive system with Coulombic friction and state constraints. **Helmut Maurer** (Universität Münster, Germany), Oliver Zirn (Universität Gießen, Germany) IC/MT4174/061

We consider a servo drive system that represents a typical electrodynamic actuator. As such an actuator is very common for loudspeakers, it is called a voice-coil-motor. The basic dynamical model comprises five ODEs for the motor, resp., load mass positions and velocities as well as the coil current. The control function is given by the voltage input. The system involves static Coulombic friction that causes discontinuities in the dynamic equation for the motor mass velocity. We study both time-minimal and energy-minimal controls and show that time-minimal controls are of bang-bang type. We present numerical methods for efficiently computing the switching times of the control input and those times where the motor velocity changes sign. When imposing state constraints on the velocities, the optimal control becomes a rather complex combination of bang-bang and boundary arcs. The computed optimal controls were implemented on a real system and turned out to be in perfect agreement with measured test bench results.

IC/MP331/061: Modelling and design of complex systems.

Organiser: Michel Delfour (Université de Montréal, Canada)

The design of endoprotheses in biomechanics or complex mechanical structures such as tires for cars require careful mathematical and reliable numerical modelling from basic physical or biological principles that preserve the essential features without unduely increasing the size of the model in order to be able to successfully handle the numerical optimization/design stage. Examples will be given from interventional cardiology and the tire manufacturing industry.

Adaptive finite-element method for free-surface problems. **André Fortin** (Université Laval, Canada) IC/MT334/061

An adaptive finite element method for the simulation of various free surface problems will be presented. A level set method is used to compute the position of free surfaces. The mesh is adapted at each time step in order to concentrate the mesh at the interface. This allows to impose interface equilibrium conditions with very good accuracy. Various applications will be presented: drop to drop interaction in fluid flow problems, phase change in cryotherapy, die swell of viscoelastic fluids, etc.

Simulation of aerosols in the airway tract with a 3D Eulerian model. **Yves Bourgault** (Université d'Ottawa, Canada), Marc Thiriet (Université Paris VI, France) IC/MT1980/061

The numerical prediction of the propagation of aerosols in airways is an area of growing interest [1,2]. For instance, predicting the deposition patterns of particles in the mouth-throat or the inner lung pathways is needed for designing inhalers. Indeed recovering experimental deposition patterns, both in vivo and in vitro, happens to be difficult and expensive, and one often has to rely on numerical models of gas-particle flows for predicting such patterns in a cost-effective way. Two approaches are commonly used to model such multiphase flows, namely the Eulerian and Lagrangian approaches, but much of the literature on aerosols in airways rely on the Lagrangian tracking approach [1,2]. A common justification for the use of

the Lagrangian approach is that air flows in airways are internal and pulsatile, and present reverse flow regions, potentially leading to crossing particle trajectories. These arguments have been partly waived by a recent paper [3]. An Eulerian model could provide a competitive approach to compute internal dilute gas-particle flows, even in the presence of recirculations. In [4], we obtained numerical results of gas-particle flows in a 2-D prototype airway using a FEM for an Eulerian model.

In the current paper, we will extend our previous Eulerian model to the aerosol propagation in 3-D patient-based geometries of the airway tract. In [5], CT images of the thorax were processed to generate the geometry of the trachea and the first six bronchus generations. The air flow was then obtained by solving the Navier-Stokes equations for different values of the flow dimensionless parameters. In this paper, numerical results for aerosol propagation in these geometries are obtained by coupling our Eulerian model with the previous flow solutions. The results show that the particle density and deposition patterns are easily obtained at all time steps without any need for particle count or the delicate selection of initial particle positions, as for the Lagrangian tracking approach.

Time-dependent flow simulation in a carotid bifurcation. **Andre Garon** (École Polytechnique de Montréal, Canada) IC/MT354/061

We present the finite element flow simulation in a carotid bifurcation. This time-dependent simulation will be compare to 3D time-resolved PIV measurement for validation and accuracy evaluation. We will discuss the effect of newtonian versus non-newtonian model on the shear-stress at the bifurcation for different LVAD(left ventriculat assist device) support.

Modelling and design of stents in interventional cardiology. **Michel Delfour** (Université de Montréal, Canada) IC/MT332/061

Stents are used in interventional cardiology to keep a diseased vessel open. New stents are coated with a medicinal agent to prevent early reclosure due to the proliferation of smooth muscle cells. It is recognized that it is the dose of the agent that effectively controls the growth. This paper focusses on the asymptotic behavior of the dose for general families of coated stents under a fixed ratio between the coated area of the stent and the targeted area of the vessel and set therapeutic bounds on the dose. It generalizes the results of Delfour, Garon, and Longo (SIAM J. Appl Math) for stents made of a sequence of thin equally spaced rings to stents with an arbitrary pattern. It gives the equation of the asymptotic dose for a normal tiling of the target region.

IC/MP331/061: Modelling and design of complex systems. #2

Organiser: Michel Delfour (Université de Montréal, Canada)

(For abstract, see session #1 above.)

Fluid–kinetic models for sprays. **Laurent Boudin** (Université Paris VI, France) IC/MT4460/061

Fluid-kinetic models are often used when small particles or droplets evolve in an ambient fluid. That situation happens in medicine (therapeutic aerosols in the airways), but also in the military industry. Some examples within those frameworks will be investigated during the talk.

The standard fluid quantities, like mass density ϱ or velocity u, are solutions of the Euler or Navier-Stokes equations.

The spray of particles is described through a kinetic equation, typically, a fitted Vlasov equation

$$\partial_t f + v \cdot \nabla_x f + \nabla_v \cdot (f\gamma) + \partial_r (f\Phi) = 0,$$

where f denotes the particle probability density function, depending on time t, and on the location x, velocity v and characteristical size r of the particles. The acceleration γ holds information about the action of the fluid on the spray, and Φ describes the evolution of r.

The interaction between the two phases can be taken into account in mainly two ways. The first relevant question would be: can the action of the spray on the be neglected with respect to other phenomena? The second one: is the volume occupied by the spray neglictible with respect to the volume of the fluid?

We shall mainly present three different models which are used in the frameworks we already evoked, and eventually show some numerical results.

On the numerical simulation of the electro-cardiogram. **Miguel Fernández** (INRIA Rocquencourt, France), Muriel Boulakia (Université Pierre et Marie Curie, France), Jean-Frédéric Gerbeau (INRIA Rocquencourt, France), Najib Zemzemi (INRIA Rocquencourt, France) IC/MT4766/061

In this work we address the numerical simulation of electrocardiograms (ECG). We consider the bidomain equations to model the electrical activity of the heart and a Laplace equation for the torso. The ionic activity is modeled with the Mitchell-Schaeffer model. We use adaptive semi-implicit BDF schemes in time, finite elements in space, and a Neumann-Robin domain decomposition algorithm for the heart-torso coupling. The obtained ECGs, although not completely satisfactory, are promising. They allow to discuss various modelling assumptions, for example the relevance of cells heterogeneity, fiber orientation and the coupling conditions with the torso.

From reductionism to integrative modeling of living tissues. **Marc Thiriet** (Université Paris VI, France) IC/MT4768/061

Nowadays, most of the computational simulations related to physio/ pathophysiological problems are carried out in three-dimensional model of the subject anatomy obtained by 3D reconstruction from medical image acquisition. Imaging indeed yields the anatomy of the targeted organ, which more or less strongly varies between human subjects. However, these so-called subject-specific computational works deal with a frosen state of the explored organ. Biological tissues are living, and quickly adapt to environmental stimuli. In blood flows, the endothelium is subjected to both chemical cues from neighboring tissues or flowing blood and physical stresses applied by the blood. the endothelial cell changes its shape and gene expression in order to produce molecules which regulate flowing cell extravasation and aggregation, the vasomotor tone of adjoining smooth muscle cells, the substrate transport, and the composition of the extracellular matrix. Moreover, hypoxia, among other factors, leads to angiogenesis, a process in which endothelial cells are particularly implicated. Integrative model of behaviour of living cells subjected to mechanical loading and chemical signaling from themselves, their local environment, and the body regulation system.

A comparison of error estimators for the anisotropic mesh adaptation in 3D compressible flow simulations. **Yves Bourgault** (Université d'Ottawa, Canada), Frédéric Alauzet (INRIA Rocquencourt, France), Adrien Loseille (INRIA, France), Marco Picasso (École Polytechnique Fédérale de Lausanne, Switzerland) IC/MT1966/027

Anisotropic mesh adaptation has proved to be a powerful strategy to improve the quality and efficiency of finite element methods [1]. These anisotropic mesh adaptation techniques were initially based on a metric derived from a numerical approximation of the Hessian of the solutions with, in the background, the use of *a priori* error estimates [1]. More recently, anisotropic *a posteriori* error estimators were derived and used to drive anisotropic mesh adaptation (see [2] and references therein). Both error estimation techniques turned out to be effective, but as far as we know, comparisons of these two approaches have not yet been done in the literature, especially for complex 3D phenomena.

It is the purpose of the current paper to compare adapted meshes and solutions for 3D external flows around a supersonic aircraft, as obtained with different error estimators. We use, among others, the most recent *a priori* error estimators developed in [3] and the anisotropic *a posteriori* error estimators of [2]. Compressible flows are computed using the vertex-centred finite volume method presented in [4]. Comparison of the estimators are made on the basis of the quality of the solutions and computational requirements. The anisotropic adapted meshes are obtained in a solver/mesher loop with the *mmg3d* mesh adaptation software. That software implements the local mesh modification techniques presented in [1]. The goal of the project is to develop simulation capabilities for complex 3D external flows that run on simple workstations in a limited time and with limited memory.

IC/MP78/061: PDE-constrained optimization: numerical analysis and scientific computing.

Organiser: Roland Griesse (RICAM Linz, Austria)
Co-organiser: Arnd Rösch (RICAM Linz, Austria)

The optimization and control of processes described by partial differential equations plays a key role in understanding complex physical phenomena, the creation of new industrial products and materials, and the enhancement of production cycles. In addition, PDE-constrained optimization is gaining importance in biology, medicine and finance. The enormous advances in scientific computing as well as computing hardware allow to attack truly large-scale optimization problems today. In particular, the development of preconditioning and domain decomposition strategies, and the parallelization of optimization algorithms permit the solution of problems with up to billions of unknowns. Simultaneously, the numerical analysis of PDE-constrained optimization problems has made substantial progress. This concerns in particular the development of discretization and regularization techniques, error estimates and the convergence analysis of numerical methods. The goal of this minisymposium is to bring together leading experts and junior scientists from both areas, scientific computing and numerical analysis in PDE-constrained optimization. The speakers will give an overview of recent results in error and convergence analysis, computational techniques, and their application to areas such as crystal growth, hyperthermia cancer treatment and large-scale source inversion problems.

Uncertainty estimation for large-scale PDE-constrained inverse problems. **Omar Ghattas** (University of Texas at Austin, USA) IC/MT3545/061

We address the problem of estimating model uncertainty for large-scale inverse problems governed by PDEs. The approach is based on low rank estimates of the reduced Hessian, which exploit the compact character of the data misfit term of many ill-posed inverse problems. This low-dimensional representation of model uncertainty can be used to facilitate uncertainty propagation. Applications are given to data assimilation problems for contaminant tranport.

Numerical analysis and algorithms in control and state-constrained optimization with PDEs. **Michael Hinze** (Universität Hamburg, Germany) IC/MT3553/061

We propose a tailored discrete concept for optimization problems with nonlinear PDEs including control and state constraints. Its key idea consists in conserving as much as possible the structure of the infinite-dimensional KKT (Karush-Kuhn-Tucker) system on the discrete level, and to appropriately mimic the functional analytic relations of the KKT system through suitably chosen Ansätze for the variables involved. We provide numerical analysis, including convergence proofs and adapted numerical algorithms. As a class of model problems we consider optimization with (nonlinear) elliptic and parabolic pdes. This allows to validate and to compare our concepts against existing approaches for the class of elliptic and parabolic control problems.

Inexact Kleinman–Newton solvers for Riccati equations. **Ekkehard Sachs** (Universität Trier, Germany & Virginia Tech, USA) IC/MT3569/061

Many optimal control problems involving PDEs require in practice the computation of feedback laws for an optimal control. This is achieved through the solution of a Riccati equation which can be large scale, since the discretized problems are large scale and require special attention in their numerical solution. The Kleinman-Newton method is a classical way to solve a Riccati equation. We extend this method to an inexact version and allow the subproblems to be solved by an iterative solver like Smith's method. A prototype of this method shows a substantial reduction of the numerical effort.

Hierarchical space mapping in state constrained optimal control. **Arnd Rösch** (RICAM Linz, Austria), Michael Hintermüller (Universität Graz, Austria) IC/MT3612/061

The space mapping approach for the minimization of complex systems is extended to a hierarchical framework which allows to take various, hierarchical model simplifications into account. The general framework is then applied to Moreau-Yosida regularized state constrained optimal control of PDEs, where the model hierarchy is induced by the regularization parameter and the mesh-size of discretization. The resulting method is of multilevel type and uses an inexact trust region technique for globalization. The talks ends by a report on numerical results.

IC/MP78/061: PDE-constrained optimization: numerical analysis and scientific computing. #2

(For abstract, see session #1 above.)

Interior-point methods for semi-infinite problems with PDE constraints. **Martin Weiser** (Zuse-Institut Berlin, Germany) IC/MT1424/061

The talk will address interior point methods for semi-infinite programs arising from optimal control problems with state constraints and finitely many controls. It will be shown that locally self-concordant integrated barrier functions can be constructed in a neighborhood of a generic optimal solution. An important point is that the barrier function depends on the spatial dimension of the constraints. Finally, numerical examples will be given.

On saturation effects in the Neumann boundary control of elliptic optimal control. **Mariano Mateos** (Universidad de Oviedo, Spain), Arnd Rösch (RICAM Linz, Austria) IC/MT1648/061

A Neumann boundary control problem for a linear-quadratic elliptic optimal control problem in a polygonal domain is investigated. The main goal is to show an optimal approximation order for discretized problems after a postprocessing process. It turns out that two saturation processes occur: The regularity of the boundary data of the adjoint is limited if the largest angle of the polygon is at least $2\pi/3$. Moreover, piecewise linear finite elements cannot guarantee the optimal order, if the largest angle of the polygon is greater than $\pi/2$. We will derive error estimates of order h^σ with $\sigma \in [3/2, 2]$ depending on the lagest angle and properties of the finite elements. Finally, numerical test illustrates the theoretical results.

A regularization method for elliptic boundary-control problems with point-wise state constraints. **Fredi Tröltzsch** (TU Berlin, Germany), Irwin Yousept (TU Berlin, Germany) IC/MT3372/061

A Lavrentiev type regularization technique for solving elliptic boundary control problems with pointwise state constraints is considered. The main concept behind this regularization is to look for controls in the range of the adjoint control-to-state mapping. By the associated transformation, the problem becomes equivalent to a control-constrained one. After investigating the analysis of the method, a semismooth Newton technique based on the optimality conditions is presented. The theoretical results are confirmed by numerical tests. Moreover, they are validated by comparing the regularization technique with standard numerical codes based on the discretize-then-optimize concept.

Optimal control of temperature distribution in seeded sublimation growth processes of semiconductor single crystal. **Irwin Yousept** (TU Berlin, Germany), Christian Meyer (Weierstraß-Institut Berlin, Germany) IC/MT3441/061

The talk concerns the optimization of a class of nonlinear state-constrained control problems with nonlocal radiation interface conditions, which arise from crystal growth processes by the physical vapor transport (PVT) method. Mainly, due to the interface conditions and the presence of state constraints, the analysis of such problems is quite challenging. The main goal of the talk is to discuss the optimality conditions for the problem and based on them some numerical experiments are carried out.

IC/MP452/061: *Max-flow–min-cut* for continuous flows and related problems.

Organiser: Bernd Kawohl (Universität zu Köln, Germany)
Co-organiser: Gilbert Strang (Massachusetts Institute of Technology, USA)

A continuous maximum-flow problem finds the largest t such that $\operatorname{div} v = t\,F(x,y)$ has a solution in a plane domain Ω, satisfying a constraint $\|(v_1, v_2)\| \le c(x,y)$. The dual problem finds a cut ∂S of minimum capacity. At optimality, the minimum cut is filled to capacity by the maximum flow through S.
This model problem (a continuous version of the Ford-Fulkerson *max flow–min cut* theorem for flows on graphs) has recently found applications in medical imaging and in the modelling of landslides. It is connected with the construction of Cheeger sets, which minimize the ratio of perimeter divided by area among all subsets of Ω.

It is the purpose of the minisymposium to present recent results and open problems on *max flow–min cut* theorems and Cheeger sets.

Minimum cuts and maximum area. **Gilbert Strang** (Massachusetts Institute of Technology, USA) IC/MT488/061

The oldest competition for an optimal shape (area-maximizing) was won by the circle. We want to give the thousandth proof!

Then we measure the perimeter in different ways, which changes the problem (and has applications in medical imaging). If we use the line integral of $|dx| + |dy|$, a square would win. Or if the boundary integral of $\max(|dx|, |dy|)$ is given, a diamond has maximum area. When the perimeter = integral of $\|(dx, dy)\|$ around the boundary is given, the area inside is maximized by a ball in the dual norm.

The second part describes the **max flow-min cut theorem** for continuous flows. Usually it is for discrete flows on edges of graphs. The maximum flow out of a region equals the capacity of the minimum cut. This duality connects to the isoperimetric problems that produce minimum cuts. But the flows are hard to find and a prize is unclaimed.

Discrete approximations to continuum optimal flow. **Ross Lippert** (Massachussetts Inst. Tech., USA) IC/MT1615/061

Problems in partial differential equations with inequality constraints can be used to describe a continuum analog to various optimal flow/cut problems. While general concepts from convex optimization (like duality) carry over into continuum problems, the application of ideas and algorithms from linear programming and network flow problems is challenging. The capacity constraints are non-linear (but convex).

In this talk, I will present an investigation of a discretized version of the planar maximum flow problem which preserves the non-linear capacity constraints of the continuum problem. The resulting finite-dimensional problem can be cast as a second-order cone programming problem or a quadratically constrained program. Good numerical results can be obtained using commercial solvers. These results were in good agreement with the continuum theory of a "challenge" problem posed by Strang.

Cheeger's constant, the continuous max flow-min cut theorem and the Makai-Hayman-Osserman inequality. **Daniel Grieser** (Carl von Ossietzky Universität Oldenburg, Germany) IC/MT3484/061

For a domain in Euclidean space, or a Riemannian manifold with boundary, Cheeger's constant gives a lower bound for the first Dirichlet eigenvalue of the domain. The question arises how to find lower bounds for Cheeger's constant. A very simple, but not well-known idea is to use certain 'test vector fields' for this. The continuous version of the max flow min cut theorem then states that a vector field exists for which the estimate obtained in this way is sharp.

We will also show how a modification of this idea gives a new proof of the inequality of Makai (often attributed to Hayman or Osserman), which bounds the first eigenvalue of a plane, simply connected domain from below in terms of the inradius.

Explicit solutions of the equation $-\operatorname{div} z = f$ under side-constraint $\|z\| = 1$. **Zoja Milbers** (Universität zu Köln, Germany) IC/MT1693/061

We consider the variational problem:

$$E(u) := \int_\Omega d|Du| + \int_{\partial\Omega} \left| u^{\partial\Omega} \right| \mathrm{d}x \to \text{Min!}, \quad u \in BV(\Omega),$$

$$G(u) := \int_\Omega |u| \mathrm{d}x = 1\,.$$

The formal Euler-Lagrange equation to this nonsmooth problem would be

$$-\operatorname{Div}\left(\frac{Du}{|Du|}\right) = \lambda \frac{u}{|u|}\,.$$

However, it is known that a suitable multiple of the characteristic function χ_C of the Cheeger set C of Ω is a minimizer of the variational problem and the Euler-Lagrange equation is not well defined for $u = \chi_C$. A suitable substitute for the Euler-Lagrange equation is given by the substitute equation

$$-\operatorname{Div} z(x) = \lambda S(u(x)),$$

where S on the right hand side is any measurable selection of the set-valued sign function $\operatorname{Sgn}(u(x))$, $z \in L^\infty(\Omega, \mathbb{R}^n)$ with $\|z\|_{L^\infty(\Omega,\mathbb{R}^n)} \le 1$, and $\lambda = E(u)$. The purpose of the present work is the investigation of the vector field z associated with the minimizers of the variational problem. In my talk, after recalling the known results, I construct solutions z of the substitute equation for different measurable selections for the square and show that for each measurable selection S one can find infinitely many vector fields z satisfying the substitute equation on Ω.

On facet breaking for crystalline mean curvature flow in 3D. **Giovanni Bellettini** (Dipartimento di Matematica, Universita' di Roma To, Italy) IC/MT2278/061

We analyze some examples of facet breaking/bending of a polyhedral set evolving by crystalline mean curvature in three dimensions. This problem is strictly related to understand which facets of the crystal admit a vector field with constant divergence and satisfying suitable convex constraints. Work in collaboration with M. Novaga (Dipartimento di Matematica, Università di Pisa, Largo B. Pontecorvo 5, 56127 Pisa, Italy, E-mail: novaga@dm.unipi.it) and M. Paolini (Dipartimento di Matematica e Fisica, Università Cattolica di Brescia, via Trieste 41, 25121 Brescia, Italy E-mail: paolini@dmf.unicatt.it).

Convex calibrable sets in $\mathbb{R}^N$ and uniqueness of Cheeger sets inside convex bodies. **François Alter** (CMLA - ENS Cachan, France) IC/MT3630/061

The total variation approach to image denoising can be written as the minimization problem

$$\min_{u \in BV(\mathbb{R}^N) \cap L^2(\mathbb{R}^N)} \int_{\mathbb{R}^N} |Du| + \frac{1}{2\lambda} \int_{\mathbb{R}^N} (u - f)^2 \, dx, \qquad (1)$$

where $f \in L^2(\mathbb{R}^N)$ is the image to be denoised and $\lambda > 0$ is a regularization parameter. The search for explicit solutions of (1) leads to a series of interesting geometric problems related to the characterization of calibrable sets in $\mathbb{R}^N$. A convex body in $\mathbb{R}^N$ is calibrable if for any $\lambda > 0$ its denoising is written as a multiple of itself. Calibrable sets immediately give explicit solutions of (1). We provide a geometric characterization of convex $C^{1,1}$ calibrable sets in $\mathbb{R}^N$ in terms of the mean curvature of its boundary, extending Giusti's result in $\mathbb{R}^2$. We also prove the uniqueness of Cheeger sets inside a convex body in $\mathbb{R}^N$. This result permits to solve the capillary problem in

absence of gravity and vertical contact angle inside a convex Cheeger set, having a geometric characterization of those sets in terms of the mean curvature of its boundary.

Discrete and continuous parametric max-flow. **Antonin Chambolle** (École Polytechnique, France) IC/MT2303/061

The parametric max flow algorithm has been introduced by Gallo, Grigoriadis and Tarjan in order to solve quickly successive graph cuts problems with monotone capacities. It relies on a simple comparison principle for cuts in the same graph, with different outgoing capacities (from the source). We will describe in this talk the continuous version of this principle, and show if time permits how it can be applied for studying (both theoretically and numerically) the solutions of Total Variation minimization problems, with convex penalization. The main collaborator on this study is Jérôme Darbon (UCLA).

Cheeger sets and their construction. **Bernd Kawohl** (Universität zu Köln, Germany) IC/MT1389/061

Given a domain Ω, its Cheeger set is defined as the subset D of Ω, which minimizes perimeter over volume among all subsets. This geometric variational problem arises as a limit problem, as $p \to 1$, for eigenfunctions of the p-Laplace operator. In my lecture I will present examples of Cheeger sets and discuss their uniqueness and explicit construction. Part of this work was obtained jointly with Thomas Lachand-Robert.

IC/MP1015/061: Optimal control with PDEs on gas networks.

Organiser: Jens Lang (TU Darmstadt, Germany)
Co-organiser: Alexander Martin (TU Darmstadt, Germany)

This minisymposium is concerned with the solution of optimization and control problems for flow processes in gas networks. Gas flow problems on networks are described by a hierarchy of local dynamics (PDEs or ODEs) on the edges and transmission conditions at the nodes of the network. The overall dynamics is optimized by discrete decision variables and by continuous control variables according to a certain target functional. Global solutions of corresponding optimization and control problems are obtained by a hierarchy of combinatorical and continuous methods. The successful solution of such complex problems requests the combination of mathematical modelling, mixed-integer optimization, discrete and continuous control theory and numerical mathematics. New mathematical challenges as well as actual solution strategies will be discussed.

Multiscale models for simulation and optimization of gas networks. **Michael Herty** (TU Kaiserslautern, Germany), Axel Klar (TU Kaiserslautern, Germany) IC/MT1530/061

We are interested in gas flow in pipe networks. Several models for the dynamics inside the pipe are known which range from partial differential equations to purely algebraic relations. Usually, the dynamics of different pipes is coupled at pipe fittings and we discuss the mathematical and physical reasonable coupling conditions in particular for nodes which model compressors. We are interested in questions of well-posedness and existence of solutions near such nodes with respect to the different known models. We present numerical simulation and optimization results for compressor control based on the introduced model hierarchy.

Gas optimization by mixed integer-programming techniques. **Alexander Martin** (TU Darmstadt, Germany) IC/MT3118/061

We focus on the combinatorics in the gas optimization problem, that is on the questions which of the compressors to switch on or off and which of the valves to open or close in order to cost-efficiently satisfy all customer demands. We model these decisions as a mixed integer program (MIP) by approximating the inherent nonlinearities by piece-wise linear functions. We solve the resulting MIP by primal and dual methods including branch-and-cut and report on computational results for realistic networks.

Adaptive linearized models for optimization of gas networks. **Oliver Kolb** (TU Darmstadt, Germany), Jens Lang (TU Darmstadt, Germany) IC/MT2644/061

We are interested in simulation and optimization of gas networks. Usually, a gas network consists of different components like compressors and valves connected by pipes. The aim is to run the network cost efficiently whereas demands of consumers have to be satisfied. This results in a complex nonlinear mixed integer problem. We address this task with methods provided by discrete optimization. Therefore, the gas dynamics in all pipes must be described by piecewise linear constraints. We introduce an adaptive approach for the linearization process to handle the complexity on the one hand and the aimed accuracy on the other. We present numerical simulation and optimization results based on our model.

Optimal control of networks of gas pipelines. **Siarhei Dymkou** (Universität Erlangen–Nürnberg, Germany), Günter Leugering (Universität Erlangen–Nürnberg, Germany) IC/MT2230/061

We consider the optimization and control of gas-flow in networks of pipelines. The main objective is to maximize the throughput through the pipeline from the providers to the customers by choosing proper valve- and release-configurations as well as compressors in order to maintain the pressure in given bounds. This problem is considered in the context of bilevel optimization. In particular, after a discretation of the governing partial differential equations on the entire network, we obtain a discrete in space and time dynamical network-flow problem which is optimized with respect to compressor-data and valve-activities taking into account bounds on the discrete flow variables. On the second level, we consider, wherever the flow characteristics make it necessary, the continuous model (or a hierarchy of finer discretizations of it) to which, in turn, we apply continuous as well as switching controls.

IC/MP259/061: Multigrid/multilevel approaches to the optimization of systems governed by partial differential equations.

Organiser: Robert Lewis (College of William and Mary, USA)
Co-organiser: Stephen Nash (U.S. National Science Foundation)

This minisymposium examines multigrid/multilevel techniques in the optimization of systems governed by partial differential equations (PDE). The governing PDE introduces structure to the optimization problem hat can make the latter amenable to solution via multigrid/multilevel techniques. The situation is made more interesting by the fact that these types of optimization problems may involve discretized optimization decision variables, in addition to the discretized state variables representing the solution of the PDE. The talks in this minisymposium discuss the analytical and computational aspects of applying multigrid/multilevel techniques in the context of optimization.

One-shot multigrid method for aerodynamic shape optimization. **Subhendu Hazra** (Universität Trier, Germany) IC/MT1850/061

This talk presents a numerical method for aerodynamic shape optimization problems. It is based on simultaneous pseudo-time stepping in which stationary states are obtained by solving the pseudo-stationary system of equations representing the state, costate and design equations. The main advantages of this method are that it blends in nicely with previously existing pseudo-time stepping method for state and costate equations, that it requires no additional globalization in the design space, and that a preconditioner can be used for convergence acceleration which stems from the reduced SQP methods. To accelerate further the convergence of the method, 'optimization based' multigrid strategy is used. In this method, different optimization problems of similar structure are formulated at different discretization levels. Each of these optimization problems is solved using simultaneous pseudo-time stepping method. The coarse grid problems are computationally less expansive and helps in finding the optimal direction of the fine grid problems faster. For design examples of 2D problems, the overall cost of computation can be reduced to less than 2 times the forward simulation runs.

Multilevel algorithms for large-scale interior-point methods in bound constrained optimization. **Eldad Haber** (Emory University, USA) IC/MT4103/061

We develop and compare multilevel algorithms for solving bound constrained nonlinear variational problems via interior point methods. Several equivalent formulations of the linear systems arising at each iteration of the interior point method are compared from the point of view of conditioning and iterative solution. Furthermore, we show how a multilevel continuation strategy can be used to obtain good initial guesses (Şhot startsŤ) for each nonlinear iteration. A minimal surface problem is used to illustrate the various approaches.

Length-scale and spatial locality effects in the optimization of systems governed by differential equations. **Robert Lewis** (College of William and Mary, USA) IC/MT2447/061

We discuss locality and non-locality in frequency and space in the optimization of systems governed by differential equations. These analytical features have their origin in the abstract nature of the reduced Hessians that arise in the nonlinear programs describing such problems. These analytical features, in turn, have consequences for the development of multi-scale / multigrid schemes for the optimization of systems governed by differential equations. We present analytical and numerical results that suggest why, in many cases, we can be hopeful that multi-scale methods will be effective for such optimization problems. We also discuss why, in other situations, an element of domain decomposition is needed.

IC/MP1050/043: Preconditioned iterative methods for PDE constrained optimization.

Organiser: Marcus Sarkis (WPI/USA and IMPA/Brazil)
Co-organiser: Xiao-Chuan Cai (University of Colorado at Boulder, USA)

Among optimization problems with constraints, those constrained by nonlinear partial differential equations are very challenging, both mathematically and computationally. Examples of such problems are inverse, optimal design and optimal control problems. In inverse problems some parameters of the governing equations of the system behavior are not known and must be estimated by analysis of experimental system output data. Optimal design problems usually refer to problems where the variable is the shape of a domain and one has to find the best shape that minimizes or maximizes an objective function. In optimal control problems one usually searches for the best feasible control variables, such as boundary values or external forces that minimize or maximize a certain system behavior, such as turbulence. The focus of this minisymposium will be on the recent development of analysis and algorithms for the solution of large-scale systems arising from the discretizations of partial differential equations constrained optimization problems including domain decomposition methods, multilevel methods, and Krylov subspace methods, parallel performance. The aim of this minisymposium is to bring together scientists working in this field to report recent developments in the academic research, as well as in real life engineering applications.

On Schwarz-type smoothers for saddle-point problems with applications to PDE-constrained optimization problems. **Rene Simon** (Universität Linz, Austria), Walter Zulehner (Universität Linz, Austria) IC/MT2146/061

In this talk we consider additive (and multiplicative) Schwarz-type iteration methods for saddle point problems as smoothers in a multigrid method. Each iteration step requires the solution of several small local saddle point problems. In a previous work (by Joachim Schöberl and Walter Zulehner) the general construction of such patch smoothers for mixed problems were discussed. It was shown that, under suitable conditions, the additive Schwarz-type iteration fulfills the so-called smoothing property, an important part of a multigrid convergence proof, and the theory was applied to the Stokes problem. Here we consider a certain class of optimization problems from optimal control. A natural property of the corresponding Karush-Kuhn-Tucker (KKT) system, a 2-by-2 block system which characterizes the solution of the optimization problems, is the positivity of the (1,1) block only on the kernel of the (2,1) block. We extend the results for the Stokes problem to PDE-contrained optimization problems and present a patch smoother, which allows a rigorous convergence analysis of the corresponding multigrid method.

Computing bounds to exact outputs of PoissonŠs equation. **Marius Paraschivoiu** (Concordia University, Canada), Shahin Ghomeshi (Concordia University, Canada), Zhong Cheng (Concordia University, Canada) IC/MT2428/061

In this work we describe a method for obtaining rigorous upper and lower bounds to an output of the exact solution of the three-dimensional Poisson problem. The basic approach stems from the two-level residual based technique where the global problem is decomposed into independent local elemental subproblems by relaxing the continuity along the edges of a triangular partitioning of the entire domain, using approximate Lagrange multipliers. The method then exploits the Lagrangian saddle point property by recasting the output problem as a constrained minimization problem, and the constraints are the modified finite element equilibrium equations and the inter subdomain continuity requirements. An augmented Lagrangian is then constructed, which includes the output and the constraints as part of its formulation and the objective is then a quadratic error formulation of the desired output to be minimized. The gradient condition of the Lagrangian, then leads to four discrete problems: the primal-adjoint pair and two equilibration equations which yield the Lagrange multipliers due to the constraints. More recently, bounds to the exact outputs of interest have been obtained for the Poisson equation, the advection-diffusion-reaction equation, and the linear elasticity equation. However, the results presented were restricted to two-dimensions. The new ingredients in this work are two-fold: first, the finite element tearing and interconnecting (FETI) is invoked in order to calculate the inter-subdomain continuity multipliers (hybrid fluxes) and then extend the approach to three-space dimensions where we present bounds to the exact output of interest in a cube geometry. Secondly, the computational cost in computing the primal-adjoint pair of equations is addressed by using the FETI procedure in the calculations of the elemental subdomain solutions, which thus avoids the need for these global calculations.

Approximation of the Hessian for large-scale optimal-design problems. **Eyal Arian** (Boeing, Seattle, USA) IC/MT2588/061

In the area of aerodynamic design optimization second order derivatives are required to achieve accurate optimal solutions. These are not available in the current technology at Boeing (TRANAIR) since their computation requires unaffordable computing resources. Instead low rank quasi-Newton methods are used that build the Hessian using an update strategy which is not sufficient to achieve tight convergence given the available resources. Our interest is in developing a different method to approximate the Hessian that involves the exploitation of the structure imposed by the governing partial differential equations, and has the potential of improving the convergence of aerodynamic design optimization by orders of magnitude. In this talk a summary of the latest developments in this area will be presented.

IC/MP1050/043: Preconditioned iterative methods for PDE constrained optimization. #2

Fully-coupled domain-decomposition methods for inverse elliptic problems. **Xiao-Chuan Cai** (University of Colorado at Boulder, USA) IC/MT2526/061

In this talk we discuss a class of parallel full space Lagrange–Newton–Krylov–Schwarz (LNKSz) algorithms for inverse elliptic problems. In LNKSz, a Lagrangian functional is first formed according to the inverse elliptic problem with a proper regularization, and then differentiated to obtain an optimality system of nonlinear equations. Inexact Newton's method with line search is then applied directly to the fully coupled nonlinear optimality system and at each Newton's iteration the Jacobian system is solved with a Krylov subspace method preconditioned with an overlapping additive Schwarz method. We apply LNKSz to some parameter identification problems described as minimization problems constrained by elliptic partial differential equations. We report some promising results of a PETSc based parallel implementation of LNKSz for several different types of inverse problems. This is a joint work with S. Liu and J. Zou.

An optimal preconditioner for a class of distributed control PDE constrained optimization problems. **Sue Dollar** (Rutherford Appleton Laboratory, UK), Tyrone Rees (University of Oxford, UK), Andy Wathen (University of Oxford, UK) IC/MT1655/061

The nature of the quadratic sub-problems within PDE-constrained optimization problems means that iterative methods are frequently used to solve the resulting saddle-point systems of the form

$$\begin{bmatrix} A & B^T \\ B & 0 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} b \\ d \end{bmatrix}.$$

Constraint preconditioners have shown much promise in the context of using iterative methods for solving many of the saddle-point problems that arise from finite dimensional optimization problems. By considering a class of distributed control PDE constrained optimization problems, we will show that various constraint preconditioners can be used with these problems. Significantly, applying the preconditioning step within an interative method requires only solves with diagonal matrices *and* the preconditioners are optimal: typically only a few PPCG iterations are required for the various problems we have considered.

Reconstruction of 3D distributed parameter functions with discontinuities. **Uri Ascher** (University of British Columbia, Canada) IC/MT1614/061

We consider inverse problems of shape recovery from noisy boundary data, where the forward problem involves the inversion of elliptic PDEs. The piecewise constant solution, a scaling and translation of a characteristic function, is described in terms of a smoother level set function. We have recently proposed a fast and robust dynamic regularization method for this purpose.

For problems of moderate size in two spatial variables, direct linear algebra methods have been found rather effective. For larger problems, especially in three spatial variables, iterative methods are required. Perhaps contrary to initial intuition, the iterative methods are particularly useful for the inverse rather than the forward linear systems. Preconditioned CG is investigated and the efficacy of the obtained method is demonstrated.

Joint work with K. van den Doel

IC/MP3827/061: Optimization for systems governed by partial differential equations.

Organiser: Chunming Wang (University of Southern California, USA)
Co-organiser: Gary Rosen (University of Southern California, USA)
Co-organiser: Gunther Peichl (Universität Graz, Austria)

The mathematical theory and computational techniques for the optimization of systems governed by partial differential equations and other infinite dimensional systems have become increasingly relevant in a host of engineering and scientific applications including atmospheric and geophysical data assimilation, weather modeling and forecasting, flow control, nanophotonic and quantum electronic device design, and optimal design for advance materials manufacturing. In many of these application areas, development of mathematical approaches play a key role in the advancement of both the technology and the science. In addition to the numerical solution of the underlying partial differential equations and resulting nonlinear programming problems that are fundamental to these applications, there are also a significant number of other mathematical challenges that are common to optimal control, estimation and design problems. These challenges include dimensionality explosion for many estimation and design problems, nonconvexity of objective functions, computational challenges resulting from the need for efficient and highly accurate evaluation of derivatives, to name just a few. The field of optimal control, estimation and design for distributed parameter systems has seen great expansion in recent years with the growth of the readily availability of advanced and high performance computational resources. This has resulted in significant and important technological advances in many application areas. The synergistic relationship between distinct and diverse applications has the potential to lead to breakthroughs in many more areas of scientific research and engineering development. The speakers in this session represent a large cross-section of the community of mathematicians working in this important area of applied mathematics. Their presentations showcase their successes in developing, using, and analyzing wide ranging mathematical theory and computational methods to solve control, estimation and design problems in the context of a variety of applications involving partial differential equations at the frontier of scientific and engineering research.

Shape-optimization/fictitious-domain approach for numerical realization of a class of free-boundary problems. **Jaroslav Haslinger** (Univerzita Karlova, Czech Republic) IC/MT3808/061

A moving-boundary problem with kinetic condition: well-posedness of weak solutions and parameter identification issues. **Adrian Muntean** (Universität Bremen, Germany) IC/MT3876/061

We report on new results concerning global existence, uniqueness and stability with respect to data and parameters of weak solutions to a two-phase non-equilibrium moving-boundary system arising in the carbonation of concrete. The main feature of the model is the use of a kinetic condition for driving the interface into the unsaturated reactive porous material. Few issues concerning the identification of some diffusion rates as well as the identification of the moving boundary are also addressed.

Variational approach to shape derivatives. **Gunther Peichl** (Universität Graz, Austria) IC/MT1186/061

A general framework for calculating shape derivatives for optimization problems with partial differential equations as constraints is presented. The proposed technique allows to obtain the shape derivative of the cost without the necessity to involve the shape derivative of the state variable. In fact, the state variable is only required to be Lipschitz continuous with respect to the geometry perturbations. Applications to inverse interface problems, and shape optimization for elliptic systems are given.

A level-set method for a shape optimization problem in induction heating processes. **Rachid Touzani** (Université Clermont-Ferrand, France), Anis Kooli (Universite Blaise Pascal, Clermont-Ferrand, France) IC/MT1823/061

We consider, in this presentation, a coupled elliptic–parabolic problem involved in electromagnetic induction processes. In order to design efficient inducting devices, we formulate a topological shape optimization problem. The problem is solved by using a level set formulation. Using the material derivative technique, we derive the gradient expression of the objective function and formulate a level set equation. Numerical simulations demonstrate the efficiency of the numerical method.

Design and optimization of quantum systems. **Russel Caflisch** (University of California, Los Angeles, USA) IC/MT2071/061

This talk will describe the simulation, design and optimization of quantum systems. The examples are a qubit for use in quantum communication or quantum computation and a layered device designed to give a desired electron transmission probability. In the first example, the qubit is realized as the spin of a single trapped electron in a semi-conductor quantum dot. The quantum dot and a quantum wire are formed by the combination of quantum wells and gates. The design goal for this system is a "double pinchoff", in which there is a single trapped electron in the dot and a single (or small number of) conduction states in the wire. Because of considerable experimental uncertainty in the system parameters, the optimal design should be "robust", in the sense that it is far away from unsuccessful designs. We use a Poisson-Schrödinger model for the electrostatic potential and electron wave function and a semi-analytic solution of this model. Through a Monte Carlo search, aided by an analysis of singular points on the design boundary, we find successful designs and optimize them to achieve maximal robustness. In the second example, the stoichiometry of the layers are chosen to best match the desired transmission probability. These values are optimized using a multiscale random search, in which a coarse grained model is used to find the basins of attraction, and a find scale model is used to get to the bottom of the basins.

Mathematical approach for optimal design of electromagnetic and photonic devices. **Chunming Wang** (University of Southern California, USA), Anthony Levi (University of Southern California, USA), Philip Seliger (University of Southern California, USA) IC/MT516/061

Optimal design of photonic devices is a crucial step in the application of nano-technology. In these design problems the number of design parameters is often very large. The multitude of phyiscal constrains severely limit the designers' ability to use their intuition to obtain optimal designs. Mathematical system theory and optimization technique offer considerable promise for assisting designers of these devices. In this presentation, we discuss the objective and formulation of a design problem of electro-magnetic wave-guide using dielectric scattering materials. This design problem is used as a prototype design problem for photonic device design because the physics of this problem can be scaled to photonic device size. An adjoint method based optimization technique is used for the search of locally optimal designs. The modeling and the design approach is validated by carefully constructed laboratory experiments. The significant agreement between optimal design derived by the design software and the experimental results demonstrates the power of the optimal design approach. We shall also present in this talk our attempts in addressing sensitivity and robustness of the optimal designs.

IC/MP146/061: Optimal control, estimation, and design for systems governed by partial differential equations: theory and computational methods. #2

Organiser: Chunming Wang (University of Southern California, USA)
Co-organiser: Gunther Peichl (Universität Graz, Austria)
Co-organiser: Gary Rosen (University of Southern California, USA)

(For abstract, see session #1 above.)

Generalized sensitivity analysis in a delay system. **Franz Kappel** (Universität Graz, Austria) IC/MT995/061

In contrast to classical sensitivity which describes the dependence of a model output on parameters, generalized sensitivity is a measure for the sensitivity of estimated parameters against measurements. In the talk we generalize this concept for delay systems.

Two-scale models for corrosion of porous media . **Sebastian Meier** (Universität Bremen, Germany), Michael Böhm (Universität Bremen, Germany) IC/MT1006/061

Reactive transport in porous media is governed by at least two highly different spatial scales: the *pore scale* and the *macroscopic scale*, the latter of which is usually of interest in applications. For special classes of problems it has been shown by periodic homogenisation that two-scale models are appropriate, in which local transport and reaction as well as their influence on the evolving pore structure are described by local cell problems. A highly important industrial application is the chemical degradation of concrete structures via carbonation. Compared to classical averaged models, such two-scale models involve additional parameters describing the pore geometry (and its evolution!) that have to be identified.

We consider in detail the forward modelling problem leading to a system of parabolic PDEs and ODEs. Moreover, we indicate some relevant parameter identification problems. Due to the non-standard coupling of the equations, the setup of these problems seems to be rather intricate.

Deconvolving blood-alcohol concentration and alcoholic beverage consumption from biosensor measurements of transdermal alcohol. **Gary Rosen** (University of Southern California, USA), Miguel Dumett (University of Southern California, USA), Yuliya Piterbarg (University of Southern California, USA), Alan Schumitzky (University of Southern California, USA) IC/MT985/061

We consider the problem of determining blood alcohol concentration (BAC) and/or the quantity of alcohol consumed (CA) by a subject from biosensor observations of the amount of alcohol excreted through the skin via perspiration. Our approach involves the forward modeling of the transport of ethanol from ingestion, into the blood, through the skin and to the electrochemical sensor where it is processed and its quantity is recoded. The model consists of a system of coupled ordinary and partial differential equations. Once the physiological parameters in the model have been estimated, determining BAC and CA may be formulated as deconvolution problems where the underlying convolution kernel is the impulse response function for an infinite dimensional system. In this talk we will present and discuss our results for estimating the kernels, and the BAC and CA signals from actual patient data. In particular, we will discuss schemes that have allowed us to estimate the kernels deterministically with minimal patient data and statistically for entire populations of subjects. We will also discuss a method for deconvolving the CA signal in the form of an impulse train via a technique based on trigonometric moments that has been used in the sequencing of DNA.

Numerical solution of the free boundary Bernoulli problem. **François Bouchon** (Université Clermont-Ferrand, France), Stéphane Clain (Université Paul Sabatier Toulouse III, France), Rachid Touzani (Université Clermont-Ferrand, France) IC/MT1087/061

We present an iterative method to solve the Bernoulli problem. The scheme uses a perturbation technique to build a sequence of boundaries which converges to the solution of the problem. The boundaries are described by level set functions, which need to be calculated on the whole computational domain. The velocity of the interface is evaluated on the free boundary by solving an elliptic problem, using an immersed interface technic. A Fast marching method is then used both to extend the velocity on the computational domain, and to reinitialize the level set as the signed distance function. Numerical tests are presented to show the efficiency of the method.

IC/MP305/062: Stabilization and control for PDEs of interest to the applied sciences.

Organiser: Piermarco Cannarsa (Università degli Studi di Roma Tor Vergata, Italy)
Co-organiser: Fatiha Alabau Boussouira (Universite Paul Verlaine Metz, France)
Co-organiser: Judith Vancostenoble (Universite Toulouse III, France)

Partial Differential Equations (in short, PDEs) are widely acknowledged as an essential tool to study a large variety of applied systems, from physics to engineering, from biology to economics. Human actions on these systems, to drive them to a desired state or minimize a cost or a time of realization for a given state is an essential aim for engineering applications. This leads to the study of the so-called stabilization and control problems for PDEs.

On the one hand, one may want to use a controller to steer a given system to a prescribed configuration in finite time, or at least get close to it (exact and approximate controllability, respectively), or else converge asymptotically to a given configuration as $t \to \infty$ (stabilization). On the other hand, one may be interested in using controllers to optimize a given performance criterion or cost functional (optimal control). Both kind of problems are also important for equations including nonlocal terms, as this allows to model memory terms of interest to material science, in particular viscoelastic materials.

Stabilization and control problems for PDEs have been intensively studied over the last few decades under the pressure of such a rapidly increasing range of applications. New important ideas and techniques have been developed during the last five years or so to attack problems that had been reckoned as almost impossible to treat, such as Navier–Stokes equations, fluid–structure interaction, degenerate problems. Moreover, some of the techniques developed for a specific purpose turned out to be useful in completely different kinds of context, such as Carleman estimates that are relevant for controllability as well as inverse problems.

This minisymposium aims at illustrating some of the latest and most important achievements of the research in the above area, comparing different approaches and trying to single out possible new connections among them. Special focus will be devoted to PDE models that are relevant to material sciences, population genetics, fluid dynamics and aerodynamic shape optimization. Some presentations will be mainly concerned with the qualitative analysis of the model, others will rather dicuss numerical results.

Some controllability problems of evolution equations. **Oleg Emanouilov** (Colorado State University, USA) IC/MT2561/062

We discuss some recent results in the global exact boundary controllability of evolution equations such as the Navier–Stokes system, the Korteweg–de Vries equation, the cubic Shrödinger equation.

Observability time and semi-discretization. **Paola Loreti** (Universita' degli Studi di Roma "La Sapienza", Italy) IC/MT1208/062

The harmonic analysis method is a good tool to get rather precise estimates of the observability time for linear evolutionary partial differential equations. Our approach is based on a classical theorem due to Ingham [1].

In our talk first we recall well-known results in the continuous case. Then we present some recent theorems on semi-discretization. The new results we discuss were obtained in collaboration with V. Komornik[3] and M. Mehrenberger[5].

Carleman estimates for degenerate parabolic equations. **Patrick Martinez** (Universite Paul Sabatier Toulouse III, France), Piermarco Cannarsa (Università degli Studi di Roma Tor Vergata, Italy), Judith Vancostenoble (Universite Toulouse III, France) IC/MT2507/062

We study the controllability properties of parabolic equations degenerating at the boundary of the space domain.

We derive new Carleman estimates for the degenerate parabolic equation

$$w_t + (a(x)w_x)_x = f, \quad (t,x) \in (0,T) \times (0,1),$$

where the function a mainly satisfies

$$a \in C^0([0,1]) \cap C^1((0,1)),\ a > 0 \text{ on } (0,1) \text{ and } \frac{1}{\sqrt{a}} \in L^1(0,1).$$

We are mainly interested in the situation of a degenerate equation at the boundary i.e. in the case where $a(0) = 0$ and/or $a(1) = 0$. A typical example is $a(x) = x^\alpha(1-x)^\beta$ with $\alpha, \beta \in [0,2)$.

As a consequence, we deduce null controllability results for the degenerate one dimensional heat equation

$$u_t - (a(x)u_x)_x = h\chi_\omega, \quad (t,x) \in (0,T)\times(0,1), \quad \omega \subset\subset (0,1).$$

IC/MP305/062: Stabilization and control for PDEs of interest to the applied sciences. #2

Organiser: Piermarco Cannarsa (Università degli Studi di Roma Tor Vergata, Italy)

(For abstract, see session #1 above.)

Stabilization of the 2D Navier–Stokes equations by finite-dimensional controllers. **Jean-Pierre Raymond** (Université Paul Sabatier Toulouse III, France) IC/MT1887/062

We are interested in the boundary feedback stabilization of the incompressible Navier–Stokes equations, by a finite dimensional feedback controller, about an unstable stationary solution. Such stabilization problems have been recently studied with controls belonging to infinite dimensional spaces. Here we shall present two local stabilization results. In the first one, the feedback control is obtained by solving a control problem for an infinite dimensional system (even if the control is of finite dimension). In the second one, the feedback control is obtained by solving a control problem of finite dimension.

Remarks on the control of Euler and Navier–Stokes equations with applications to optimal shape design in aeronautics. **Francisco Palacios** (Instituto Nacional de Técnica Aeroespacial, Spain), Enrique Zuazua (Universidad Autónoma de Madrid, Spain), Carlos Castro (Universidad Politécnica de Madrid, Spain), Carlos Lozano (Instituto Nacional de Técnica Aeroespacial, Spain) IC/MT2031/062

In the present work we will address several issues concerning adjoint-based shape optimization problems in aeronautics. The key issue here is to obtain the sensitivity or gradient of a certain cost function under shape deformations. Adjoint techniques allow to dramatically reduce the computational cost of the procedure. Our aim, apart from swiftly reviewing the continuous adjoint methodology for the calculation of shape sensitivities, is to shed light on the discrete vs. continuous adjoint dichotomy, placing the emphasis on the well-posedness of the approaches, distinguishing between two independent issues which are normally mixed up in the literature: non-differentiability of numerical schemes and non-regular field solutions.

In practical design applications one works with numerical approximation of the flow equations, so the discrete adjoint method appears to be the natural approach. However, efficient numeric schemes are often non-differentiable and, consequently, the cost function depends on the solution and on the design parameters in a non-differentiable way. In a strict sense, it is therefore impossible to build gradient-based descent algorithms upon such schemes. To make things work in practice several tricks are used whose validity has to be carefully assessed. On the other hand, the continuous adjoint approach constitutes an alternative that allows to maintain the rigor throughout the whole procedure. However, in continuous schemes flow discontinuities may arise. In this case, shocks must be treated as singularities on which adjoint Rankine-Hugoniot conditions must be enforced.

We end by commenting on the application of the Level Set method to aeronautical design. The Level Set method is a numerical technique for tracking interfaces and shapes which, when suitably interpreted in the aeronautical design context, provides great versatility when working in cases where great changes in shape topology are either expected or desirable.

Stabilization for visco-elastic materials: abstract results and applications. **Fatiha Alabau Boussouira** (Universite Paul Verlaine Metz, France) IC/MT2469/062

We study visco-elastic materials for which the feedback law is of memory type, that is the feedback appears as a convolution operator with respect to time. We prove stabilization properties such as exponential or polynomial decay for general abstract hyperbolic equations with applications to various models.

About the vibration of a beam between two stops. **Jaime Muñoz Rivera** (Laboratório Nacional de Computação Científica, Brazil) IC/MT2041/062

We consider the vibration model of a thermoelastic beam with two transversal obstacles. The corresponding mathematical model is a variational inequality of fourth order. We show that there exist at least one solution which decay exponentially to zero. We also show that the solution of the variational inequality has smoothing effect property over the initial data. The uniqueness is an open question.

IC/MP321/062: Control of deterministic systems under state constraints.

Organiser: Hélène Frankowska (École Polytechnique, France)
Co-organiser: Piermarco Cannarsa (Università degli Studi di Roma Tor Vergata, Italy)

Constrained systems arise in different models of applied sciences (drug administration, robotics, aeronautics, chemistry, environmental sciences and many others). In recent years substantial progress was done in control theory for deterministic systems under general state constraints. In the past, a typical way to handle constraints was based on penalisation methods, which may be heavy to handle numerically and are usually less informative. Recently, direct methods were developed which helped to prove simultaneously necessary optimality conditions, their nondegeneracy and normality, and also to investigate the non occurrence of the Lavrentieff phenomenon for such models. This also allowed to develop the theory of second order optimality conditions, and obtain perimeter and volume estimates for the reachable set of state-constrained controlled system. Another important progress was done in sensitivity analysis and the extensions of Hamilton–Jacobi theory to constrained deterministic systems. The aim of this minisymposium is to give an overview of these recent advances and new methods.

Second-order conditions in stability analysis for state-constrained optimal-control problems. **Kazimierz Malanowski** (Polish Academy of Sciences, Poland) IC/MT1295/062

In stability analysis for optimization problems conditions are investigated, under which the solutions and Lagrange multipliers are locally Lipschitz continuous with respect to parameters. The methodolgy, based on Robinson's implicit function theorem for generalized equations, allows to reduce the stability analysis for nonlinear cone constrained optimization problems, to such an analysis for linear-quadratic accessory problems. Applying this methodology to nonlinear optimal control problems, we have to analyse stability of the solutions to linear-quadratic accessory optimal control problems, with respect to additive perturbations. In getting stability results for this class of problems, two types of assumptions are crucial: constraint qualifications and coercivity conditions. These conditions should be stable in a neighborhood of the reference point.

Clearly, we would like to have the assumptions as weak as possible. For control-constrained problems, a full characterization of the stability property is known. The situation is different for

state-constrained problems, where a strong coercivity condition has been used. The reason was the difficulty with proving stability of the weakened coercivity condition.

In the present talk, it will be shown that the second order conditions, weakened by taking into account the strongly active state constraints, are stable under small perturbations. The proof of this stability property, takes advantage of a mechanism, different from that used in the case of control constraints. The above result allows to obtain stability results for state-constrained optimal control problems, under assumptions weaker than those known from the literature.

On necessary conditions for state-constrained problems. **Maria Margarida Ferreira** (Universidade do Porto, Portugal), Maria do Rosário de Pinho (Universidade do Porto, Portugal) IC/MT2479/062

This work focuses on necessary conditions for weak local minimizers of optimal control problems with state constraints. More precisely the addressed problem is to minimize:

$$g(x(0),x(1)) + \int_0^1 L(t,x(t),u(t))\mathrm{d}t$$

subject to $\dot{x}(t) = f(t,x(t),u(t))$ and $h(t,x(t)) \leq 0$, with $u(t) \in U(t)$ and $(x(0),x(1)) \in C$.

For a weak local minimizer $(\bar{x},\bar{u})$ the non smooth maximum principle asserts, among other conditions, that

$$-\dot{p}(t) \in \operatorname{co} \partial_x H(t,\bar{x}(t),\bar{u}(t),q(t),\lambda) \quad \text{a.e.}$$
$$\max_{u\in U(t)} H(t,\bar{x}(t),u,q(t),\lambda) = H(t,\bar{x}(t),\bar{u}(t),q(t),\lambda) \quad \text{a.e.}$$

where p is an absolutely continuous function, q is a function of bounded variation, $\lambda \geq 0$ is a scalar and H is the Hamiltonian:

$$H(t,x,u,p,\lambda) = p \cdot f(t,x,u) - \lambda L(t,x,u)\,.$$

We derive in this work a nonequivalent necessary condition:

$$(-\dot{p}(t),\xi(t)) \in \operatorname{co} \partial_{x,u} H(t,\bar{x}(t),q(t),\bar{u}(t))\,, \quad \xi(t) \in \operatorname{co} N_{U(t)}(\bar{u}(t)) \quad \text{a.e.}$$

Non-degenerate necessary conditions for nonlinear optimal-control problems with higher-index state constraints. **Fernando Fontes** (Universidade do Minho, Portugal), Sofia Lopes (Universidade do Minho, Portugal) IC/MT3123/062

For some optimal control problems with pathwise state constraints the standard versions of the necessary conditions of optimality are unable to provide useful information to select minimizers. There exist some literature on stronger forms of the maximum principle, the so-called nondegenerate necessary conditions, that can be informative for those problems. These conditions can be applied when certain constraint qualifications are satisfied. However, when the state constraints have higher index (i.e. their first derivative with respect to time does not depend on the control) these nondegenerate necessary conditions cannot be used. This happens because constraint qualifications assumptions are never satisfied for higher index state constraints.

We note that control problems with higher index state constraints arise frequently in practice. An example is a common mechanical systems for which there is a constraint on the position (an obstacle in the path, for example) and the control acts as a second derivative of the position (a force or acceleration) which is a typical case.

Here, we provide a nondegenerate form of the necessary conditions that can be applied to nonlinear problems with higher index state constraints. When addressing a problem with a state constraint of index k, the result described is applicable under a constraint qualification that involves the k-th derivative of the state constraint, corresponding to the first time when derivative depends explicitly on the control.

Holder continuity of adjoint states and optimal controls for state constrained problems. **Hélène Frankowska** (École Polytechnique, France), Piernicola Bettiol (SISSA, Trieste, Italy) IC/MT1400/062

This talk is devoted to Hölder regularity of adjoint states and optimal controls for the Bolza optimal control problem under state constraints, where the goal is to minimize the functional

$$J(x,u) := \varphi(x(0),x(1)) + \int_0^1 \ell(t,x(t),u(t))\,dt$$

over all absolutely continuous $x(\cdot)$ and measurable $u(\cdot)$ satisfying

$$x'(t) = f(t,x(t),u(t)),\ u(t) \in U(t),\ x(t) \in K\ \forall\ t \in [0,1],\ (x(0),x(1)) \in K,$$

The associated Hamiltonian is defined by

$$H(t,x,p) = \sup_{u\in U(t)} \{\langle p, f(t,x,u)\rangle - \ell(t,x,u)\}.$$

Consider any optimal solution satisfying the normal constrained maximum principle and let $N_K(x)$ denote the normal cone to K at x. We show that whenever H is smooth and monotone in the directions normal to constraints, in the sense that for some $k > 0$ and $\beta \geq 1$

$$\begin{cases} \forall\ (t,x) \in [0,1]\times K \ \text{ and } \ \forall\ p,q \in R^n \ \text{ with } \ p-q \in N_K(x) \\ \left\langle \frac{\partial H}{\partial p}(t,x,p) - \frac{\partial H}{\partial p}(t,x,q), p-q \right\rangle \geq k|p-q|^{1+\beta}, \end{cases}$$

then both the adjoint state of the maximum principle and the derivative of this optimal trajectory are Hölder continuous for smooth constraints, while they are both side lower Hölder continuous for less regular constraints. Finally, we provide sufficient conditions for Hölder type regularity of optimal controls.

IC/MP321/062: Control of deterministic systems under state constraints. #2

Organiser: Hélène Frankowska (École Polytechnique, France)
Co-organiser: Piermarco Cannarsa (Università degli Studi di Roma Tor Vergata, Italy)

(For abstract, see session #1 above.)

Regularity of reachable sets under state constraints. **Pierre Cardaliaguet** (Université Brest, France) IC/MT1462/062

Recently the regularity problem of reachable sets for controls systems has attracted a lot of attention: in particular bounds on the size of the boundary has been used to investigate existence and uniqueness of solutions for some models of dislocation dynamics. Similar questions for control systems under state constraints turn out to be much more delicate. In this joint work with C. Marchi, we explain how to handle the problem in dimension 2.

An HJB approach for a deterministic state-constraint optimal-control problem without controllability assumption. **Olivier Bokanowski** (Université Pierre et Marie Curie, France) IC/MT3188/062

We study the optimal (deterministic) control problem with state constraints, without any particular controllability assumption. We are interested by the characterization of the value function as the lower semi-continuous viscosity solution of some Hamilton-Jacobi-Bellman equation.

Several results have been obtained in this direction, leading to the existence and uniqueness in the form of a PDE. In general either an inward constraint qualification (such as Soner's qualification's constraint [1]), or an outward constraint qualification (such as in Frankowska and Vinter [2]) is assumed. On the other hand, a characterization without qualification constraint is also obtained in Ref. [3], using a Viability approach.

In our approach, we give a PDE-like characterization. We use the concept of contingent epiderivatives as in [2], and also a new type of condition on the border of the constraint set. Known results using inward or outward qualification constraints can then be interpreted in this framework.

Motivated by the preliminary numerical work [4], we shall also propose a numerical procedure based on our theoretical results.

This is a joint work with N. Megdich and H. Zidani (UMA, Ensta, France).

Lipschitz continuity of solutions to Bolza optimal-control problems. **Elsa Maria Marchini** (Università degli studi di Milano-Bicocca, Italy) IC/MT2734/062

We investigate Lipschitz continuity of optimal solutions for the Bolza optimal control problem which consists in minimizing the functional

$$\int_0^T L(t,x(t),u(t))dt + g(x(0),x(T))$$

over all trajectory/control pairs (x,u) subject to the state equation

$$\begin{cases} x'(t) = f(t,x(t),u(t)) & \text{for a.e. } t \in I \\ u(t) \in U(t) & \text{for a.e. } t \in I \\ x(t) \in K & \text{for every } t \in I \\ (x(0),x(T)) \in Q, \end{cases}$$

with suitable assumptions on data. Since our result on regularity is a consequence of normal necessary conditions for optimality, we propose new sufficient conditions for normality of state-constrained non smooth maximum principles for absolutely continuous optimal trajectories.

Existence and regularity of solutions to Bolza problems with slow growth. **Piermarco Cannarsa** (Università degli Studi di Roma Tor Vergata, Italy) IC/MT2169/062

The existence and Lipschitz continuity of optimal trajectories for the Bolza problem is a classical topic in control theory. To study such a problem, the Lagrangian is usually assumed to possess superlinear growth at infinity in the control variables. In this paper, building on a work by Clarke for the calculus of variations, we provide sufficient conditions in Hamiltonian form for the existence and regularity of solutions to nonlinear optimal control problems with state constraints, relaxing the fast growth condition for the Lagrangian.

IC/MP244/063: Interior-point methods for model predictive control.

Organiser: Moritz Diehl (Katholieke Universiteit Leuven, Belgium)
Co-organiser: Steve Wright (University of Wisconsin, USA)

Model predictive control (MPC) is an advanced feedback control technique that requires the reliable solution of a sequence of optimization problems in real-time. One of the major reasons for its success in practice is its ability to deal with inequality constraints on controls and internal system states, which cannot be treated by most other existing feedback control techniques. The availability of reliable quadratic programming solvers based on active set strategies was a crucial factor in making the success of MPC since the 1980s possible, and active set methods are still used in many MPC applications.

On the other hand, tremendous progress has been made in the last decade in the optimization community in developing interior point methods for problems with large numbers of inequality constraints. Thus, when MPC optimization problems with several thousand inequality constraints shall be solved, interior point methods are often superior to active set methods. However, one of the main drawbacks of interior point methods for MPC can be seen in their limited warm starting capabilities, which are important in MPC, where a sequence of only slowly changing optimization problems are solved. This drawback limits the application of interior point methods in particular to fast MPC applications.

Aim of the minisymposium is to bring together two groups of people: on the one hand, control engineers that have successfully developed or used interior point methods for MPC optimization, and on the other hand numerical optimizers that are distinguished by their work on warm starting capabilities for interior point methods. The possible results of the minisymposium are unexpected contacts of people and ideas that shall help to advance the development of faster, practically applicable interior point methods for model predictive control.

Interior-point methods in MPC: a survey. **Steve Wright** (University of Wisconsin, USA), Moritz Diehl (Katholieke Universiteit Leuven, Belgium) IC/MT3393/063

We introduce this minisymposium by surveying the use of interior-point methods in model predictive control (MPC) to date. We discuss both linear and nonlinear MPC, and discuss the pros and cons relative to alternative approaches. We also discuss warm starting issues in interior-point methods, which are particularly relevant to MPC, as well as recently proposed applications to robust control.

Unblocking heuristics for warm-starting interior-point methods. **Andreas Grothey** (University of Edinburgh, UK) IC/MT2399/063

Warmstarting Interior Point Methods is difficult. Unlike the situation in the simplex method, an Interior Point warmstart might not be any better than a coldstart and can even lead to worse performance. A common observation with "failed" warmstarts are blocking directions: after a warmstart only very small steps can be made. We will address the question of how to find a good warmstarting point. Further we will present experience with a set of new heuristics targeted at directly unblocking the current step, resulting in better and more reliable warmstarts. We will present results on the Netlib test set as well as on a selection of large scale nonlinear problems.

A path-following method for parametric nonlinear complementarity problems. **Martin Weiser** (Zuse-Institut Berlin, Germany), Roland Griesse (RICAM Linz, Austria), Moritz Diehl (Katholieke Universiteit Leuven, Belgium) IC/MT1586/063

The talk presents an algorithmic framework based on regularized complementarity functions for approximately solving parametric nonlinear complementarity problems as they arise in particular in nonlinear model predictive control. The aim is to select step sizes and regularization such that an inexact pathfollowing scheme limited to one Newton correction per step is able to reliably follow the parameter-dependent solution. Features of the approach are discussed on the basis of several numerical examples.

A continuation/GMRES method for real-time algorithm of constrained nonlinear-model predictive control. **Toshiyuki Ohtsuka** (Osaka University, Japan), Yuichi Shimizu (Osaka University, Japan), Moritz Diehl (Katholieke Universiteit Leuven, Belgium) IC/MT1825/063

This talk gives an overview of a continuation-based real-time algorithm for nonlinear model predictive control. The optimal solution is updated by solving a linear equation only once at each sampling time, and the linear equation can be solved efficiently with a Krylov subspace method, GMRES. In addition to the basic idea of the algorithm, implementation examples for mechanical systems are presented with emphasis on practical handling of inequality constraints. These are treated by the introduction of penalized slack variables in a way that bears some similarity to interior point methods with a fixed barrier parameter.

A sensitivity-based barrier strategy for nonlinear-model predictive control. **Lorenz Biegler** (Carnegie Mellon University, USA), Victor Zavala (Carnegie Mellon University, USA) IC/MT2497/063

In less than two decades, Nonlinear Model Predictive Control (NMPC) has evolved from a conceptual framework to a tractable and well-demonstrated approach for the control of constrained nonlinear processes. These advances have been realized both through better understanding of stablity and robustness properties, as well as improved nonlinear programming (NLP) formulations and algorithms for dynamic optimization. This talk further reduces the on-line computational expense for NMPC through the development of a sensitivity-based formulation consisting of the following steps:

- A large, sparse NLP is formulated through a total discretization of the moving horizon problem.
- The discretized NMPC problem is solved in background using a fast barrier NLP method.
- As new state information is received, the NLP solution is immediately updated on-line using a sensitivity-based formulation derived from the barrier method.

Our initial tests indicate that the on-line computational expense for NMPC can be reduced by about two orders of magnitude with little sacrifice in performance. This talk discusses important elements of this procedure. Moreover, further refinements are presented that include experiences with warm start strategies and the examination of nominal and robust stability properties for this NMPC strategy.

Model predictive control under probability distributions. **Marc Steinbach** (Leibniz Universität Hannover, Germany) IC/MT2545/063

We consider model predictive control under the assumption that random disturbances result from a stochastic process with known probability distribution. A dynamic stochastic programming approach is proposed to achieve optimal performance on average while ensuring that later disturbances can always be corrected. We present a suitable interior point method for solving the resulting large structured optimization problems, and algorithmic aspects regarding computational complexity are discussed. A continuously operating distillation process with a feed tank buffering uncertain inflows serves to illustrate the approach. We study a simple linear-quadratic stochastic tracking model and an integrated model with differential-algebraic equations as dynamic constraints in the stochastic program. Computational results will be presented.

Conic programming formulations for robust MPC. **Moritz Diehl** (Katholieke Universiteit Leuven, Belgium) IC/MT1091/063

In this talk we treat the robust min-max model predictive control (MPC) formulation for linearly constrained polytopic systems with quadratic cost, and show that it can be cast as a specific conic program, namely a quadratically constrained quadratic program (QCQP). To derive this result, we use the rigorous closed loop formulation of min-max MPC, and show that any such min-max MPC problem with convex costs and constraints can be cast as a finite dimensional convex optimization problem, with the QCQP arising from quadratic costs as a special case. At the base of the proof is a lemma showing the convexity of the dynamic programming cost-to-go, which implies that the worst case on an infinite polytopic set is assumed on one of its finitely many vertices. As the approach is based on a scenario tree formulation, the number of variables in this problem grows exponentially with the horizon length. Fortunately, the QCQP is tree structured, and can thus be efficiently solved by specially tailored interior-point methods whose computational costs are linear in the number of variables. The new formulation as a tree sparse QCQP thus promises to facilitate the online solution of the rigorous min-max MPC problem with quadratic costs.

Efficient robust optimization for robust control with constraints. **Eric Kerrigan** (Imperial College London, UK), Paul Goulart (University of Cambridge, UK) IC/MT1587/063

In this talk we present an efficient computational technique for the optimal control of linear discrete-time systems subject to bounded disturbances and linear constraints on the states and inputs. The problem of computing an optimal state feedback control policy over a finite horizon, given the current state, is nonconvex. A recent breakthrough has been the application of robust optimization techniques to reparameterize this problem as a convex program. While the reparameterized problem is theoretically tractable, the number of variables is quadratic in the horizon length and has no apparent exploitable structure. We focus on the situation when the disturbance set is norm bounded and the cost function to be minimized is quadratic in the states and inputs. In this case a sparse problem structure can be recovered via introduction of state-like variables and decomposition of the problem into a set of coupled finite horizon control problems. This decomposed problem can then be formulated as a highly structured quadratic program, solvable by a primal-dual interior-point method for which each iteration requires a number of operations that increases cubicly with the horizon length. This cubic iteration time can be guaranteed using a standard Riccati-based block factorization technique from discrete-time optimal control. Numerical results will be presented, using a standard sparse primal-dual interior point solver, that illustrate the efficiency of this approach.

IC/MP291/063: Geometric optimisation in linear algebra, signal processing and control.

Organiser: Knut Hüper (NICTA, Australia)
Co-organiser: Uwe Helmke (Julius-Maximilians-Universität Würzburg, Germany)

This minisymposium focuses on geometrically constrained optimisation tasks, with a wide range of applications in systems and control, numerical linear algebra, signal processing, computer vision and statistics. Recently, differential geometric ideas have been combined with nonlinear optimisation methods to solve complicated and highly non-convex optimisation tasks, thus enabling one to tackle advanced engineering applications that cannot be easily approached using more standard convex or unconstrained optimisation ideas. The minisymposium will meet the challenge of providing efficient mathematical tools for geometrically structured optimisation problems by bringing together leading experts in this quickly growing area. Current research in this field is focused on

(i) development of convergence results

(ii) generalisations to non-Riemannian settings

(iii) investigations on new application areas.

All three directions will be represented, thus allowing a broad overview on recent developments.

Optimization algorithms for computing numerical ranges and the tensor SVD. **Gunther Dirr** (Julius-Maximilians-Universität Würzburg, Germany), Uwe Helmke (Julius-Maximilians-Universität Würzburg, Germany), Oana Morar (Universität Würzburg, Germany) IC/MT1999/063

A number of interesting computational problems in linear algebra and quantum computing can be formulated as the task of optimizing trace functions on unitary orbits of elements in a tensor product of complex vector spaces. Explicitly, we consider the linear action of certain subgroups K of the unitary group $U(n)$, acting on the complex Hilbert space $H := \mathbb{C}^{n_1} \otimes \cdots \otimes \mathbb{C}^{n_r}$, $n = n_1 + \cdots + n_r$ in the natural way. For any two elements $c, a \in H$ we study the geometry of the subset

$$W_K(c,a) := \{\langle c, g \cdot a\rangle | g \in K\}$$

of the complex plane. The set $W_K(c,a)$ is a generalization of the C-numerical range from operator theory. It also connects to quantum computing and the tensor SVD – an efficient tool for data compression in pattern recognition. These connections will be outlined in the talk. Geometric optimization algorithms for maximizing the real part function $z \mapsto \mathrm{Re}(z)$ on $W_K(c,a)$ are developed.

Vector transport on manifolds. **Pierre-Antoine Absil** (Université Catholique de Louvain, Belgium), Robert Mahony (Australian National University), Rodolphe Sepulchre (Université de Liège, Belgium) IC/MT297/063

We consider the problem of finding an extremum of a smooth real-valued function on a smooth manifold where Hessian information is not available. Several optimization algorithms on Euclidean space (such as quasi-Newton and conjugate gradient methods) achieve superlinear convergence without making use of the Hessian of the cost function. These algorithms gather second-order information on the cost function by *comparing* gradient vectors at various neighboring points. To generalize this idea on smooth manifolds, one must overcome the difficulty that the gradient vectors at two different points of the manifold belong to two different tangent spaces and cannot be compared directly. When the manifold is endowed with an affine connection, the classical remedy is to use parallel translation to move one of the tangent vectors along a geodesic between the two points. However, computing parallel translation requires the solution of a set of ordinary differential equations that rarely has a closed-form solution and may be as computationally challenging as the original optimization problem.

In this work, we define sufficient properties for a generalization of the parallel translation, called *vector transport*. We show that in superlinear optimization algorithms on manifolds, parallel translation can be replaced by any vector transport without affecting the superlinear convergence. We also give examples of vector transports that are algebraically and computationally simpler than the parallel translation for a number of problems of practical interest. In conclusion, the notion of vector transport makes it possible alleviate the computational burden associated with comparing tangent vectors at various points of a manifold, without compromising the convergence properties of the optimization scheme.

A Newton–Stiefel method using the Cayley transformation. **Paul Van Dooren** (Universite Catholique de Louvain, Belgium), Catherine Fraikin (Universite Catholique de Louvain, Belgium), Knut Hüper (NICTA, Australia) IC/MT378/063

We present a parameterization of the Stiefel manifold that allows to perform a Newton step (constrained to the Stiefel manifold) in a relatively simple manner. The parameterization is based on the Cayley transformation which maps skew symmetric matrices into orthogonal matrices. We then apply this technique to a problem occurring in the analysis of graphs [1].

We also illustrate the local quadratic convergence of this method using examples coming from [1].

FastICA, Rayleigh-quotient iteration and some generalisations. **Knut Hüper** (NICTA, Australia) IC/MT1942/063

One of the state of the art algorithms for linear Independent Component Analysis in Signal Processing is FastICA, developed by the Finnish school. This very efficient algorithm enjoys nice interpretations similar to the socalled Rayleigh-Quotient-Iteration (RQI) well known to the Numerical Linear Algebra community. It can be considered as an optimisation procedure on a manifold related to intrinsic Newton-type iterations. We will discuss some of the known facts of FastICA and then present more recent results towards parallel implementations and better convergence properties.

IC/MP685/063: Symbolic and numerical computations for convex analysis.

Organiser: Yves Lucet (University of British Columbia, Canada)

Convex optimization is a fundamental branch of optimization. It provides a suitable framework from both a theoretical and a practical point of view for many problems, classical (such as image reconstruction) and contemporary (such as semidefinite programming). In this minisymposium, the speakers will discuss convex optimization problems and associated objects from a computational point of view. The algorithms presented will include purely symbolic algorithms using modern computer algebra systems, numerical algorithms adapted from computational geometry, hybrid symbolic–numeric algorithms, and optimization algorithms tailored to the numerical computation of specific convex objects.

The authors will focus on a class of functions that allows hybrid symbolic–numeric computations of convex transforms; on the symbolic computation of Fenchel conjugates; on the numerical computation of the cone of autocorrelated components; and on new principle in medical imaging called thermo-acoustic tomography.

Hybrid symbolic–numeric algorithms for computational convex analysis. **Yves Lucet** (University of British Columbia, Canada) IC/MT686/063

Computational convex analysis focuses on developing efficient tools to compute fundamental transforms arising in convex analysis. Symbolic computation tools have been developed, and have allowed more insight into the calculation of the Fenchel conjugate and related transforms. When such tools are not applicable e.g. when there is no closed form, fast transform algorithms perform numerical computation efficiently.

However, all fast transform algorithms rely on discretizations of the input and output functions, where the accuracy of the approximation is at best first-order. Moreover, they do not allow to easily compose several transforms. On the contrary, we consider the class of piecewise linear-quadratic functions which, being closed under the most relevant operations in convex analysis, allows the robust numerical computation of compositions of transforms such as the recently investigated proximal average. The algorithms presented are hybrid symbolic-numeric: they first compute a piecewise-linear quadratic approximation of the function, and then manipulate the approximation symbolically, thereby allowing a robust convex calculus.

Starting from the drawbacks of fast algorithms, we will introduce the class of piecewise-linear quadratic functions along with efficient algorithms to manipulate such functions.

Work done in collaboration with H. Bauschke and M. Trienis.

A fully-nonlinear partial differential equation for the convex envelope. **Adam Oberman** (Simon Fraser University, Canada) IC/MT5021/063

In this talk we introduce a new fully nonlinear Partial Differential Equation for the Convex Envelope of a given function. The equation is in the form of an obstacle problem, where the obstacle is the given function, and the PDE involved the smallest eigenvalue of the Hessian. The equation is useful for computing convex envelopes. Computational examples will be given. It also allows for a stochastic control interpretation for the convex envelope.

Some facts about the cone of vectors with autocorrelated components. **Marc Fuentes** (Université Paul Sabatier Toulouse III, France) IC/MT1320/063

In signal processing and communications, some optimization problems naturally involve the cone of *vectors with autocorrelated components* (also called *finite autocorrelation sequences*). A vector $x = (x_0, x_1, \cdots, x_n) \in \mathbb{R}^{n+1}$ is said to have autocorrelated components if there exists a vector $y = (y_0, y_1, \cdots, y_n) \in \mathbb{R}^{n+1}$ such that

$$x_k = \sum_{i=0}^{n-k} y_i\, y_{i+k} \quad \text{for all } k = 0, \cdots, n\,.$$

Surprisingly enough, this cone turns out to be convex (even if there is no direct simple proof of this property). In the present work, we pursue the works by L. Vandenberghe *et al.* in studying more thoroughly this cone (facets, extreme points, acuteness) and presenting algorithms to project a vector on it; One first effective approach to compute the projection uses interior point methods involving the polar cone. We propose here a non-convex relaxation to overcome the problem of dimensionality inherent to interior point methods and enable us to treat problems of larger size. We will also discuss about the extension in the bidimensionnal case, which can have some applications in image processing.

Mathematics involved in such an approach are: convex analysis and optimization, Toeplitz matrices, Riesz–Féjer representation theorem and trigonometric polynomials.

Perspectives in various notions of convexity. **Pierre Marechal** (Université Paul Sabatier Toulouse III, France) IC/MT1720/063

Any finite, separately convex, positively homogeneous function on $\Re^2$ is convex. This was first established by Dacorogna. We give a new and concise proof of this result, and we show that it fails in higher dimension. The key of the new proof is the notion of *perspective* of a convex function f, namely, the function $(x, y) \to y f(x/y)$, $y > 0$. In recent works by Maréchal, the perspective has been substantially generalized by considering functions of the form $(x, y) \to g(y) f(x/g(y))$, with suitable assumptions on g. Here, this *generalized perspective* is shown to be a powerful tool for the analysis of convexity properties of parametrized families of matrix functions.

IC/MP63/063: Robust optimization.

Organiser: Kurt Marti (Universität der Bundeswehr München, Germany)
Co-organiser: Volker Schulz (Universität Trier, Germany)
Co-organiser: Thomas Vietor (Ford Werke, Köln, Germany)

In Robust Optimization only partial information is known about the model parameters. This must be taken into account in order to reach optimal decisions/designs which are the least sensitive with respect to parameter variations in the known range of the model parameters. Hence, the original optimization problem with unknown parameters must be replaced by an appropriate deterministic substitute problem incorporating the given information about the parameters. Using decision theoretical principles, substitute problems may be obtained, depending on the available information about the type of uncertainty; e.g., by using minimax- or expectation-operators. Typical substitute problems demand then the minimization of the maximum or expected total costs (initial plus recourse costs) subject to remaining (mostly simple) design constraints, or the minimization of a (simple) cost function subject to reliability constraints involving the probability of structural/system failure/survival. Hence, a first goal of this Minisymposium is to present actual methods for coping with several types of uncertainty in order to get *robust*, hence, most parameter-insensitive optimal decisions/designs. On the other hand, since material, model and design parameters have a stochastic character, in many application areas the importance of the stochastic modelling have been accepted more and more.

Increased demand for robust optimization methods arises in many technical/industrial areas like aerospace development, passenger vehicle engineering, railway engineering, construction of ships. Thus, the second objective of this Minisymposium is to support the exchange between different areas with theoretical and practical focus. This will contribute to an extended view in application areas which includes stochastic modelling and optimization. Furthermore the demands of application areas are formulated and communicated to areas with more theoretical background. This Minisymposium continues a series of Minisymposia on design methods under stochastic uncertainty organized within GAMM.

Stochastic quadratic programming techniques for finding robust optimal designs of plastic mechanical structures. **Kurt Marti** (Universität der Bundeswehr München, Germany) IC/MT1229/063

Problems from plastic analysis and optimal plastic design are based on the convex, linear or linearized yield/strenght condition and the linear equilibrium equation for the stress (state) vector. In practice, one has to take into account stochastic variations of the model parameters (e.g. yield stresses, plastic capacities, external load factors, cost factors, etc.). Hence, in order to get robust optimal load factors, robust optimal designs, resp., the basic plastic analysis or optimal plastic design problem with random parameters must be replaced by an appropriate deterministic substitute problem. Instead of calculating approximatively the probability of failure/survival based on a certain choice of (approximate) failure modes, a direct approach is proposed based on the primary costs (weight, volume, costs of construction, costs for missing carrying capacity, etc.) and the recourse costs (e.g. costs for repair, compensation for weakness within the strucutre, damage, failure, etc.). Based on the mechanical survival conditions of plasticity theory, a quadratic error/loss criterion is developed. The minimum recourse costs can be determined then by solving an optimization problem having a quadratic objective function and linear constraints. For each vector a of model parameters and each design vector x, one obtains then an explicit representation of the "best" internal load distribution F*. Moreover, also the expected recourse costs can be determined explicitly. Consequently an explicit finite dimensional parameter optimization problem results for finding a robust optimal design x*. The analytical properties of the resulting problem are discussed, and applications, such as limit load/shakedown analysis, are considered.

Optimal design of frames under stochastic uncertainties. **Simone Zier** (Universität der Bundeswehr München, Germany) IC/MT1882/063

Structural optimization is an interesting area on which lots of research has already been done. Using the first collapse-theorem the necessary and sufficient constraints of a structure consist of the yield condition and the equilibrium condition. In the recent field of research stochastic uncertainties has been taken into account. This leads to a stochastic optimization problem which cannot be solved using the traditional methods. Instead of that appropriate (deterministic) substitute problems must be formulated.

In the following the design of frames is treated where the load is supposed to be stochastic. Here both forces and moments have to be taken into consideration. The recourse problem will be formulated in general and in the standard form of stochastic linear programming (SLP). Since the original problem is not a linear one, it is necessary to make some approximations and assumptions. After the formulation of the stochastic optimization problem the recourse problem with discretization and the expected value problem are introduced as representatives of substitute problems. Subsequently, optimization results using these methods for the robust optimal design of a storey-frame are presented.

Optimal control of robots under stochastic uncertainty: robust feedback controls. **Michael Schacher** (Universität der Bundeswehr München, Germany) IC/MT1878/063

The most important aspect in the optimal control and design of manipulators is the determination of the basic movement, i.e. the calculation of the optimal trajectory on which the robot has to move. Having an optimal reference trajectory and an optimal open-loop control, there is the need of control corrections by applying a certain feedback control. Different attempts exist for this.

In this presentation a method will be shown which is based on classical control theory, that works with cost functions being minimized. The aim is to take into account stochastic parameter varations in order to obtain robust optimal feedback controls.

After Taylor expansion to calculate expected cost functions and a few transformations it is possible to find an appropriate deterministic substitute control problem: Retaining only linear terms, approximation of expectations and variances of the expected cost function can be obtained. Furthermore, it is necessary to discretisize the objective function and the differential equations. This is handled by means of Splines.

Using stochastic optimization methods, random parameter variations can be incorporated into the optimal control process. Hence, robust optimal feedback controls are obtained.

Variation methods and discrete optimization principles in lattice geometry. **Vladimir Kobelev** (Universität Siegen, Germany) IC/MT3267/063

The contemporary knowledge about the robust discrete optimization is basically restricted to the direct numerical solution of the integer optimization problems. In the present talk we try to establish the theoretical foundation for the discrete optimization and introduce the basic variation principles of lattice geometry. The lattice geometry is essentially the based on quantum calculus of V. Kac and P. Cheung. The objects of lattice geometry - metric tensor, tangent vectors, connections, curvature tensor - appears similar to the corresponding objects of classical differential geometry, but differ from them in some important aspects. The principles of variational lattice calculus are derived. The application of lattice geometry to the robust optimization of discrete geometrical structures is discussed.

IC/MP63/063: Robust optimization. #2

Organiser: Kurt Marti (Universität der Bundeswehr München, Germany)
Co-organiser: Volker Schulz (Universität Trier, Germany)
Co-organiser: Thomas Vietor (Ford Werke, Köln, Germany)

(For abstract, see session #1 above.)

Different methods for robust design and stochastic optimization in vehicle engineering. **Thomas Vietor** (Ford Werke, Köln, Germany) IC/MT1150/063

The development of a passenger car is a multidisciplinary task. The vehicle has to fulfill demands out of different technical attributes beside non-technical requirements like styling and costs. Very often demands out of these areas are conflicting. One main problem is the variability of mechanical quantities responsible for the performance and customer perception of a car. To overcome this, the extension of the conventional deterministic oriented development process to a process which includes stochastic quantities is necessary. In this presentation the current deterministic approach is described briefly. In a first extended version of the process the variability of material parameters is included. In further steps the formulation and solution of stochastic optimization problems for sub-problems are necessary. Finally the complete approach should fully integrate the variability of stochastic quantities.
As extension to already published papers from the same authors in this presentation different approaches to robust design and stochastic optimization are compared. In this comparison well known-methods like first order second moment approaches are included as well as the use of simple Monte-Carlo simulations. Based on the complexity and effort of the different structural analysis methods for different attributes and the number of required function calls a suitable method can be selected. The comparison is extended to selected commercial software packages. For industrial applications commercial software is normally preferred because of the robustness of the software, the well designed user-interface, good documentation and the offered support. In this presentation the authors will investigate the theoretical background of some of the offered commercial software programs and study if they can be applied to real-world examples.

Work done together with Simon van den Akker and Esben Lindgaard Olesen.

Reliability-based optimization using a decoupling approach and reliability sensitivity. **Marcos Valdebenito** (Universität Innsbruck, Austria), Gerhart Schuëller (Universität Innsbruck, Austria) IC/MT2261/063

Reliability-based optimization (RBO) is a challenging task that, on one hand, involves the estimation of the reliability of a structure with respect to a certain limit state considering the uncertainty in loading and/or structural properties. On the other hand, it also involves the solution of an optimization problem. This usually requires a large number of reliability estimations in order to find a design that better fulfills the design requirements (constraints) and minimizes a certain objective function. Analytical solutions for the reliability problem are quite limited; generally it is necessary to apply simulation techniques, which are numerically expensive though. Although significant progress has been achieved recently in the latter field and now reliability analyses can be performed for large structures involving many uncertain parameters, the computational efforts involved in simulation procedures is still considerable. Hence this contribution analyzes the use of approximate measures of the reliability sensitivity (derivatives of the failure probability with respect to the design parameters) which are calculated using the information generated at the reliability estimation stage. The approximate reliability sensitivities, calculated based on the concepts proposed in [1], is combined with a decoupling approach, developed in [2] and further studied in [3], in order to reduce the numerical costs involved in the RBO problem. Examples are shown in order to discuss the advantages and drawbacks of the implemented method.

Stochastic programming in financial and energy markets. **Marc Steinbach** (Leibniz Universität Hannover, Germany) IC/MT2918/063

Robustness in the context of trading strategies often means optimal long-term performance (repeated decisions) or mean-risk optimization (one-time decisions), leading to possibly nonlinear multistage stochastic programs. We discuss applications in financial and energy markets and present interior-point based solution algorithms that can be adapted to the specific problem structure. Computational results illustrate the stochastic models and the efficiency of our solution approach.

Avoidance of random obstacles by means of probabilistic constraints. **René Henrion** (WIAS Berlin, Germany) IC/MT2116/063

Obstacle avoidance is an important issue in manufacturing processes or robotics. If only imprecise information is available, it makes sense to understand the obstacle as a random object. Modeling the avoidance of such random obstacles can be done in various ways, the most reasonable of which seems to consist in the formulation of probabilistic constraints. The talk presents shortest path models for pointwise and uniform probabilistic constraints in the case of both the obstacle and the manoeuvrable body being finite unions of convex polytopes. Solution approaches are discussed for the special case of multivariate normal data for the obstacle position in the configuration space. The methods require fast calculation of normal probabilities of polytopes (or equivalently: singular normal distributions). We apply a method based on an inclusion/exclusion formula which allows efficiently to calculate these probabilities along with their gradients with respect to moving position.

IC/MP704/063: Optimal control and stability analysis in dynamical systems, involving parameters.

Organiser: Mihai-Emilian Popescu (ISMMA-Bucharest, Romania)

We consider affine controlled systems:

$$\dot{x} = Y(x(t)) + \sum_{i=1}^{m} X_i(x(t)), \quad x(0) = x_0$$

where $u = (u_1, ..., u_m) \in U = L^2([0,T], \mathbb{R}^m)$. Applications are as follows.

1) Optimal problem: determine the minimum of functionals $J(u) = \int_0^T ah(x_u(t)) + b\varphi(X_u) + \frac{1}{2}cg(X_u)$, with $X_u = Y(x_u) + \sum_{i=1}^m X_i(x_u)$. Here x_u is the integral curve of X_u with origin x_0 and final point x_1. This optimum problem minimizes the totally energy with constraints to be tangentially at affine distribution.
2) The objective of this study is the determination a sweep solution for the class of quadratic functionals with constraints represented by quasi-linear controlled systems with a small parameters. Out of necessary conditions of extremum resulted from the vanishing of the first order differential of the extremized functional, we shall determine to zeroth order solution which corresponds to small parameter equal zero.

The solutions of the systems in variations of the necessary conditions of extremum represents the first-order solution for small parameter different of zero. An approximate solution is obtained as the sum of the zeroth- and first-order solutions.

For a stability analysis, we consider the dynamical system: $\dot{x} = f(x,p)$, where $p \in P \subset \mathbb{R}^k$ is the space parameters which can be varied in system.

A solution $\Phi_\xi : [0,\infty) \to X$ (the state space) of the system (4) with initial point $\xi \in X$ ($\Phi_\xi(0) = \xi$ is called *asymptotically* stable if:

a) $\{\Phi_\xi(t) | t > 0\}$ is bounded (with respect to a norm $\|\cdot\|$ on X;
b) there is a $\varepsilon > 0$ such that for each solution Φ_ξ with $\|\xi - \xi'\| \le \varepsilon$, we have that $\lim_{t\to\infty} \|\Phi_\xi(t) - \Phi_{\xi'}(t^*)\| = 0$.

The time function $t^* : \mathbb{R}_+ \to \mathbb{R}_+$ is defined by

$$\|\Phi_\xi(t) - \Phi_{\xi'}(t^*)\| = \min\{\|\Phi_\xi(t) - \Phi_{\xi'}(t')\| | t' > 0\}.$$

For $t = t^*$ the system is called Liapunov-stable, and the value ε is a measure of the stability of Φ_ξ.

The ball $K(\xi) = \{\xi \in X | \|\xi - \xi'\| < \varepsilon\}$ represents a domain of attraction of a stable solution Φ_ξ. $K(\xi)$ is an open set, therefore $\Phi_{\xi'}$ is also a stable solution for all $\xi' \in K(\xi)$, probably with another measure ε' of stability.

Applications of this method include:

1) One obtains the method for analysis the stability in the class of considered dynamical system.
2) Stability and performance of discrete time residual generators. This study presents a new design method for discrete time residual generators. The fault detection problem is formulated in terms of H_2 and H_∞-type optimization.

Weight-function method in stability study. **Ion Stroe** (Politehnica University of Bucharest, Romania) IC/MT945/063

A new method for systems stability analysis is presented. This method is called weight functions method and it replaces the problem of Liapunov function finding with a problem of finding a number of functions (weight functions) equal to the number of first order differential equations describing the system. It is known that there are not general methods for finding Liapunov functions. The weight functions method is simpler than the classical method since one function at a time has to found. This methodŠs conditions of solution stability for linear and nonlinear systems are presented and holonomic systems with dependent variables are analysed.

Stability and robustness properties for a class of discrete-time residual generators. **Adrian-Mihail Stoica** (Universitatea Tehnică Bucarest, Romania) IC/MT1026/063

The paper presents a new design methodology for residual generators with observer-based structure for which fault detection and disturbance attenuation conditions are determined. The developments are based on H_2 and H_∞ optimisation methods in the discrete-time framework and the solvability conditions are expressed in terms of an appropriate system of matrix inequalities. An important advantage of the proposed approach is that it can be easily extended to other classes of systems (stochastic systems, sampled-data systems, etc.) for which disturbance attenuation type results are available. Robustness properties with respect to parametric uncertainty are also analysed. The theoretical results are illustrated by a case study concerning the Global Positioning System (GPS) integrity monitoring.

Optimal control for quasi-linear systems with small parameters. **Mihai-Emilian Popescu** (ISMMA-Bucharest, Romania) IC/MT1072/063

The objective of this study is the determination of the solution for Bolza problems of optimum from the class of quadratic functionals. The differential restrictions are represented by quasi-linear controlled systems with a small parameter.

Out of necessary conditions of extremum resulted from vanishing of the first order differential of the extremized functional, we shall determine the zeroth order solutions which corresponds to small parameter, $\varepsilon = 0$.

The solution of the system in variations for the necessary conditions of extremum represents the first order solutions for $\varepsilon \neq 0$.

The obtained approximate solution is the sum of the zeroth and first order solutions.

An important result is that on the admissible trajectory $\delta x_0 = 0$ we have variation of adjoint variable, $\delta\lambda_0 \neq 0$ and, hence, the variation δu of the control on the extremal is different from zero. This correspond to the fact that the admissible trajectory is a neighboring optimal trajectory.

Thus, the first order solution is the neighboring optimal trajectory for a given value of the small parameter.

In the previously treated cases, the admissible trajectory could not be a neighboring optimal trajectory, the property we have stated being satisfied only for the analyzed case of the nonlinear systems with a small parameter.

A method for optimal control in boundary-layer flow. **Alexandru Dumitrache** (ISMMA - Bucharest, Romania) IC/MT3084/063

In this paper is presented a methodology for active flow control which couples the time-dependent Navier–Stokes system with an adjoint Navier–Stokes system and optimality conditions from which unsteady flow fields and controls (e.g., actuators), may be determined. The problem of boundary layer instability suppression through wave cancellation is used as the initial validation case to test the methodology.

The objective of control is to match the stress vector along a portion of the boundary to a given vector; instability suppression is achieved by choosing the given vector to be that of a steady base flow. Control is realized through the injection or suction of fluid through a single oriffice on the boundary. The present method may be applied to separation control, relaminarization, and turbulence control applications.

IC/MP273/063: Recent advances in derivative-free optimization.

Organiser: Virginia Torczon (College of William and Mary, USA)
Co-organiser: Robert Lewis (College of William and Mary, USA)

The optimization of complex systems often involves simulation codes for which either derivatives have not been provided or approximations of derivatives are problematic. Furthermore, the computational costs associated with the simulations can be appreciable. Recent research efforts in derivative-free optimization have focused on effective algorithmic techniques for challenges such as handling general nonlinear constraints, approximating curvature information, and distributing the computing. The aim of this minisymposium is to report both the theoretical and computational advances made in these arenas.

Sparsity of the average-curvature information matrix. **Trond Steihaug** (University of Bergen, Norway), Lennart Frimannslund (Universitetet i Bergen, Norway) IC/MT2174/063

The class of Generating Set Search (GSS) Methods is a large class within derivative free optimization methods. We present a GSS method which uses average curvature to generate the search directions. If the function that is minimized is smooth then the average curvature will be a good approximation to the Hessian matrix (and exact for quadratic functions)

Some functions are expensive to evaluate accurately, but cheap to evaluate approximately. The approximated function can be regarded as the original function subject to numerical noise and the function will be non-smooth. We show that partial separability properties can still be exploited in the context of an optimization method although the original function is distorted by noise. We show this by introducing the covariation graph of the variables which may be derived from a data dependency graph. The average curvature can be computed efficiently using information about the covariation graph.

In the context of computing the curvature information matrix, we encounter a subproblem of selecting rows from a matrix, where the number of rows is much greater than the number of columns, to obtain a full rank and well-conditioned matrix with minimum effort. Finding the optimal solution to this problem is an open problem. We present an efficient heuristic solution.

The theoretical framework we use for computing the curvature information matrix can also be used for approximating Hessians in other derivative free optimization methods.

This is joint work with Lennart Frimannslund, Department of Informatics,University of Bergen.

Sequential penalty derivative-free methods for nonlinear constrained optimization. **Giampaolo Liuzzi** (Università degli Studi di Roma "La Sapienza", Italy), Stefano Lucidi (Università degli Studi di Roma "La Sapienza", Italy), Marco Sciandrone (Università degli Studi di Firenze, Italy) IC/MT1436/063

We consider the problem of minimizing a continuously differentiable function of several variables subject to smooth nonlinear constraints. We assume that the first order derivatives of the objective function and of the constraints can be neither calculated nor approximated explicitly. This class of problems arises in many industrial and scientific applications and this motivates the increasing interest in the study of derivative-free methods. In this work we propose new globally convergent methods based on smooth sequential penalty functions. Furthermore, we show the numerical results of computational experiments performed on standard test problems.

Augmented Lagrangian generating-set search for solving nonlinear constrained optimization problems. **Virginia Torczon** (College of William and Mary, USA), Robert Lewis (College of William and Mary, USA) IC/MT3155/063

We discuss an augmented Lagrangian approach to applying generating set search to nonlinear programming. The approach is based on the approximate minimization, with a suitable derivative-free stopping criterion, of a sequence of augmented Lagrangian relaxations of the original problem, with bound and general linear constraints kept explicit. We highlight the analytical results underlying the approach and provide numerical illustrations. We also discuss strategies for active set identification and techniques for accelerating the overall optimization process.

An asynchronous parallel derivative-free software package for handling nonlinear constraints. **Joshua Griffin** (Sandia National Laboratories, USA), Tamara Kolda (Sandia National Laboratories, USA) IC/MT5025/063

Many real-life optimization problems present formidable challenges despite having a relatively small number of independent variables. Difficulties can arise from nonsmoothness, discontinuities, and noise. Further, function evaluations typically involves calling unwieldy CPU-intensive simulation software that may periodically crash. In this context, we present a globally convergent derivative-free method for nonlinear programming based on generating set search. Linear constraints are handled using conforming search directions. Several options for handling nonlinear constraints are explored, including an augmented Lagrangian approach. All methods are implemented asynchronously in parallel. We present extensive test results using the CUTEr test set.

IC/MP66/063: Algorithms for nonlinear optimization.

Organiser: Ya-xiang Yuan (Chinese Academy of Sciences)

Research on algorithms for nonlinear optimization is one of the very active research directions in optimization. In recent years there are many researches on large scale nonlinear optimization, special structured optimization problems and new type of algorithms (such as the filter methods and trust-region methods).

Global minimization on quadratic least-squares problems. **Xin Liu** (Chinese Academy of Sciences) IC/MT4369/063

We consider the global minimization on quadratic least squares(QLS) problems, which is a widely used model appearing in various areas such as industry, computational biology and so on. By discussing the properties of the local minima of QLS problems, we present some ideas for solving these problems efficiently.

On projected gradient methods for regularizing reconstruction of synchrotron radiation spectra distribution function. **Yanfei Wang** (Chinese Academy of Sciences) IC/MT2619/063

The theory of synchrotron radiation (SR) has been well-understood and published. We study the numerical methods for the reconstruction of the spectral distribution function of SR by measurement of the attenuation of the SR energy spectrum. The reconstruction of the spectral distribution function of SR is an ill-posed integral operator equation of the first kind. Therefore, how to overcome the ill-posedness is a major task in numerical computation. We study projected gradient meth-

ods for the regularized problem with nonnegative constraints. The feasibility of the method is studied in detail by using a hypothetical SR spectrum. The applied results of the spectrum of 4W1B beamline in BSRF (Beijing Synchrotron Radiation Facility) are shown. Work done in collaboration with Y.Du and T.Hu.

On adaptive step-size selections in gradient methods. **Gaetano Zanghirati** (University of Ferrara, Italy), Giacomo Frassoldati (Modena, Italy), Luca Zanni (Università degli Studi di Modena e Reggio Emilia, Italy) IC/MT2782/063

In recent years a number of different proposals for the selection of the step-size have largely improved the gradient-based methods, in the case of both constrained and unconstrained nonlinear optimization. Many of these proposals aim to achieve a good convergence rate by exploiting the Barzilai-Borwein (BB) step-sizes. To this purpose, several modifications of the original BB idea have been investigated (step-size alternations, cyclic step-sizes, adaptive selections) and have clearly shown their benefits. Motivated by the effectiveness of these modified BB rules, we propose a simple adaptive selection where the standard BB rule is alternated with a new step-size, which gets meaningful convergence rate improvements when compared with other recent BB-like gradient schemes. The actual behavior of the new method is shown on a set of well known test problems, as well as on a real-world application.

Conjugate-gradient methods in Banach spaces. **Ivie Stein** (The University of Toledo, USA) IC/MT2573/063

One purpose of this paper is to extend the conjugate gradient method to minimize functions on Banach Spaces that are norm reflexive and strictly convex. The algorithms in this paper are based upon the notion of the metric gradient defined by Michael Golomb and Richard Tapia (Numer. Math. 20 (1972) 115-124). Generalizations have been made for the algorithms of Daniel, Polak-Ribiere and Fletcher-Reeves. The primary purpose here is to present applications including problems in differential equations and the calculus of variations where the Banach spaces are Sobolev Spaces.

IC/MP66/063: Algorithms for nonlinear optimization. #2

Organiser: Ya-xiang Yuan (Chinese Academy of Sciences)

(For abstract, see session #1 above.)

A trust-region-type regularization of Newton's method. **Coralia Cartis** (Rutherford Appleton Laboratory, UK), Nicholas Gould (University of Oxford, UK), Philippe Toint (FUNDP Namur, Belgium) IC/MT2742/063

A new regularization technique for Newton's method with strong global convergence and good complexity properties was recently proposed (Nesterov & Polyak, 2006). In this, an improved estimate of the solution is computed by finding the global minimizer of a cubic model of the objective function, and there is an obvious connection to trust region methods. We address the challenges of making such an algorithm implementable and computationally efficient. The cubic model may be approximately minimized either explicitly, using a Krylov approach, or implicitly by solving a bi-level univariate minimization problem involving a sequence of trust-region subproblems as a function of their radii. Compared to existing strategies, apart from overall efficiency of this new approach, we are interested in the performance on problems for which NewtonŠs method performs poorly, because of ill-conditioning or singularity.

A new trust-region algorithm for nonlinear constrained optimization. **Niu Lingfeng** (Chinese Academy of Sciences), Ya-xiang Yuan (Chinese Academy of Sciences) IC/MT2325/063

We propose a new trust region algorithm for nonlinear constrained optimization problems. In each iteration of our algorithm, the trial step is computed by minimizing a quadratic approximation to the augmented Lagrangian function in the trust region. Based on the model problem, we give a new Lagrangian multiplier estimation and the corresponding formula for the actual/predicted reduction. A penalty function procedure combing with a new filter technique is used to force convergence when the initial values of the variables are far from the solution. The second order correction technique is utilized to avoid the Maratos effect. We report numerical results for a set of constrained problems from the CUTEr collection. Global convergence and fast local convergence for the test problems are observed.

An affine-scaling interior-point CBB method for box-constrained optimization. **William Hager** (University of Florida, USA), Hongchao Zhang (University of Minnesota, USA) IC/MT2539/063

Our algorithm combines an affine scaling approach with a cyclic Barzilai–Borwein (BB) gradient method. Global convergence is established along with local $\mathbb{R}$-linear convergence at a nondegenerate local minimizer where the second-order sufficient optimality conditions are satisfied. An application is given to penalized maximum likelihood reconstruction in positron emission tomography.

A power–penalty method for a linear complementarity problem. **Xiaoqi Yang** (Hong Kong Polytechnic University, PR China), Song Wang (University of Western Australia) IC/MT2563/063

In this paper we propose a power penalty approach to a linear complementarity problem (LCP). This approach is based on approximating the LCP by a nonlinear equation with a power penalty term. We prove that the solution to the equation converges to that of the LCP at a rate equivalent to the power used in the penalty term when the penalty parameter tends to infinity.

IC/MP5051/063: Algorithms for nonlinear optimization (II).

Organiser: Ya-xiang Yuan (Chinese Academy of Sciences)

Research on algorithms for nonlinear optimization is one of the very active research directions in optimization. In recent years there are many researches on large scale nonlinear optimization, special structured optimization problems and new type of algorithms (such as the filter methods and trust-region methods).

Solving a class of constrained black-box *inverse variational inequalities.* **Bingsheng He** (Nanjing University, PR China) IC/MT4385/063

In some practical applications of equilibrium problems, the status, instead of the variables, is required in a constrained set. The mathematical form of such problems is Find u such that $f(u) \in S$, and $(f' - f(u))^T u \leq 0$, $\forall f' \in S$, where $S = S(f) = \{f \in R^n \mid A^T f = b$ (or $A^T f \leq b)$, $f \in \mathcal{F}\}$. We call such problems inverse variational inequalities (IVI) because the variable and the function are in the opposite positions of the classical one. Usually, the function in IVI arising from real world does not have any explicit forms and we can only evaluate or observe the function value for given variables from some 'black-boxes'. For a class of constrained 'black-box' inverse variational inequalities, we present a proximal point like algorithm (PPA)-based method that only needs the function value for given variables in the solution process.

IC/MP655/064: Dynamics of equilibrium problems via game theory, evolutionary variational inequalities, complementarity and projected dynamical systems.

Organiser: Monica-Gabriela Cojocaru (University of Guelph, Canada)

The interest in modelling applied equilibrium problems (be it via Wardrop and/or Nash equilibria) has been ever increasing in the last decades, with vast ramifications and developments in nonlinear and variational analysis, in particular in the directions of projected dynamical systems, complementarity problems and variational inequalities. Game theory has also undergone a strong development, being intimately related to optimization of network problems, either from the user point of view, or from the system design/service level agreement point of view.

There are exciting theoretical and computational advances in all these areas today, and there is a considerable number of scientists with complementary expertise actively engaged in such research worldwide. This minisymposium explores the interactions among scientists in similar areas of research. It highlights important contributions to building theoretical models and simulations of applied equilibrium problems, ranging from vaccination policies to operations research and economics problems (like transportation, spatial and financial pricing, internet or energy market modelling).

A fast contraction mapping for solving multibody systems. **Alessandro Tasora** (Università degli Studi di Parma, Italy), Mihai Anitescu (Argonne National Laboratory, USA) IC/MT1672/064

The simulation of complex multibody systems with contacts and friction require a fast and robust solver for complementarity problems. This work presents an efficient method which can solve large cone-complementarity problems by means of a fixed point iteration. Our method performs like a contractive mapping, providing a monotonic approximation to the exact solution. The algorithm features high computational performance even if thousands of unilateral constraints are added to the system. Also, this scheme fits well in a real-time simulation context because it can be terminated prematurely. Differently from LCP approaches, nonlinear constraints introduced by friction in three-dimensional space are taken into accounts without using polyhedral approximations. With few modifications, a parallel version of this iterative scheme can be implemented on SIMD computing architectures.

Evaluating the Impact of Average Cost Based Contracts on the Industrial Sector in the European Emission Trading Scheme. **Giorgia Oggioni** (Università di Bergamo, Italy & KU Leuven, Belgium), Yves Smeers (Université Catholique de Louvain, Belgium) IC/MT2740/064

This paper addresses a problem arising from the combination of the restructuring of the European electricity sector and the introduction of the EU Emission Trading System (EU-ETS). Electricity intensive industrial consumers are currently facing a high price of electricity, which endangers their competitiveness and may force them to leave Europe. This would be a serious welfare loss for European countries with possibly non-environmental gain. The decrease of their European emission of CO_2 would indeed have no effect if these industries go and emit CO_2 elsewhere.
We explore the possibility of developing special contracts, which would limit the impact of CO_2 prices on electricity intensive industrial consumers. We first consider a reference situation of a perfectly competitive market where electricity prices are identical for all consumers and based on the short run marginal costs. We, then, recognize that electricity intensive consumers require a different electricity service: the bulk of their demand is indeed long-term and very high load. They are also in a position to finance the construction and the operation of large generation units. We therefore consider an alternative organization whereby electricity intensive industrial consumers pay a price corresponding to the full cost of base load plants.
We conduct a sample analysis on a prototype problem that is meant to represent Northwestern Europe (Belgium, France, Germany and the Netherlands). The models are formulated as complementarity problems and are solved in GAMS using PATH.

Electricity investments in an uncertain environment. **Yves Smeers** (Université Catholique de Louvain, Belgium) IC/MT2922/064

Investments in electricity generation are now facing considerable uncertainties, whether due to restructuring or carbon constraints. Uncertainties make investment more costly and may jeopardize security of supply. Standard minimal cost optimization models that simulate the development of competitive electricity markets in the long term are not really equipped for exploring these questions.
We consider equilibrium models of investment in competitive electricity markets that differ by the underlying representation of uncertainty. A first model assumes competing firms with different costs of capital (CAPM). A second model supposes that the firms are exposed to risk factors with different risk premium (APT). Last, we consider true stochastic equilibrium models with risk adverse firms in competition. We discuss both the formulations of these models and their casting in computable form.

Equilibrium dynamics of group vaccination strategies in a heterogeneous population with a given vaccine coverage profile. **Monica-Gabriela Cojocaru** (University of Guelph, Canada) IC/MT3119/064

We analyze here vaccination strategies games in a heterogeneous population whose individuals are partitioned in groups according to their (distinct) perceived relative risk assessments of vaccination. By relative we mean a ratio between the perceived risk of the vaccine, versus the perceived risk of becoming infected. In order to analyze such problems, we use the theories of variational inequalities and projected dynamical systems, both finite and infinite dimesional. In this work we are interested to track the dynamics of a group's equilibrium vaccination strategy, given that the vaccine coverage in the population as a whole is known. Game theoretical models illustrate how vaccine scares and declining vaccine coverage, especially in countries with voluntary vaccination policies are not isolated historical events, but rather possible instances of inherently unstable dynamics which can apply in any population under a voluntary vaccination policy. While mandatory vaccination would serve the public interest by effectively eradicating diseases, there are also implications for individual rights. Understanding and predicting long-term trends in population vaccination behaviour via game dynamic models is therefore valuable for the development of sound, evidence-based public health policy.

IC/MP655/064: Dynamics of equilibrium problems via game theory, evolutionary variational inequalities, complementarity and projected dynamical systems. #2

Organiser: Monica-Gabriela Cojocaru (University of Guelph, Canada)

(For abstract, see session #1 above.)

Frictional-contact problems with local compliance. **Jong-Shi Pang** (Rensselaer Polytechnic Institute, USA) IC/MT3151/064

A 3-dimensional frictional contact model with local compliance and damping was introduced in the 2002 Ph.D. thesis of Peng Song and was subsequently studied extensively in several papers by Song, Kumar, and Pang. In this work, we examine a variation of this model where there is no damping in the normal contact forces but there is coupled stiffness between the normal and tangential forces via body deformations. We show that this frictional contact model admits a formulation as an ordinary differential equation with a boundedly Lipschitz continuous, albeit implicitly defined, semismooth right-hand side with global linear growth. Several major consequences follow from such a formulation: (a) existence and uniqueness of a continuously differentiable solution trajectory originated from an arbitrary initial state, (b) finite contact forces that are semismooth functions of the system state, (c) semismooth dependence of the trajectory on the initial state, (d) convergence of a shooting method for solving two-point boundary problems, and (e) the absence of Zeno states. The derived results are valid for both a dynamic model and a quasistatic model, the latter being one in which inertia effects are ignored, and for a broad class of "semismoothly regular" friction cones that include the well-known quadratic Coulomb cone and its polygonal approximations.

Convergence of semi-implicit time-stepping schemes for nonsmooth dynamics. **Mihai Anitescu** (Argonne National Laboratory, USA), Florian Potra (National Institute of Standards and Technology, USA) IC/MT3221/064

In this work we present a framework for the convergence analysis in a measure differential inclusion sense of a class of time-stepping schemes for multibody dynamics with contacts, joints, and friction. This class of methods solves one linear complementarity problem per step and contains the semi-implicit Euler method, as well as trapezoidal-like methods. By using the concept of a reduced friction cone, the analysis includes a convergence result for the case that includes joints. An unexpected intermediary result is that we are able to define a discrete velocity function of bounded variation, *although the natural discrete velocity function produced by our algorithm may have unbounded variation*. Several numerical simulations are presented to demonstrate the validity of our findings.

Infinite-dimensional duality theory and applications to network equilibrium models. **Patrizia Daniele** (Università degli Studi di Catania, Italy) IC/MT3547/064

We present an infinite dimensional duality theory for optimization problems and evolutionary variational inequalities where the constraint sets are given by inequalities and equalities.

The difficulties arising from the structure of the constraint set are overcome by means of generalized constraint qualification assumptions based on the concept of quasi relative interior of a convex set.

We also apply such results to a general evolutionary network model, which includes as special cases traffic, spatial price and financial equilibrium problems.

Dynamic oligopolistic market equilibrium problem. **Annamaria Barbagallo** (Università degli Studi di Catania, Italy), Monica-Gabriela Cojocaru (University of Guelph, Canada) IC/MT5028/064

The aim of the talk is to present the oligopolistic market equilibrium problem when the data is dependent on time. We show under which assumptions the existence of the dynamic solution is ensured. We apply the regularity results proved recently in relation to this problem. Then, by means of the continuity of equilibrium solution, we can introduce a method to compute the solutions.

IC/MP295/067: Global optimization applications via SPSA.

Organiser: Rafael Banchs (Universitat Politècnica de Catalunya, Spain)
Co-organiser: Adolfo Rodriguez (University of Texas at Austin, USA)
Co-organiser: Hector Klie (University of Texas at Austin, USA)

Many of the optimization problems encountered in practical engineering and scientific applications have to deal with multiple suboptimal local solutions. In this sense, global optimization methods provide means for finding good global solutions by reducing the risk of being trapped in local solutions. The main problem of global optimization methods is that they are generally very expensive and time-consuming from the computational point of view.

The SPSA (Simultaneous Perturbation Stochastic Approximation) algorithm has lately received considerable attention because its simplicity, flexibility and low computational cost. Indeed, the algorithm only requires one or, at most, two function evaluations per iteration independently of the parameter space size in order to generate a stochastic descent direc-

tion. This constitutes a very convenient feature when dealing with large parameter spaces and/or very complex and time-expensive forward modeling algorithms. SPSA also constitutes a very attractive alternative for global optimization problems where it is unfeasible to compute function gradients.

SPSA performs random simultaneous perturbations of all model parameters to generate a descent direction at each iteration. Despite the random character of the procedure, the expected value of the computed direction is the deterministically steepest descent direction. Only two parameters, which form monotonically decreasing sequences with respect to the iteration index have to be tuned to ensure asymptotic convergence of the algorithm.

This minisymposium focuses on global optimization applications by using SPSA. After an introductory speech about the algorithm itself, some applications of the algorithm in very different engineering and scientific problems, ranging from the oil industry to natural language processing will be presented and discussed.

The magic of SPSA. **László Gerencsér** (Hungarian Academy of Sciences, Hungary), Zsuzsanna Vágó (Pázmány Péter Katolikus Egyetem, Hungary), Stacy Hill (The Johns Hopkins University, USA) IC/MT3195/067

In his seminal 1992 paper, J. Spall introduced the simultaneous perturbation stochastic approximation (SPSA), the prime targeted area being function minimization on heavy terrain: when function evaluation is expensive and noisy and gradients are not available by direct experiments. The main objective of SPSA is to achieve a prescribed accuracy with possibly smallest number of measurements.

The basic idea is a simple, but unlikely observation saying that it is possible to generate an unbiased estimator of the gradient of a quadratic function in any dimension with just two measurements. Indeed, if $f(x)$ is a quadratic function and we define the vector

$$H(x) = \frac{1}{2}(f(x+u) - f(x-u))v$$

where the random vectors u, v are such that

$$\mathrm{E}uv^T = I,$$

with I being the identity matrix, then it is easy to see that $H(x)$ is an unbiased estimator of the gradient of f at x. This simple observation proved to be amazingly useful if properly applied. The minimization of f can be carried out using H in a stochastic gradient method, thus yielding the SPSA method. This stochastic approximation scheme is similar to the well-known Kiefer-Wolfowitz scheme, but it is using just two measurements as opposed to $2p$ measurements, where p is the dimension. The clever choice of the vectors u and v is a key ingredient of SPSA.

We shall give a brief overview of the basic convergence results, including asymptotic covariance matrices, and rate of convergence for higher order moments. A few extensions of the original SPSA method will be also presented. In the second order SPSA method, also due to J. Spall, the Hessian matrix is estimated similarly to the gradient. The possibility of using higher order difference schemes to estimate the gradient will be also discussed.

A hybrid optimization approach for solving automated parameter-estimation problems. **Leticia Velazquez** (University of Texas at El Paso, USA), Hector Klie (University of Texas at Austin, USA), Mary Wheeler (University of Texas at Austin, USA), Miguel Argaez (University of Texas at El Paso, USA), Carlos Quintero (University of Texas at El Paso, USA) IC/MT4996/067

We present a hybrid optimization approach for solving automated parameter estimation problems that is based on the coupling of the Simultaneous Perturbation Stochastic Approximation and a globalized Newton–Krylov interior-point algorithm presented by Argáez *et al.* The procedure generates a surrogate model on which the interior-point algorithm can be used to find an optimal solution. We implement the hybrid optimization algorithm on several test cases, and present some encouraging numerical results.

Tuning machine-translation parameters with SPSA. **Rafael Banchs** (Universitat Politècnica de Catalunya, Spain), Patrik Lambert (Universitat Politècnica de Catalunya, Spain) IC/MT2176/067

Most of statistical machine translation systems are combinations of various models, and translation quality can be improved by adjusting the weight of each feature function in the log-linear combination. However, this optimisation problem in multiple dimensions is difficult because of three main characteristics of the objective function. Firstly, it has no analytic representation, so the gradient cannot be calculated. Secondly, it has many local minima. Finally, its evaluation has a significant computational cost.

Consequently, optimisations starting from different initial settings can converge to fairly different solutions. We present tuning experiments with the Simultaneous Perturbation Stochastic Approximation (SPSA) algorithm, and compare them to tuning with the widely used downhill simplex method. The objective of the experiment was to compare the consistency of the results over changes in initial settings. For this, we ran the algorithms from 7 different initial points and for each point, for 10 slightly different realisations.

With Chinese–English data from IWSLT 2006 machine translation evaluation, both methods showed similar performance, but SPSA was more robust to the choice of initial settings and with respect to slightly different realisations of the algorithm.

The conjugated effect of two SPSA properties not shared by the simplex method may contribute to explain this difference in stability. Firstly, SPSA search path follows in average the direction of the gradient, whereas the simplex orientation is blind. Secondly, SPSA has always a probability to go away from a zone close to a minimum, which allows it to find a lower minimum elsewhere in the search space. On the contrary, when the simplex shrinks in a zone close to a minimum, it is stuck in that zone.

SPSA for oil-parameter estimation and reservoir management. **Adolfo Rodriguez** (University of Texas at Austin, USA), Hector Klie (University of Texas at Austin, USA), Mary Wheeler (University of Texas at Austin, USA) IC/MT1498/067

The simultaneous perturbation stochastic approximation (SPSA) algorithm is emerging as a powerful but simple strategy for performing large-scale global optimization in several application settings. Two important features of this algorithm are: (1) it does not require derivative information; and, (2) the number of function evaluations is one or, at most two, independent of the size of the parameter space. In this work, we study the computational capabilities of SPSA under the view of two fundamental application from the oil industry: parameter estimation and, the optimal well placement. The parameter estimation problem (history matching) is a highly ill-posed and time-consuming task since the number of observations (on the order of hundreds to thousands) is relatively small compared to the number of parameters to be estimated (on the order of hundred of thousands to millions). To cope with this high complexity, we use SPSA in conjunction with a multiscale pa-

rameterization approach that allows us to dramatically reduce the parameter space. The estimation and sampling performed by SPSA is further enhanced by a neural learning engine that evaluates the objective function sensitivity with respect to parameter estimates in the vicinity of the most promising optimal solutions. The determination of the optimal well location is a challenging problem in oil reservoir management since it depends on both geological and fluid properties as well as on economic parameters. Traditionally, this task has been carried out by analyzing a few scenarios with a numerical reservoir simulator. This approach, however, has often led to misleading decisions with high economic impacts. SPSA offers the possibility of performing a systematic exploration of a broader set of well location and production scenarios with a lesser number of simulations. Numerical experiments show the viability of the method for addressing realistic problems.

IC/MP337/015: **Recent advances in large-scale optimization.**

Organiser: Michael Ulbrich (TU München, Germany)

Large scale optimization problems are of central importance in a wide range of applications. In particular, they arise whenever complex systems are involved in the optimization task, e.g., systems that are governed by PDEs, are coupled or networked, involve uncertainty, etc. Theory and methods for large scale optimization problems are the indispensable prerequisite for performing the crucial step from modelling and simulation to optimization and control of large systems. The aim of this minisymposium is to present important recent advances in selected fields of large scale optimization that are of general interest. The talks cover an attractive range of topics such as new algorithmic developments in large scale and infinite dimensional optimization, structure-exploiting algorithms, and challenging applications in engineering, geology, and finance.

Optimization problems in finance. **Ekkehard Sachs** (Universität Trier, Germany & Virginia Tech, USA), Kaebe Christoph (Universität Trier, Germany) IC/MT3567/015

The pricing of derivatives has gained considerable importance in the finance industry and leads to interesting problems in numerical optimization. We review some of the models for option prices and their practical application. The calibration of these models leads to optimization problem which can be large scale. We consider the numerical solution and show the efforts to reduce the complexity.

Inverse seismic wave propagation: algorithmic concepts and numerical results for real geological data. **Carsten Burstedde** (University of Texas at Austin, USA), Omar Ghattas (University of Texas at Austin, USA) IC/MT3204/015

The numerical solution of inverse problems in seismic wave propagation is a great challenge. The character of the waveforms in combination with a standard L_2 norm for the data misfit functional leads to highly nonlinear optimization problems with many local minima. A successful strategy here is to use multiscale hierarchies both in the space discretization and the signal frequencies. Alternatively, experience from computational seismology suggests to amend the data misfit term by observations of traveltime, phase shifts or more general integral transform operators. To improve the convergence of large-scale computations and accommodate different regularization approaches, we make use of limited-memory preconditioning and modifications of the Newton solver. We combine these ideas for the solution of inversion problems on real geological data and provide a variety of numerical results, and comment on the ongoing development of our massively parallel inversion code in three dimensions.

Aerodynamic shape optimization. **Volker Schulz** (Universität Trier, Germany) IC/MT1895/015

The efficient solution of aerodynamic shape optimization problems is of utmost importance for reducing fuel consumtion and/or improving aerodynamic characteristics of airplanes. This problems leads to large scale optimization problems, where the high number of variables corresponds mainly to the discretization of the PDE modeling the aerodynamic flow. One of the peculiarities of these problems lies in the fact that the flow solver to be used is mostly given from practicioners and represents a large volume of knowledge. That means that the flow solver can only be slightly changed and nevertheless an efficient optimization procedure should be constructed. Results and experiences from the German project MEGADESIGN will be presented.

Primal-dual interior-point methods for optimization problems with PDE constraints. **Michael Ulbrich** (TU München, Germany) IC/MT3237/015

Primal-dual interior-point methods have proven to be very efficient in the context of large scale nonlinear programming. In this talk, we present a convergence analysis of a primal-dual interior-point method for PDE-constrained optimization in an appropriate function space setting. Considered are optimal control problems with control constraints in L^p. The extension to state constraints is currently under investigation and we hope that we can present some progress also in this direction. It is shown that the developed primal-dual interior-point method converges globally and locally superlinearly. Not only the L^∞-setting is analyzed, but also a more involved L^q-analysis, $q < \infty$, is presented. In L^∞, the set of feasible controls contains interior points and the Fréchet differentiability of the perturbed optimality system can be shown. In the L^q-setting, which is highly relevant for PDE-constrained optimization, these nice properties are no longer available. Nevertheless, using refined techniques, a convergence analysis can be carried out. In particular, two-norm techniques and a smoothing step are required. Numerical results are presented that prove the efficiency of the method.

(Work done in collaboration with Stefan Ulbrich.)

Co-organiser: Aurea Martinez (Universidad de Vigo, Spain)

Optimal treatment planning in radiotherapy based on Boltzmann transport calculations. **Matthias Schaefer** (TU Kaiserslautern, Germany), Martin Frank (TU Kaiserslautern, Germany), Michael Herty (TU Kaiserslautern, Germany) IC/CT2114/061

A Boltzmann transport model for dose calculation in radiation therapy is considered. We formulate an optimal control problem for the desired dose. Based on this model we derive the optimality conditions for the full model as well as for approximate P_N models in 1d and 2d. We prove existence and uniqueness of the minimizer. We show that the P_N approximation of the optimality system is in fact the optimality system of the P_N approximation. Numerical results based on the P_N models in one and two dimensions are presented.

High-intensity ultrasound focusing by optimal acoustic lens design. **Slobodan Veljović** (Universität Erlangen–Nürnberg, Germany), Barbara Kaltenbacher (Universität Stuttgart, Germany) IC/CT1540/061

Shape optimization of an acoustic lens is considered. The problem comes from the usage of ultrasound in medical treatment of kidney stones. Since it can be assumed that no topology changes take place and only small geometry modifications have to be taken into account, we can work with gradient type optimization methods on a parameterization of the lens shape. For this purpose, the lens is parameterized by cubic splines and as a first step, the linear wave equation with jumping coefficients is used to represent wave propagation through the entire domain consisting of the fluid region (i.e., the human tissue) and the lens region. I.e. our model consists of the equation $\psi_{tt} - c^2\Delta\psi = 0$, where the speed of sound c is piecewise constant taking different values inside and outside of the lens. The cost functional is of tracking type to achieve an acoustic pressure distribution that exhibits a point focus at the desired location and has low amplitudes elsewhere. A sensitivity analysis is performed whose results are used in the numerical computations based on gradient methods using adjoint techniques for efficient gradient evaluation. Numerical results are presented and convergence issues as well as extension to a refined model consisting of a nonlinear wave equation in the fluid region and linear elasticity for the lens are discussed.

Optimal operation for a river fishway. **Lino Alvarez-Vazquez** (Universidad de Vigo, Spain), Aurea Martinez (Universidad de Vigo, Spain), Miguel Vazquez-Mendez (Universidade de Santiago de Compostela, Spain), Miguel Vilar (Universidade de Santiago de Compostela, Spain) IC/CT1164/061

A fishway (also known in the literature as fish ladder or fish pass) is a hydraulic structure that enable fish to overcome obstructions (dams, waterfalls, rapids...) to their spawning and other river migrations. We deal here with the more usual type of fishway: the vertical slot fishway. It consists of a rectangular channel with a sloping floor that is divided into a number of pools. Water runs downstream in this channel, through a series of vertical slots from one pool to the next one below. The water flow forms a jet at the slot, and the energy is dissipated by mixing in the pool. The fish ascends, using its burst speed, to get past the slot, then it rests in the pool till the next slot is tried.

We present a mathematical formulation of an optimal control problem related to a vertical slot fishway, where the state system is given by the shallow water equations determining the height of water and its velocity (averaged in height), the control is the normal flux of water on the inflow, and the objective function is related to the existence of rest areas for fish and a water velocity suitable for fish leaping and swimming capabilities: Our main aim consists of finding the optimal normal flux of incoming water for the vertical slot fishway so that the higher number of fish can ascend through the obstacle in the river in their best conditions.

We obtain a first order optimality condition for characterizing the optimal solutions of this problem, obtained by adjoint state techniques. From a numerical point of view, we use a characteristic-Galerkin method for solving the shallow water (Saint Venant) equations, and a derivative-free algorithm for the computation of the optimal control. Finally, we present numerical results obtained for the nine pools channel under study.

Optimal reclamation of polluted rivers. **Aurea Martinez** (Universidad de Vigo, Spain), Lino Alvarez-Vazquez (Universidad de Vigo, Spain), Miguel Vazquez-Mendez (Universidade de Santiago de Compostela, Spain), Miguel Vilar (Universidade de Santiago de Compostela, Spain) IC/CT1172/061

The main goal of this work is to use mathematical modelling and numerical optimization to obtain the optimal purification of a polluted section of a river. The most common technique for doing this consists of the injection of clear water from a reservoir in a near point. This strategy presents a high efficiency to purify polluted rivers in a short period of time. In this process of water injection the main problem consists, once the injection point is selected by geophysical reasons, of finding the minimum quantity of water which is needed to be injected into the river in order to purify it up to a fixed threshold. The goal of this paper is to determine this minimal quantity of injected water in order to ensure that the contaminant concentration in the river section is lower than fixed thresholds.

We formulate the problem as an optimal control problem, where the state system is given by the 1D shallow water equations coupled with the pollutant concentration equation, the control is the flux of injected water, and the objective function is related to the quantity of water and the pollution thresholds.

We present the mathematical formulation of the continuous problem, deriving a first order optimality condition in order to characterize the optimal solutions. We also analyse the discretization of the optimal control problem by means of a finite elements method, obtaining the discretized adjoint system and the gradient of the cost function. Finally, we deal with the numerical resolution of a realistic problem, where the optimization algorithm is introduced and computational results are provided.

Optimal control for supply-network models: adjoint calculus. **Claus Kirchner** (TU Kaiserslautern, Germany), Simone Göttlich (TU Kaiserslautern, Germany), Michael Herty (TU Kaiserslautern, Germany), Axel Klar (TU Kaiserslautern, Germany) IC/CT1914/061

We consider a PDE–based supply network model with controllable nodes for which we derive an optimal control problem and present an adjoint–based solution technique.

The supply network has two basic building blocks. The dynamics in a processor are governed by a PDE with a non-differentiable flux function. The behavior inside a queue is described by an ODE. The network model provides a framework to couple these equations at junctions. We introduce controls at certain junctions and discuss suitable cost–functionals leading to optimal control problems which we solve by a projected gradient method. The gradient information can be obtained from adjoint equations which we derived in the context of our supply network model. Finally we compare the numerical results, in particular the optimal controls, to a slightly different approach based on a mixed integer program.

Optimal control for supply-network models: mixed integer programming. **Simone Göttlich** (TU Kaiserslautern, Germany), Michael Herty (TU Kaiserslautern, Germany), Axel Klar (TU Kaiserslautern, Germany), Armin Fügenschuh (TU Darmstadt, Germany), Alexander Martin (TU Darmstadt, Germany) IC/CT2412/061

In this talk, we present a continuous model for the simulation and optimization of supply networks. We survey the underlying fundamentals, introduce a basic model based on partial and ordinary differential equations and show its relation to mixed-integer programming. This is done by applying numerical discretization schemes to the dynamics of the PDE and by approximations to the cost functional. The proposed MIP model is different from standard approaches due to its derivation from continuous dynamics. One benefit of the MIP model is the adaptivity to real-world situations by adding reasonable extensions such as bounded queues and the maintenance of processors.

Efficiency and optimization. **Vasile Postolica** (Bacau State University, Romania) IC/CT1252/006

This contributed talk is devoted to a new study concerning the main connections between efficiency and optimization. At the beginning, we present some important questions regarding efficiency and we emphasize the Pareto Optimality as one of the illustrative examples. Afterwards, following our recent concept of *approximate efficiency*, we indicate topical results obtained in infinite-dimensional spaces: strong links between efficiency, approximate efficiency, strong and vectorial optimization, potential theory and its applications through the agency of Choquet boundaries. To continue the scientific investigations, we include significant comments, pertinent remarks, adequate open problems and proper references.

Keywords: Efficiency, Approximate Efficiency, Pareto Optimality, Optimization, Potential Theory, Choquet Boundary.

On a predictor–corrector method for a class of equilibrium problems. **Vasile Preda** (University of Bucharest, Romania), Miruna Beldiman (University of Bucharest, Romania), Anton Bătătorescu (University of Bucharest, Romania) IC/CT2878/064

We consider two classes of generalized monotone functions and generalized skew symmetric functions. By applying the auxiliary principle technique, we propose and study a predictor-corrector algorithm for solving mixed quasiequilibrium problems involving σ-pseudomonotone functions with respect to a ξ-skew symmetric bifunction. It is proved the convergence of the iterative sequence under generalized pseudomonotonicity and skew-symmetry assumptions, improving some known results in the recent literature.

On Tamir's algorithm for solving the nonlinear complementarity problem. **Uwe Schaefer** (Universität Karlsruhe, Germany) IC/CT1444/064

In 1974, Tamir published an algorithm for solving the nonlinear complementarity problem for the case that the given function is a so-called Z-function. This algorithm was a generalization of Chandrasekaran's algorithm which solves the linear complementarity problem for the case that the given matrix was a so-called Z-matrix. Proving his results Tamir used the iterative processes of Gauss-Seidel and Jacobi. We present a different proof where the iterative processes of Gauss-Seidel and Jacobi are not used.

On the regularity of dynamic equilibrium problems and computational procedure. **Annamaria Barbagallo** (Università degli Studi di Catania, Italy) IC/CT715/064

The aim of the talk is to consider dynamic equilibrium problems expressed by evolutionary variational and quasi-variational inequalities and to introduce a discretization method to calculate equilibrium solutions. The computational procedure is obtained after having shown the continuity of solutions to evolutionary variational and quasi-variational inequalities. In the detail, we obtain the continuity results for strongly monotone variational and quasi-variational inequalities, making use of concepts of the sets convergence in Mosco's sense and of Minty's Lemma. Then, we extend regularity results for strictly monotone evolutionary variational and quasi-variational inequalities using a regularity procedure. Finally, taking into account of the continuity, we present a discretization procedure and then we compute, by means of a projection-contraction method, solutions of the finite-dimensional variational inequalities obtained using the discretization. At last, we construct an approximation solution with the linear interpolation.

Dimension reduction in multiobjective optimization. **Lino Costa** (Universidade do Minho, Portugal), Pedro Oliveira (Universidade do Minho, Portugal) IC/CT2246/067

In multiobjective optimization there is often the problem of the existence of a large number of objectives. For more than two objectives there is a difficulty with the representation and visualization of the solutions in the objective space. Therefore, it is not clear for the decision maker the trade-off between the different alternative solutions. Thus, this creates enormous difficulties when choosing a solution from the Pareto-optimal set and constitutes a central question in the process of decision

making. Based on statistical methods as Principle Component Analysis and Cluster Analysis, the problem of reduction of the number of objectives is addressed. Several test examples with different number of objectives have been studied in order to evaluate the process of decision making through these methods. Preliminary results indicate that this statistical approach can be a valuable tool on decision making in multiobjective optimization.

Multi-objective decomposition with applications in finance and engineering design. **Alexander Engau** (Clemson University, USA) IC/CT4282/067

Many optimization problems in finance, engineering, and numerous other fields require the simultaneous consideration of several criteria and, thus, are best modeled and solved using the methods from multiobjective programming and multicriteria optimization. A common characteristic of all these problems is that, in general, there does not exist a unique optimal solution, but a set of so-called Pareto solutions from among which the decision maker chooses based on personal preferences or additional criteria not included in the original optimization model. While a great variety of approaches exists to generate parts of the Pareto set, however, choosing a final preferred solution still remains difficult, especially if the numbers of objectives and solutions are too large to allow the effective use of an existing enumeration or visualization technique.

In remedy of these challenges and the generally high complexity encountered in real-life optimization problems, a multiobjective decomposition-coordination framework is proposed that initially decomposes the original objective function and forms a collection of smaller-sized subproblems that can be solved for their individual solution sets. To identify a common solution for all decomposed and, thus, the original problem, two subsequent coordination procedures are formulated that use the concept of epsilon-efficiency to integrate decisions on the desired tradeoffs between these individual solutions.

Two real-life applications are presented to illustrate the decomposition and the two coordination procedures for both a continuous and a discrete optimization problem. The first example is drawn from classical portfolio optimization and shows how the proposed approach enables the simultaneous consideration of several mean-variance estimators to arrive at a more reliable final investment portfolio. The second example describes a design selection problem in the context of automobile safety and shows how an initial set of simulated designs can be effectively reduced to only few efficient designs of particular interest to the designer and decision-maker.

IC/CTS4677/06: Queuing and probabilistic models.

Organiser: Ana Friedlander (Universidade Estadual de Campinas, Brazil)

On the $MX/G/1$ queueing system with first n exceptional services in each busy period. **Manju Sharma** (R B S College, Agra, India) IC/CT593/010

In this paper, we study a single-server queueing system in which customers arrive in groups of random size according to a time-homogeneous Poisson process and are served singly. The batches are served in order of their arrival, while the customers from the group are selected at random for service.The service time distribution depends on the number of customers served since the beginning of current busy period. However, it is assumed that the service time distribution becomes stable after N customers has been served in the current busy period. So, first N customers of each busy period receive exceptional services.

By using supplementary variable technique, recursion formulas are derived to obtain the generating functions of the stationary queue length distribution and the sojurn time distribution. These type of queuing systems are well applicable in many real-life situations including the modern computer and communication systems.

Cost analysis of dual machine interference model with general arrival distribution. **Sant Sharan** (Dr. RML Avadh University, Faizabad, India) IC/CT420/063

Previous authors made no attempt to discuss the cost analysis of the machine interference model with general arrival distribution $G/M/C/K/N$. In this paper, an attempt has been made to discuss the cost analysis of the same model. Upon constructing the cost function, a fast converging computer oriented N-R method has been used to solve the non-linear function, involving service rate and hyper geometric functions including other parameters in order to yield total optimal cost. Finally, an efficient evaluation of performance measure in the form of cost and the sensitivity analyses have also been presented.

Hierarchical multilevel optimization for reliability target allocation in probabilistic design of decomposed systems. **Michael Kokkolaras** (University of Michigan, Ann Arbor, USA) IC/CT2820/015

Design optimization of complex engineering systems can often be accomplished only by decomposition. The system is partitioned into subsystems, the subsystems are partitioned into components, the components into parts, and so on. The outcome of the decomposition process is a multilevel hierarchy of system-constituent elements.

In previous work, we developed analytical target cascading (ATC), a methodology for solving hierarchical multilevel optimal design problems. In ATC, system design targets are cascaded to subsystems and components using the model-based hierarchy. An optimization problem is formulated and solved for each design subproblem to minimize deviations from propagated targets. Solving the subproblems using appropriate coordination strategies yields overall system compatibility. We have also extended the deterministic ATC formulation to account for uncertainties. Uncertain design optimization variables and parameters are modeled as random variables, and all ATC optimization subproblems are reformulated as reliability-based design optimization (RBDO) problems.

In RBDO, reliability is defined as the statistical estimate of satisfying probabilistically formulated design constraints. Although reliability is nowadays considered to be a system design criterion of primary importance, its target value is prescribed more or less arbitrarily as opposed to being assigned optimally. The vast majority of RBDO methods require the specification of reliability targets for each of the probabilistic design constraints. In this work, we extend the probabilistic formulation of the analytical target cascading methodology to include reliability targets in the vector of cascaded quantities. In this manner, we achieve balanced optimality vs. reliability tradeoffs for each element of the decomposed system while satisfying the overall system reliability target.

ϵ-alternative solutions of the optimal-control problems. **Akbar H. Borzabadi** (Damghan University of Basic Sciences, Iran) IC/CT1135/006

In this paper we introduce ϵ-alternative solutions of the optimal control problems, which it seems that is useful for applications. Since in analytical discussion, extract of these solutions may be difficult, by a metamorphosis in the space of optimal control (OCP), we try to extract approximate ϵ-Alternative solutions for OCP's. Finally some numerical examples are given.

Theoretical aspects of an inexact restoration method for solving bilevel programming problems. **Ana Friedlander** (Universidade Estadual de Campinas, Brazil) IC/CT2809/063

We study theoretical properties of a method for bilevel programming problems. This method is based in the inexact restoration technique and showed a good performance on problems that fail to verify the sufficient conditions required in its convergence proof. Our goal is to fundament theoretically this behaviour.

An optimization method for locating epileptic sources: applications on realistic models of the head. **Maha Farah** (Université de Technologie Compiègne, France), Abdellatif El Badia (Université de Technologie Compiègne, France), Tuong Ha-Duong (Université de Technologie Compiègne, France) IC/CT2959/125

This paper addresses the identification of epileptic sources inside the brain knowing electromagnetic measurements on a part of the scalp. We consider the Maxwell equations on the quasi-static approach which are formulated as : $\nabla \times E = 0$, $\nabla \times B = \mu_0 (\sigma E + J^p)$ where E and B are the electric and magnetic fields, σ the conductivity and J^p the source term that we are seeking to estimate. The first equation gives $E = -\nabla V$, and from the second we have :

$$\nabla \cdot (\sigma \nabla V) = \nabla \cdot J^p$$

In this paper, we present a method to solve the EEG inverse problem, which consists to find J^p knowing σ and measurements of the electric potential V on a subset of the scalp. We assume that the head is made up of three disjoint coated domains (scalp, skull and brain), in each of which the conductivity is constant. Otherwise the geometry of these domains can be arbitrary. We consider a finite number of pointwise dipolar sources inside the brain. Assuming the number of dipoles is known, we have established an algorithm which allows us to identify their locations and moments. Our method consists in minimizing a cost function that involves the solutions computed from both the prescribed and measured data through their values inside the domain and not only on the boundary like the least square method. We have showed the robustness of the method and established the Gateaux derivative in order to use a gradient method to solve the corresponding optimization problem. Numerical experiments on realistic models with data known only on a part of the scalp have been performed. They show the robustness and the performance of our method.

Organiser: Raphael Hauser (University of Oxford, UK)

SDP approximability of relative robust QP. **Raphael Hauser** (University of Oxford, UK) IC/CT3575/067

Consider the framework in which a utility function depends on a vector of uncertain parameters which are only known to lie in a given uncertainty set. Relative robust optimisation is a framework in which the objective function is defined as the loss of utility relative to a benchmark that would choose the optimising values for the decision variables if the uncertain parameter was known. Given this so-called regret function, one seeks to minimise (over the decision variables) the pessimised (over the parameter values in the uncertainty set) regret. The resulting problem is a tri-level optimisation problem which can be approximated by a tractable conic programming problem. We investigate this approximability and identify cases in which the tractable approximation solves the original problem. The resulting technique leads to interesting applications in robust portfolio optimisation, in a setting where the performance is measured relative to a benchmark.

First-order methods for semidefinite optimization and applications. **Alexandre d'Aspremont** (Princeton University, USA) IC/CT1342/063

We present some recent results on first order methods in semidefinite optimization and discuss applications in machine learning and statistics.

Interior-point methods specialized to optimal pump-operation costs of water-distribution networks. **Aurelio Oliveira** (Universidade Estadual de Campinas, Brazil), Aline Lima (Universidade Estadual de Campinas, Brazil) IC/CT2901/063

The water supply problem aims to deliver water from reservoirs to consumer points through a network flow system. Pumps are used in order to comply with water demand and network constraints. This problem can be formulated as a network flow model using Kirchhoff's laws with additional constraints to achieve minimal pressure in the nodes and bounds on arcs. This methodology intends to minimize pumping energy costs of water distribution networks. For this purpose a specialized interior point method is developed for this system in the same fashion as it is performed for electrical power transmission systems. The resulting formulation is nonlinear. It is approached as a quadratic objective function problem subject to generalized graph with additional constraints in an iterative way generating, thus, a sequence of quadratic problems. The resulting matrix structure that arises from the interior point methods is exploited leading to smaller linear systems to compute the search directions. Computational experiments are presented, showing the robustness and speed of this approach.

A continuous Newton-type method for unconstrained optimization. **Li-Zhi Liao** (Hong Kong Baptist University) IC/CT1328/010

In this talk, we will propose a continuous Newton-type method in the form of an ordinary differential equation by combining the negative gradient and Newton's direction. It is shown that for a general function $f(x)$, our method converges globally to a connected subset of the stationary points of $f(x)$ under some mild conditions; and converges globally to a single stationary point for a real analytic function. The method reduces to the exact Newton method if the Hessian matrix of $f(x)$ is positive definite. The convergence of the new method on 18 standard test problems in the literature are also reported.

Nash-equilibrium conditions for strategic form games. **Valeriu Ungureanu** (State University of Moldova) IC/CT605/064

The notions of the Lagrange vector-function and the saddle point are introduced for normal-form strategic games. The Nash equilibrium conditions are formulated and proved. The Pareto–Nash equilibrium conditions are formulated for multi-criteria strategic form games. Other different Pareto-Nash, weak Pareto–Nash (Slater–Nash) etc. equilibrium conditions may be formulated and proved for multi-criteria games. Well-known theorems for matrix games are extended on strategic form games. Mathematical programming Kuhn–Tucker theorems are extended on strategic form games. Well-known theorems for multi-criteria optimization problems are extended on multi-criteria strategic form games. The theoretical and practical impacts of the obtained results are analyzed.

Elastic–plastic deforming of a heterogeneous media. **Victor Yanko** (Dnipropetrovs'k National University, Ukraine) IC/CT1390/006

A theoretical model which allows to define the effective elastic–plastic properties of a heterogeneous multiphase material is proposed here. It is supposed that elastic-plastic properties and the parameters describing spatial distribution of particles of each phase are known.

Firstly, some kinematical relations are derived. They include the laws of evolution of the phase relative volume as well as the symmetric second order tensor (phase tensor) which describes spatial distribution of the particles of each phase in the representative volume of the heterogeneous material. Also the relation between overall (effective) strain rate and strain rate of the phases is obtained from the condition of compatibility of deforming of all phases.

Then, with using of the equivalent inclusion method the procedure of localization is carried out. It allows to find the relations between local (phase) and effective deformation rates which includes fourth and second order strain concentration tensors. The first from them takes into account the heterogeneity of the tangent modulus, while the second tensor depends only from plastic components of local and effective strain rates and takes into account the heterogeneity of the plastic strain rate inside the material.

Finally, the procedure of homogenization is proposed. It based on condition of equality of the Cauchy stress vector which acts in the heterogeneous body and the sum of the phase stress vectors; each of them is applied to a particular phase. The resulting relation is divided to the "elastic" and "plastic" parts, what allows to find elastic L_e^H and plastic L_p^H components of the effective secant module $L_t^H = L_e^H - L_p^H$.

IC/CTS4664/06: Shape optimization.

Organiser: Mircea Lupu (Transilvania University of Brasov, Romania)
Co-organiser: Adriana Nastase (RWTH Aachen, Germany)

A level-set method for topology optimization using topological derivatives. **Samuel Amstutz** (Université d'Avignon, France), Heiko Andrä (Fraunhofer ITWM, Kaiserslautern, Germany) IC/CT2161/061

The level-set method has been recently introduced in the field of shape optimization, enabling a smooth representation of the boundaries on a fixed mesh and therefore leading to fast numerical algorithms. However, most of these algorithms use a Hamilton-Jacobi equation to connect the evolution of the level-set function with the deformation of the contours, and consequently they can hardly create new holes in the domain (at least in 2D). We propose an evolution equation for the level-set function based on a generalization of the concept of topological derivative. This results in a new algorithm allowing for all kinds of topology changes. In the talk, the method will be presented together with some numerical examples in structural optimization.

A shape optimization problem with convex constraint. **Arian Novruzi** (Université d'Ottawa, Canada) IC/CT4551/061

We consider the optimization of a shape functional over a set of 2D convex domains. This problem has been considered by M. Crouzeix, see [1], who by using surprising geometric elementary considerations proves that the solution is a polygon.

The problem represents a typical model of a larger class of problems and we consider it from a Hilbertian functional viewpoint. We find the Euler–Lagrange equation, see [2], which due to constrains invloves Radon measures. Contrary to shape optimization problems without constraint, or with equality constraints, here the Euler–Lagrange equation does not provide sufficient information to identify the solution. Using the second order necessary condition, see [3], we first characterize the solution up to a zero-measure set. Next, detailed analysis using again the second-order necessary condition leads to a complete charcterization of the regularity of the solution.

Work done in collaboration with Jimmy Lamboley and Michel Pierre, ENS Cachan, Antenne de Bretagne.

Mixed integer programming for topology optimization in sheet-metal design. **Armin Fügenschuh** (TU Darmstadt, Germany), Alexander Martin (TU Darmstadt, Germany) IC/CT4199/066

Topology optimization lies at the heart of many design tasks in mechanical engineering. For those sheet metal products that consists of a bundle of separate channels (such as conduits) we formulate the design task as a linear mixed-integer optimization problem. The design goal is to find a topology where each channel has a given cross-section area, using a minimum amount of sheet metal. In addition to a light-weight design, stiffness should also be taken into account. The entire approach is demonstrated in the design of a conduit with several separate channels.

Surrogate modeling for geometry optimization in material design. **Marielba Rojas** (Danmarks Tekniske Universitet, Denmark) IC/CT1986/015

One of the main problems in material design is the determination of the electronic structure of a given material. The first step in electronic-structure calculations is geometry optimization, i.e. finding a stable arrangement of the atoms in a molecule.

One of the most popular and successful approaches for the study of materials is density-functional theory. Under this model, the calculation of the optimal geometry involves the

minimization of the total-energy functional. The evaluation of this functional for a given geometry is a time-consuming process.

Due to the cost of evaluating the objective function, the use of standard minimization techniques is prohibitive in practice. An alternative is the Car-Parrinello method, also called indirect optimization or quantum-molecular-dynamics approach, which avoids the direct evaluation of the total-energy functional. This method can be very expensive for large molecules and is not robust in general, especially for metals.

We have recently proposed a new approach for geometry optimization based on surrogate modeling. We use both splines and kriging to construct the surrogates. We describe our approach and present preliminary results on test problems and on a diamond crystal.

Analytical-numerical methods in the curvilinear airfoils optimization of maximal or minimal drag in hydro-aerodynamics. **Mircea Lupu** (Transilvania University of Brasov, Romania) IC/CT3839/061

In this paper are solved direct and inverse boundary value problems and is obtained analytical and numerical the solution for the problem optimization, in the case of nonlinear integral operators. We considered the plane potential flow of an inviscid, incompressible and limited or unlimited fluid jet, which encounters symmetrical curvilinear obstacle; it is modeled the design in the case maximal or minimal drag. There are derived for direct and inverse problems the singular integral equations and it is obtained the movement in the auxiliary canonical half plane. Using my results of the integral equations method we obtained the analytical solution, considering a general distribution of the speed on the profile. The nonlinear operators of the drag are maximized using a Jensen type inequality. The drag coefficient and other parameters geometrical and aerodynamical are computed numerically in the special general case of Helmholtz or Rethi - Bobilev - Jacob scheme. We restart by the Newton Problem, in the case of the minimal drag problems for the same scheme and thought the inverse method it is given apriority the speed on profile in the singular equations it is determined the drag resultant minimal. We apply penalty method and we determined the profile design. These results are applied trust reversal devices, to the control of the direction of area reactive vehicle, to the design of the wings of an airplane, of the blades of a turbine or of the bracket parachute.

An iterative optimum-optimorum theory for global optimal shape design. **Adriana Nastase** (RWTH Aachen, Germany) IC/CT1989/067

IC/CTS4679/06: Miscellaneous, I.

Iterated hard shrinkage for linear inverse problems with sparsity constraints. **Dirk Lorenz** (Center for Industrial Mathematics - University of, Germany), Kristian Bredies (Universität Bremen, Germany) IC/CT1838/065

In this talk we describe an iterative algorithm for the minimization of Tikhonov type functionals which involve sparsity constraints in form of ℓ^p-penalties which have been proposed recently for the regularization of ill posed problems.

In contrast to the well-known algorithm considered by Daubechies, Defrise and De Mol, it uses hard instead of soft thresholding. This hard thresholding algorithm is based on the generalized conditional gradient method. General results on the convergence of the generalized conditional gradient method enable us to prove strong convergence of the iterates. Furthermore we are able to establish convergence rates of $\mathcal{O}(n^{-1/2})$ and $\mathcal{O}(\lambda^n)$ for $p = 1$ and $1 < p \leq 2$ respectively.

Numerical experiments on image deblurring and backwards heat condution are given and illustrate the established convergence rates.

Fuzzy linear-programming model for optimal farmlands fertilization. **Edmundo Vergara** (Universidad Nacional de Trujillo, Peru) IC/CT856/010

The use of the fuzzy logicŠs theoretic concepts has permitted in this work to make the mathematical model on fertilization in farming land, as a model of fuzzy linear programming whit fuzzy equality constrained, said the fuzzy diet model for fertilization in farming land. This model has solved using three methods, VerdegayŠs method, ZimmermannŠs method and WernersŠs method format.

Ecological management problem with changing protected area for fishery. **Vladimir Mazalov** (Karelian Research Centre of the RAS, Russian Federation) IC/CT3464/064

A dynamic game model of bioresource management problem is considered. There are two players: the center which determines a share of protected area of the lake where fishery is prohibited and the fishing farm which is harvesting in non-protected area. In traditional statement the center's strategy is the catch regulation by introduction quotas on fishing. We propose the approach where the center's strategy is the choice of optimal share of protected area for maintenance of stable population developement in the lake. We consider finite and infinite planning horizon and use the maximum principle and Hamilton-Jacobi-Bellman equation to derive the Nash equilibrium in the game.

The dual diagnosis of an aircraft command. **Octavian Grigore-Müler** (Universitatea Tehnicã Bucarest, Romania) IC/CT2716/068

As part of a programme investigating the design of new aircraft which are intended to be much more efficient and reliable in their use that those currently in service, the aeronautics and automatics engineers are studying aircraft and systems which would operate with greatly reduced stability margins and would as a result be totally dependent on computer control for the safety of a flight. So these computer systems generally used to provide active control should be required to have efficient diagnosis systems. A fuzzy dual diagnosis system for a command of a commercial airplane is presented.

Well-posedness and stability for abstract spline problems. **Enrico Miglierina** (Università dell'Insubria, Italy), Elena Molho (Università di Pavia, Italy) IC/CT4017/063

Spline functions play a fundamental role in many fields of numerical analysis and statistics and they are involved in many important applications, for instance in engineering, economics, biology and medicine.

The variational approach to interpolation techniques has been fruitfully employed to obtain existence and uniqueness results for interpolating spline functions. An abstract unifying framework for this topic is classically developed in the setting of Hilbert spaces. Here, following a more general approach, we consider the problem in the setting of reflexive spaces. The aim of this work is to study well-posedness and stability properties of the abstract spline problem.

The property of well-posedness of an optimization problem essentially requires that the minimizing sequences are well-behaved. This is a relevant feature in order to individuate those problems that can be studied through direct methods and to develop efficient numerical procedures. Here, we show that the same assumptions that usually ensure existence and uniqueness of a solution for an abstract spline problem also imply the stronger property of well-posedness.

The study of the stability properties of some special parametric families of abstract spline problems has already been developed in the literature. Here we consider sequence of parametric problems converging to the given abstract spline problem in order to study stability properties. Under natural assumptions, we obtain new some convergence results for sequences of solutions of the perturbed problems in the case of general version of the abstract spline problem. These results are refined in the special case where the admissible region is an affine set and, in particular, it is determined by a set of evaluation functionals, as in the classical interpolation problem.

Optimal operation mode for distributed cogeneration power plants. **Nadia Maïzi** (Ecole des Mines de Paris, France), Marc Bordier (École des Mines de Paris, France) IC/CT3348/015

Cogeneration systems combine electrical (or mechanical) and useful thermal energy from the same primary energy source. As the efficiency increases from 0.58 for a separate production of electricity and heat, to 0.85 for the cogeneration, they allow a considerable decrease in total fuel consumption. But beside these environmental issues, the economical viability of the cogeneration project remains the main issue for operators. It relies on many factors, among which the mode of operation of the cogeneration system. In this study, we will focus on the heat-match mode where the priority is to satisfy a heat demand. The amount of excess electricity is exported to the grid, while the lack of electricty is bought from an electricity market.

In the framework of the heat-match mode operation, we consider an operator who operates over a given designed (type of the technology, size, configuration) set of cogeneration units. The purpose of this paper is to determine the best operating mode in order to minimise the cost of operation of the whole cogeneration system. The optimisation procedure is achieved through two steps:

1. we consider a single unit and develop an explicit formulation of the optimal mode of operation, when the operator knows the heat and power demand, and the electricity price on the market;
2. we express for the overall cogeneration system the operating cost: the objective function is still convex but non differentiable. Thus, it requires an optimisation procedure based on subdifferential calculus: through namely the Moreau–Rockafellar and Duboviskii–Milyutin theorems.

Then, the result describing the best operating mode for the overall set of cogeneration units relies on the value of the marginal costs associated with each mode of operation, for each unit: optimal operation of the cogeneration power plant is achieved through an economic dispatch mode.

Level-set and adjoint-based optimization methods for inverse problems. **Frédéric Chantalat** (Université Bordeaux I, France), Charles-Henri Bruneau (Université de Bordeaux, France), Angelo Iollo (Université de Bordeaux, France) IC/CT2359/065

As a preamble for drag-reducing studies on Stokes flows, inverse obstacle problems governed by Laplace and Poisson equations have been considered. Dirichlet boundary conditions have been applied on both the top/bottom edges of the computational domain and the geometry interface, whereas Neumann boundary conditions have been used on the remaining edges. Shape optimization is handled by finite differences discretization of the continuous adjoint equations on a cartesian mesh. A level-set function ϕ defined below, sign-changing across the interface, enables the localization of the body by providing the distance of each node from its border.

$$\begin{cases} \phi(x,y) < 0 \;\; if \;\; (x,y) \in \Omega_{obstacle} \\ phi(x,y) > 0 \;\; if \;\; (x,y) \in \Omega - \Omega_{obstacle} \\ phi(x,y) = 0 \;\; if \;\; (x,y) \in \partial\Omega_{obstacle} \end{cases}$$

At each step, after determination of the shape-derivative, and alteration of the boundary, Fast-Marching methods operate a redistanciation process. Both direct and adjoint equations are solved by the GMRES algorithm thanks to a penalization method. However, an iterative procedure aiming at finding a consistent extension of the solution inside the penalized zone is added so that the gradient evaluation along the normal $\frac{\nabla\phi}{|\nabla\phi|}$, often inaccurate due to the use of this type of mesh can be significantly improved. Even though Level-Set methods prove to be quite efficient in terms of dealing with topoligical changes, such inverse problems appear to be severely ill-posed, causing gradient-based methods to fall into local minima regions. Thus, a study of the choice of the objective function has been carried out showing the relevance of a multiscale approach where large, medium, and small contributions follow one another along iterations in W-shaped cycles. Another way to make the problem more sensitive to shape variations was inspired by scanning techniques used in medical imagery. The angle from which the obstacle is observed is modified by rotating the obstacle during the optimization algorithm thanks to a fifth-order WENO scheme for transport equation. This method also has a drastic influence on speeding up convergence. The presentation emphisizes the role of such numerical tools in the previous cases along with an extension of the work on inverse Stokes' problem.

Newton methods for nonlinear inverse problems with random noise. **Frank Bauer** (Universität Linz, Austria), Thorsten Hohage (Universität Göttingen, Germany), Axel Munk (Universität Göttingen, Germany) IC/CT1038/065

The solution of nonlinear operator equations $F(a) = u$ by iterative regularization methods with deterministic noise has been studied intensively over the last decade. However, we are not aware of any convergence and convergence rate results of iterative regularization methods for nonlinear inverse problems with random noise. Moreover well-known stopping rules like Morozov's discrepancy principle do not work in this situation.

We will present a slightly modified iteratively regularized Gauss-Newton method with the Lepskij-type balancing principle as a-posteriori stopping rule.

We do not need any restrictive assumptions on the structure or the degree of nonlinearity of the operator F, but only have to require Lipschitz continuity of F' and a sufficiently strong source condition. As a result we obtain almost optimal rates of convergence over a range of Hölder smoothness classes.

Shape methods for the transmission problem with a single measurement. **Lekbir Afraites** (UTC Compiegne france) IC/CT703/061

In the present work, we consider the inverse conductivity problem of recovering inclusion with one measurement. First, we use conformal mapping techniques for determining the location of the anomaly and estimating its size. We then get a good initial guess for quasi-Newton type method and Newton method. The inverse problem is treated from the shape optimization point of view. We give a rigorous proof for the existence of the first and second order shape derivative of the state function and of shape functionals. We consider both Least Squares fitting and Kohn and Vogelius functionals. For the numerical implementation, we use a parametrization of shapes coupled with a boundary element method. We compare the results obtained by quasi-Newton and Newton. Several numerical exemples indicate the superiority of the Kohn and Vogelius functional over Least Squares fitting.

This is a joint work with Dr. Djalil Kateb.

Heat-source and boundary-condition identifications of a 2D composite material with different thermal diffusivities in multi-block grids. **Aziz Azimi** (Sharif University of Technology, Iran), Siamak Kazemzadeh Hannani (Sharif University of Technology, Iran) IC/CT895/065

Inverse Heat Conduction Problems (IHCPs) frequently require the reconstruction of the unknown heat sources and boundary conditions using the measured temperature history of the sensors located at interior domain or near to boundaries. Solution procedure of these problems consists of three parts: 1. a numerical solution of Partial Differential Equations (PDEs), 2. a definition of error and minimization or optimization of it, 3. a regularization scheme to stabilize the usually ill-conditioned discretized system obtained in the second part. The regularization of the optimization procedure is required to avoid the extreme sensitivity of the solution of this procedure to the errors in the measured data. Iterative regularization scheme is one of the most efficient and universal approaches for solution of IHCPs.

In this research, iterative regularization algorithms based on two parameter estimation techniques are developed to solve two-dimensional transient IHCPs. Those of the PDEs needed for inverse analysis are used in their strong conservation forms to resolve discontinuities such as thermal conductivity and diffusivity at the material interfaces. A structured discretization of the computational domain of each block is done using a simple algebraic grid generation method. The computational code developed for numerical solution of the PDEs considers a central Finite Difference Method (FDM) in conjunction with the block-structured grids with interface blocked/ overlapped points. An Alternative Direction Implicit (ADI) technique is used for temporal discretizations of the PDEs in Cartesian coordinates system. The parameter estimation techniques used for inverse analysis are Levenberg-Marquardt and adjoint conjugate gradient methods. The temperature histories needed for parameter estimation are delivered by noisy/non-noisy sensors located on the upper or right boundary of the domain. Two cases are considered to show the ability of the developed code, a simultaneous estimation of two time-varying heat sources and an estimation of upper time-space varying boundary condition in surfaces with different thermal diffusivities. The results of the present study are compared to those of exact heat source and temperature boundary condition.

Strong convergence of approximate proximal methods. **Lu-Chuan Ceng** (Shanghai Normal University, PR China) IC/CT4018/064

The purpose of this paper is to investigate approximate proximal algorithm and Bregman-function-based approximate proximal algorithm for solving the generalized variational inequality problem (for short, GVI(T,Ω) where T is a pseudomonotone multivalued operator). The goal for the present work is twofold. First, consider subproblems on the domains $\Omega_n \supset \Omega$, $n = 1,2,...$, which form a general approximate proximal point scheme. It is shown that this general approximate proximal point scheme generates a sequence, which converges strongly to a solution of GVI(T,Ω). Second, by virtue of a suitable Bregman function, define new approximating problems on the domains $\Omega_n \supset \Omega$, $n = 1,2,...$, which form a general Bregman-function-based approximate proximal point scheme for solving GVI(T,Ω). It is also proven that this general Bregman-function-based approximate proximal point scheme generates a sequence, which converges strongly to a solution of GVI(T,Ω).

On portfolio optimization using fuzzy decisions. **Sudradjat Supian** (Bucharest University, Romania), Vasile Preda (University of Bucharest, Romania) IC/CT3511/010

We consider stochastic optimization problems involving stochastic dominance constraints. We develop portfolio optimization model involving stochastic dominance constrains using fuzzy decisions and we concentrate on fuzzy linear programming problems with only fuzzy technological coefficients, aplication of modified subgradient method to fuzy linear programming problems.

Key words. stochastic programming, stochastic dominance, portfolio, fuzzy linear programming, optimality conditions, duality,. AMS subject classifications. Primary, 90B28, 90C15, 90C46, 90C70; Secondary, 46N10, 90B10, 91B06

Some characteristics of an investment project's efficiency. **Efim Bronshtein** (Ufa State Aviation Technical University, Russian Federation) IC/CT505/015

The investment project is a vector $C = (c_0, c_1, \check{E}, c_n)$ of arbitrary finite dimension such that its first nonzero component is negative, $c_n > 0$, $\sum c_i > 0$. Negative components mean investments to the project at the corresponding time moments (years), positive - receipts to the investor. A few characteristics are usually applied for the comparative analysis of investment projects.

One characteristic of the investment project was defined by K.Arrow and D.Levhari [1]. Let $P_k(k = 1,2,...,n)$ be the functions of profitability of the truncated investment projects, i.e.$P_k(x) = \sum_{i=0}^{k} c_i x^{-i}$, where x is a year accumulation coefficient and $\psi(x) = max_k\{P_k(x)\}$.

PROPOSITION 1. The equation $\psi(x) = 0$ has a unique root $AL(C)$ in the set $[1,\infty)$.

The class of investment projects (named correct projects) and its efficiency characteristic (named limited profitability) were defined in [2]. Let us reminde here these definitions. Transaction is the year loan $(0,...,0,-a,b,0,...)$ where $b \geq a > 0$. The investment project is correct if it can be represented as the sum of some consecutive transaction. Correctness of the project is equivalent to the validity of the following conditions: $c_0 < 0$, $\sum_{i=k}^{n} c_i \geq 0$ for $k = 0,1,...,n$. The correct project can

be differently represented as the sum of transaction.

We define a profitability of the transaction as the relation b/a. A profitability of the sum of transactions is defined as a maximal of component's profitabilities. The limited profitability $LP(C)$ of the correct project is equal to the minimal profitability of the sums of the transaction representing project C.

PROPOSITION 2. $AL(C) = LP(C)$ for the correct investment projects.

Some properties of limited profitability showing its practical advantage are established in [2].

The research is supported by the Russian Foundation for Basic Research (project 04-06-80009).

Higher-moment risk measures: application to portfolio optimization. **Pavlo Krokhmal** (University of Iowa, USA) IC/CT3529/063

In this talk we discuss modeling of risk-averse preferences in stochastic optimization problems using risk measures. In particular, we consider the axiomatically defined risk measures, such as coherent risk measures (Artzner et al, 1999), deviation measures (Rockafellar et al, 2004), etc. We utilize the axiomatic foundation of coherent risk measures and deviation measures in order to develop simple representations that express risk measures via solutions of specially constructed (convex) stochastic optimization problems, which, in turn, can be seamlessly incorporated into the objective and/or constraints of mathematical programming models. As a special case of the developed general representations, we introduce a new family of higher-moment coherent risk measures (HMCR) that quantify risk via higher tail moments of loss distributions. It is shown that the family of HMCR measures can be implemented in mathematical programming problems using p-order cone programming. To facilitate incorporation of HMCR measures into existing decision-making models (such as portfolio optimization models, etc.), polyhedral approximations of p-order conic constraints are presented. Further, it is demonstrated that the HMCR measures are compatible with second order stochastic dominance and utility theory, in the sense that minimization of risk using an HMCR measure yields a SSD-efficient solution. A portfolio optimization case study illustrates the practical merits of employing the HMCR measures in an aggressive trading setting.

On existence of exact penalty in constrained optimization . **Alexander Zaslavski** (Technion – Israel Institute of Technology) IC/CT1431/063

In this talk we discuss the penalty approach in optimization and a very simple sufficient condition for the exact penalty property.

Support-vector machine via nonlinear rescaling. **Igor Griva** (George Mason University, USA), Shen-Shyang Ho (George Mason University, USA), Roman Polyak (George Mason University, USA) IC/CT1946/063

This talk presents a support vector machine (SVM) based on the nonlinear rescaling (NR) methodology. The formulation of the linear SVM based on the NR method leads to an algorithm that reduces the number of support vectors without compromising classification performance compared to the linear soft-margin SVM formulation. The dual variables provide important information about each data point and play the key role in selecting the set of support vectors. Experimental results on ten benchmark classification problems demonstrate that the quality of discrimination of the NR-SVM is comparable to the linear soft-margin SVM while the number of support vectors is substantially reduced.

Application of LQR techniques to the adaptive control of quasilinear parabolic PDEs. **Jens Saak** (TU Chemnitz, Germany), Peter Benner (TU Chemnitz, Germany) IC/CT2481/061

LQR problems for linear parabolic PDEs have been studied in detail in the literature for the past 3 to 4 decades. The solvability of feedback control problems for a large class of problems is well understood. In the recent years numerical methods for the approximation of the corresponding Riccati operators have been developed. These methods are able to calculate the feedback operator directly and thus can compute the solutions to linear problems efficiently.

Here we study the applicability of such techniques to the control of quasilinear equations via local linearization in an adaptive control setting.

Shape and topology optimization of contact problems by level-set method. **Andrzej Myslinski** (Polish Academy of Sciences, Poland) IC/CT3088/061

This paper deals with the formulation of a necessary optimality condition and numerical solution of the topology and shape optimization problems of an elastic body in unilateral contact with a rigid foundation. The contact with a given friction, described by Coulomb law, is assumed to occur at a portion of the boundary of the body. This contact problem is described by an elliptic inequality of the second order governing a displacement field. The optimization problem consists in finding, in a contact region, such shape of the boundary of the domain occupied by the body that the normal contact stress is minimized.

Level set methods are numerically efficient and robust procedures for the tracking of interfaces, which allows domain boundary shape changes in the course of iteration. The evolution of the level set function is governed by the Hamilton – Jacobi equation. The speed vector field driving the propagation of the level set function is given by the Eulerian derivative of an appropriately defined cost functional with respect to the free boundary.

In this paper the necessary optimality condition is formulated. The holes are supposed to be filled by weak phase mimicking voids. The level set method, based on the classical shape gradient, is coupled with the bubble or topological derivative method, which is precisely designed for introducing new holes in the optimization process. Since both methods capture a shape on a fixed Eulerian mesh and rely on a notion of gradient computed through an adjoint analysis, the coupling of these two method yields an efficient algorithm. Moreover the finite element method is used as the discretization method. Numerical examples are provided and discussed.

Boundary-optimal flow control with state constraints. **Juan Carlos de los Reyes** (Escuela Politécnica Nacional, Ecuador) IC/CT858/061

The boundary optimal control problem of the Navier–Stokes in presence of pointwise state constraints is studied. After discussing the choice of adequate control spaces, a Lavrentiev regularization of the problem is introduced. The regularity of the multipliers is studied and convergence of the regularized solutions towards the original one is proved. A semi-smooth Newton method is applied for the numerical solution of each regularized problem and numerical experiments are carried out.

Numerical solution of differential Riccati equations arising in optimal control for parabolic PDEs. **Hermann Mena** (Escuela Politécnica Nacional, Ecuador), Peter Benner (TU Chemnitz, Germany) IC/CT2517/061

The numerical treatment of linear-quadratic regulator problems on finite-time horizons for parabolic partial differential equations requires the solution of large scale differential Riccati equations (DREs). Typically the coefficient matrices of the resulting DRE have a given structure (e.g. sparse, symmetric or low rank). Here we derive numerical methods for solving DREs capable of exploiting this structure, which are based on a matrix-valued implementation of the BDF methods. The crucial question of suitable stepsize and order selection strategies will also be addressed.

Path-following methods in function space for state-constrained optimal control. **Anton Schiela** (Zuse-Institut Berlin, Germany) IC/CT1905/006

Pathfollowing methods in function space are widely considered as a very promising concept for the solution of optimization problems subject to PDE constraints and bounds on the state.

There are a number of different approaches available (e.g. barrier methods, penalty methods, Lavrentiev regularization), which all share the idea of solving a sequence of regularized problems by (semi-smooth) Newton methods in order to compute successive approximations of the desired solution.

Subject of this talk are theoretical results and algorithmic ideas that contribute to the understanding and implementation of this class of methods.

Uncertainty modeling in autonomous robust spacecraft design. **Martin Fuchs** (Universität Wien, Austria), Arnold Neumaier (Universität Wien, Austria), Daniela Girimonte (European Space Agency, The Netherlands) IC/CT4747/006

In the last years, much research has been dedicated to the achievement of decisions support systems to the space system engineers or even of autonomous design methods which try to capture the reasoning of the system experts. However, the problem of taking into account the uncertainties of the variables and models towards an optimal and robust spacecraft design has not been tackled effectively yet.

Traditional modeling of uncertainties faces several problems. In current methods considering worst case analysis the ignorance of distributions of uncertain variables or the ignorance of correlations between uncertain data, respectively, sometimes leads to underestimations of error probabilities. Moreover, even provided the knowledge of the multivariate probability distributions, in higher dimensions the numerical computation of the error probabilities is very expensive, if not impossible.

The new concept of **Clouds** for handling uncertainties was introduced by Neumaier, A. in 2004. Clouds are combining the concept of a fuzzy set and that of a probability distribution. They capture useful properties of the probabilistic and fuzzy uncertainties, enabling the user to utilize the collected empirical information (even if very limited in amount) in a reliable, validated way.

For given confidence levels the clouds provide regions of relevant scenarios affecting the worst case for a given design. In robust design, a design is considered unsafe if one of the relevant scenarios does not satisfy the safety-requirements. The concept, applied to the problem of optimization of robust spacecraft system design, aims at finding the optimal design with regard to the safety constraints and to the uncertainty information provided by expert designers.

On-line state estimation for nonlinear dynamical systems. **Natalia Dmitruk** (National Academy of Sciences, Belarus) IC/CT731/062

For a wide range of real-life problems appearing e.g. in biology or chemistry the measurement of some variables of the problem are difficult or impossible. Therefore a problem of estimation of the states of a dynamical object on the base of only a few available measurements arises. There are numerous techniques for state estimation developed for specific objectives and/or type of information available.

In this presentation the focus is on a set-based estimation of the states of a dynamical system required for construction of optimal guaranteeing feedbacks. In particular, we aim at the construction of polyhedral approximations of sets of all states consistent with the obtained measurements. A problem of constructing estimates, associated with these approximations, is called an optimal observation problem. This presentation presents numerical methods for solving optimal observation problems for nonlinear dynamical systems. To tackle the nonlinearities two problems are studied: an optimal observation problem for a piecewise linear dynamical system (a piecewise linear approximation of the nonlinear problem) and a quasilinear optimal observation problem (local approximations of nonlinearities). For the piecewise linear observation problem the solution is built on the base of two procedures: linearization of the problem along a feasible trajectory and solution of the linearized problem; and correction of the obtained solution by choice of the optimal times of transition between the domains of linearity. For the quasilinear optimal observation problem an asymptotic method of constructing a suboptimal solution on the base of the optimal solution of a corresponding linear problem is proposed. The asymptotic technique combined with the method for solving piecewise linear problems is the base for a numerical procedure for constructing the state estimates of a general nonlinear system in real-time.

Structured doubling algorithms for Hermitian solutions of algebraic Riccati equations. **Tsung-Min Hwang** (National Taiwan Normal University), Wen-Wei Lin (National Tsing Hua University, Taiwan) IC/CT87/062

In this talk, we propose structured doubling algorithms for the computation of weak Hermitian solutions of continuous/discrete-time algebraic Riccati equations. Under the assumptions that partial multiplicities of purely imaginary and unimodular eigenvalues (if any) of the associated Hamiltonian and symplectic pencil, respectively, are all even, we prove that the developed structured doubling algorithms converge to the desired Hermitian solutions globally and linearly. Numerical experiments show that structured doubling algorithms perform efficiently and reliably.

Optimizing system performance in the event of feedback failure. **Debraj Chakraborty** (University of Florida, USA), Jacob Hammer (University of Florida, USA) IC/CT4764/062

Feedback is often used to overcome the adverse effects of perturbations and uncertainties on the performance of engineering systems. However, failures of the feedback channel cannot be completely avoided. The present talk addresses the questions of how and for how long can desirable performance of a perturbed system be maintained after a failure of the feedback channel. In mathematical terms, these questions translate into an optimal control problem which can be formulated as follows.

Let Σ_ϵ be a system that is subject to a perturbation ϵ in its parameters. The exact value of the perturbation ϵ is not known; it is only known that ϵ is bounded by a given constant δ. Now, let $u(t)$ be an input function of Σ, and let $\Sigma_\epsilon u$ be the response of the perturbed system to the signal $u(t)$. The nominal system is Σ_0, and the nominal response to the signal $u(t)$ is $\Sigma_0 u$. Therefore, the deviation in the response caused by the perturbation is $\|\Sigma_\epsilon u - \Sigma_0 u\|$. To reduce the perturbation, add a "correction signal" $v(t)$ to the input signal, so that the perturbed response becomes $\Sigma_\epsilon(u+v)$. Then, the new deviation between the perturbed and nominal cases becomes $\|\Sigma_\epsilon(u+v) - \Sigma_0 u\|$. The correction signal $v(t)$ must be independent of the perturbation value ϵ, as the latter is not known.

Let M be the maximal deviation allowed for the response, and let t_f be the time for which $\|\Sigma_\epsilon(u+v) - \Sigma_0 u\| \le M$. Then, the objective is to find a correction signal $v(t)$ that maximizes t_f, given only that the perturbation ϵ is bounded by δ. The talk presents Euler-Lagrange type first-order conditions for calculating the optimal correction signal $v(t)$. It is shown that, under rather broad conditions, the optimal correction signal $v(t)$ is either a bang-bang signal or can be arbitrarily closely approximated by a bang-bang signal.

An optimal control approach to nonrigid image registration. **Georg Stadler** (University of Texas at Austin, USA), Omar Ghattas (University of Texas at Austin, USA) IC/CT4584/061

Non-rigid image registration can be described briefly as follows: given so-called template and patient images, one wishes to find a reasonable transformation that makes the transformed template as similar as possible to the patient image. Image registration problems are particularly prevalent in medical image processing applications, for example registration of preoperative and intraoperative image-guided surgical plans, finding anatomical aberrations among populations of patients, tracking tumor morphology over time, and cardiac motion analysis. The problem of finding a reasonable transformation is ill-posed and is usually treated by appropriate regularization. While elastic strain energy regularization is often used, we reformulate the registration problem as an optimal control problem. This allows the choice of a regularizer that acts mainly in directions tangential to interfaces within the image. Since these directions lie in the kernel of the Hessian, the minimizer (i.e., the registered image) becomes (almost) independent of the regularization weight parameter. To solve the resulting constrained optimization problems numerically, we apply an inexact Gauss–Newton method. A multilevel approach is used to speed up the iteration and to avoid local minima. The proposed methods are numerically compared with elastic registration. We also discuss the regularity of the transformation between template and patient image, since this is of importance in most applications.

Linear semi-definite programs with log*-determinant terms.* **Mituhiro Fukuda** (Tokyo Institute of Technology, Japan) IC/CT4370/063

The new version of SDPA permits one to solve linear semidefinite programs with log determinant terms with different nonnegative weights. Such features are already included in SDPT3 and partially in MAXDET. Examples of such problems arise in robust optimization, statistics, quantum information theory, etc. Numerical experiments on test problems will be presented to test its robustness and efficiency in order to attend the demand of further applications.

Convex separable minimization with box constraints. **Stefan Stefanov** (Neofit Rilski South-Western University, Bulgaria) IC/CT379/063

Consider minimization problems with a convex separable objective function subject to a convex separable inequality constraint of the form " $\le$ " / linear equality constraint / linear inequality constraint of the form " $\ge$ ", and bounds on the variables (box constraints). Denote these three problems by $(C^{\le})$, $(C^{=})$, and $(C^{\ge})$, respectively. Problems of the considered form arise, for example, in allocation of resources, in inventory control, in scheduling theory, in facility location, in the theory of search, in implementation of projection-type methods when the feasible regions are the same as the feasible regions of the considered problems, etc. For each of problems $(C^{\le})$ and $(C^{=})$, a necessary and sufficient condition is proved for a feasible solution to be an optimal solution to the respective problem, and a sufficient condition is proved for a feasible solution to problem $(C^{\ge})$ to be an optimal solution to this problem. Algorithms of polynomial complexity for solving the three problems are proposed and convergence of these algorithms is proved. Some particular problems of the forms $(C^{\le})$, $(C^{=})$, and $(C^{\ge})$ as well as computational results are presented.

Newton and Halley are one step apart: a review of computational issues for cubically-convergent methods. **Trond Steihaug** (University of Bergen, Norway), Geir Gundersen (Universitetet i Bergen, Norway) IC/CT2219/063

In this talk we discuss the relationship betweeen Halley's and Newton's methods for unconstrained optimization. Halley's method actually is a class of methods all parameterized with a real parameter α. For unconstrained optimization, Halley's method uses second (the Hessian matrix) and third derivative (called the tensor). When the problem is large the second derivative will be sparse. We introduce the concept of *induced sparsity structure of the tensor*, induced by the structure of the Hessian matrix. We show how to utilize this structure to increase the efficiency. We compare the number of arithmetic operations of Halley's and Newton's method and illustrate the effect of utilizing the sparsity. We also give some numerical results of Halley's method.

Gutiérrez and Hernandez defined a class of methods defined by

$$x_{k+1} = x_k - \{I + \tfrac{1}{2}L(x_k)[I - \alpha L(x_k)]^{-1}\}(F'(x_k))^{-1}F(x_k), \quad k \ge 0,$$

where $L(x) = (F'(x))^{-1}F''(x)(F'(x))^{-1}F(x)$, for solving the nonlinear system of equations $F(x) = 0$.

An equivalent formulation is

$$\begin{aligned} F'(x_k)s_k^{(1)} &= -F(x_k), \\ (F'(x_k) + \alpha F''(x_k)s_k^{(1)})s_k^{(2)} &= -\tfrac{1}{2}F''(x_k)s_k^{(1)}s_k^{(1)}, \\ x_{k+1} &= x_k + s_k^{(1)} + s_k^{(2)}, \end{aligned}$$

which, for $\alpha = 1$, W. Werner observed is two steps of Newton's method applied to the second-order Taylor approximation $T(s) = 0$:

$$F(x+s) \approx T(s) \equiv F(x) + F'(x)s + \tfrac{1}{2}F''(x)ss.$$

Quasi-Newton methods with line search for stochastic optimization. **Nataša Krejić** (University of Novi Sad, Yugoslavia), Zorana Lužanin (University of Novi Sad, Yugoslavia) IC/CT824/063

We introduce a modification of quasi-Newton methods with line search used in deterministic unconstrained optimization problem to the stochastic unconstrained optimization problem. The basic idea is to use the modifications of quasi-Newton equation and line search algorithms. Practical implementation guidance and a nontrivial numerical experiments are presented.

Newton-like method for non-smooth functions with stochastic approximation. **Sanja Rapajić** (University of Novi Sad, Montenegro and Serbia) IC/CT823/064

Various methods for solving nondifferentiable problems have been developed in recent years. Most of them are based on generalized derivatives or smooth approximation of the original function. Applications of stochastic approximation algorithms to nonsmooth functions is one way to overcome difficulties arising from nonsmoothness. A Newton-like method with stochastic approximation, which is a generalization of some method for smooth functions, is proposed.

On the secant method under generalized Lipschitz conditions for the divided difference operator. **Stepan Shakhno** (Lviv National University, Ukraine) IC/CT606/015

In work[1] for investigation of Newton's method for solving nonlinear equations generalized Lipschitz conditions for the derivative operator are suggested. There instead of constant L is used some positive integrable function.

In this work we introduce for the first time the generalized Lipschitz conditions for the divided difference operator. A positive integrable function, partial case of which is a usual Lipschitz constant, is suggested. Under the given conditions the convergence of the Secant method for the solving of operator equations in Banach spaces is investigated and the uniqueness ball for the solution is obtained. As the partial case the known results for Lipschitz constants are received. The proposed approach can be applied to the investigating of iterative difference methods of higher orders of convergence[2].

An SQP multigrid solver for finite-deformation contact problems. **Oliver Sander** (Freie Universität Berlin, Germany) IC/CT1649/063

We present a new algorithm for simulating mechanical contact between two elastic bodies undergoing large deformations. The two bodies are modelled by some hyperelastic material law, and the contact conditions are discretized using a dual mortar basis. The resulting constraint nonconvex optimization problem is solved with an SQP trust-region solver using a maximum-norm trust-region. Each inner iteration is a possibly nonconvex quadratic program on a convex set bounded by half spaces. Using a suitable basis transformation of the finite element space, this set can be written as a tensor product. That way, the inner problem can be solved with a monotone multigrid method. The resulting algorithm converges globally to a first-order stationary point. Numerical experiments show multigrid complexity of the inner solver even for non-trivial examples in three space dimensions.

On multigrid optimization for dense estimation of contrast invariant optical flow. **El Mostafa Kalmoun** (Université Cadi Ayyad, Morocco) IC/CT1019/063

We consider the computation of dense optical flow between two images under possible brightness variation. The problem is formulated as a minimization of an energy functional which consists of two weighted terms. The data term is based on a geometrical approach that is invariant to contrast changes. And the regularization term involves total variation norm which preserves motion discontinuities. For fast numerical solution, we develop and compare two approaches of using multigrid in this optimization framework. The first scheme, called TN/MG incorporates a linear multigrid solver in the inner loop of the truncated newton (TN) method to get a direction of descent. The second, called MG/TN, apply directly a multigrid strategy in the outer TN loop, while a preconditioned conjugate gradient is used for the inner loop.

This Work was done in collaboration with V. Caselles and L. Garrido

Optimal trajectories which are tangent to an affine distribution. **Fernand Pelletier** (Université de Savoie, France), Mihai-Emilian Popescu (ISMMA-Bucharest, Romania) IC/CT1572/063

In this work we study the trajectories which are tangent to an affine sub-bundle in the tangent bundle of a manifold and which minimize the *total energy*. We give some characterizations of such *regular* trajectories in terms of control theory and geometrical theory. We also build some sufficient conditions of existence for such curves. These data are also elaborate on details in the context of nilpotent Lie groups. Finally, these results are applied to a problem of elastic rod's deformations.

Global optimization of truss topology with discrete bar areas. **Wolfgang Achtziger** (Universität Dortmund, Germany), Mathias Stolpe (Danmarks Tekniske Universitet, Denmark) IC/CT1904/063

The talk considers the classical problem of finding a truss design with minimal compliance subject to a given external force and a volume bound. The design variables describe the cross-sectional areas of the bars. While this problem is well-studied for continuous bar areas, we treat here the case of discrete areas. This problem is of major practical relevance if the truss must be built from pre-produced bars with given areas. As a special case, we consider the design problem for a single bar are;, i.e., a 0/1-problem.

In contrast to heuristic methods considered in other approaches, we present an algorithmic framework for the calculation of a global optimizer of the underlying large-scaled mixed integer design problem. This framework is given by a convergent branch-and-bound algorithm which is based on solving a sequence of nonconvex continuous relaxations. The main issue of the of the approach lies in the fact that the relaxed nonlinear optimization problem can be formulated as a quadratic program (QP). Here the paper generalizes and extends theory from the literature. Although the Hessian of this QP is indefinite, it is possible to circumvent non-convexity and to calculate global optimizers. Moreover, the QPs to be treated in the branch-and-bound search tree differ from each other just in the objective function. Together with a special purpose heuristic which quickly finds good feasible discrete solutions, this makes the resulting branch-and-bound method very efficient. The talk closes with several large-scale numerical examples. To the knowledge of the authors, these examples are the largest discrete topology design problems solved by means of Global Optimization.

Zero-level pricing, universal property, and CARA utility functions. **Sy-Ming Guu** (Yuan Ze University, Taiwan) IC/CT4241/063

Zero-level pricing method has been proposed to provide price information when the no-arbitrage pricing method yields a wide price interval in an incomplete market. Zero-level price usually depends on the utility function and investor's initial wealth. Luerberger showed that if investor's utility function is quadratic, then the zero-level price is universal, namely, independent of his/her initial wealth and parameters of the quadratic utility function. In this talk, we show that CRRA utility function has the universal property as well.

Interior-point methods applied to the AC active-reactive optimal power-flow problem using cartesian coordinates. **Roy Wilhelm Probst** (Universidade Estadual de Campinas, Brazil), Aurelio Oliveira (Universidade Estadual de Campinas, Brazil), Secundino Soares (Universidade Estadual de Campinas, Brazil), Adriano Thomaz (Universidade Estadual de Campinas, Brazil) IC/CT2488/063

The primal dual interior point methods are developed to the AC active and reactive optimal power flow problem. The representation of the tensions through cartesian coordinates is adopted, once the Hessian is constant and the Taylor expansion is accurate for the second order term. The advantage of working with polar coordinates, that easily model the tension magnitudes, lose importance due to the efficient treatment of inequalities proportionated by the interior point methods. Before the application of the method, the number of variables of the problem is reduced through the elimination of free dual variables. This elimination does not modify the sparse pattern of the problem. The linear system obtained can be further reduced to the dimension of twice the number of buses also with minor changes in the sparse structure of the matrices involved. Moreover, the final matrix is symmetric in structure. This feature can be exploited reducing the computational effort per iteration. Computational experiments for IEEE systems problems are presented for several starting point strategies showing the advantages of the proposed approach.

Organiser: Chuangyin Dang (City University of Hong Kong)

Lessons of distribution processes: what have we learned?. **Nijole Simeliene** (Forschungsverein Litauen, Lithuania) IC/CT579/006

Changes in social and political values have altered the economic and financial environment in which many consumers operate. The management and control of their exposure to the various types of risk have become essential to managing the financial soudness and viability. The traditional profit functions of managing corporate cash positions have become more complex. Many of investment policy developments have emerged over recent years to meet the critical needs for more sophisticated and flexible tools of asset and liability management. This study provides an optimization of distribution processes. We investigate variuos commodity bundles or currency to be distributed among the consumers. Modelling of distribution processes yields to some statements concerning profit functions. Choosing the class of functions, satisfying all reasonable looking conditions has been analyzed.

Determining the optimal production policy for the system with imperfect production . **Chuang-Chun Chiou** (Da Yeh University, Taiwan) IC/CT962/066

This paper presents an extended economic production quantity (EPQ) model with imperfect production, quality scan, rework, and backlog. In this model, a random defective rate is considered, and the production followed by a quality scanning process produces defective items. The scanning process distinguishes the repairable and scrap portion from the defective. Then, the rework starts when scanning process ends. We assume that not all of the repairable items can be reworked to meet the specified quality standard. Some defective items can be restored as normal items, other results in scrap due to repair failure, and the others can be repaired as quality in-between. In the proposed model, the relevant costs consist of the costs for defective reworking, holding, scanning, and disposing the scrap. The optimal operating policy that minimizes the total relevant cost per unit time for the proposed model under the effect of imperfect quality is derived where shortages are allowed and backlogged.

Mathematical programming in decentralized (or hierarchical) decision systems. **Semu Mitiku Kassa** (University of Addis Ababa, Ethiopia) IC/CT514/066

In business and many other practical activities decision making has changed over the last decades. From a single person (the Boss!) and a single criterion (e.g. Profit), decision environments have developed increasingly to become multi-person and multi-criteria and even multi-level (or hierarchical) situations. In organization with hierarchical (or decentralized) decision systems, the sequential and preemptive nature of the decision process makes the problem of selecting an optimum strategy and action very different from the usual operations research methods. Therefore, a multilevel programming approach is considered in modelling such problems.

A multilevel programming problem partitions control of the

decision variables among several decision makers, each acting in a sequence to maximize his/her own objective function. The general framework of the multilevel mathematical programming methods will be discussed in brief detail. Especially the solution method for three-level linear programming problem and its difficulties will be presented.

An arbitrary starting simplicial algorithm for computing an integer point of a class of polytopes. **Chuangyin Dang** (City University of Hong Kong) IC/CT4284/066

An arbitrary starting simplicial algorithm is developed for computing an integer point in a polytope given by $P = \{x \mid Ax \leq b\}$ satisfying that each row of A has at most one positive entry. The algorithm is derived from an introduction of an integer labeling rule and an application of a triangulation of the space and consists of two phases, one of which forms a variable dimension algorithm and the other a full-dimensional pivoting procedure. Starting from an arbitrary integer point in the space, the algorithm leaves the point along one of $n+1$ rays, interchanges from one phase to the other if necessary, and follows a finite simplicial path that either leads to an integer point in the polytope or proves no such point exists. Numerical results show that the algorithm is efficient.

A hybrid model for unique shortest-path routing. **Changyong Zhang** (University of Southern California, USA) IC/CT877/066

Shortest path routing protocols are the most commonly used IP routing protocols. Due to the complexity of the constraints involved, the unique shortest path routing problem has not been explicitly formulated. Existing methods solve the problem heuristically and result in local optima in general. In this talk, two complete and explicit formulations with polynomial number of constraints are first developed, with the aim of finding a global optimal solution to the MIP problem on average data instances arising from real-world application. The two formulations are mathematically equivalent. Based on the investigation of the constraint structures of the formulations, a decomposition algorithm is proposed to solve the problem. The tradeoff is further studied between the efficiency to solve the maser problem at each iteration and the convergence rate of the proposed algorithm. The problem is thereby formulated as a hybrid model by combining the advantages of both the original two models.

Globalising the pattern-search method. **Montaz Ali** (University of the Witwatersrand, South Africa) IC/CT4436/067

The Pattern Search is a direct search based local optimization method. In this research the author proposed a global optimization algorithm that combines the salient features of Pattern Search, Simulated Annealing and Multilevel Single Linkage in a single framework. Results are presented which show that the new algorithm is very efficient and robust.

06: Optimization, Posters

IC/PP1948/006: **Inverse heat-transfer problems with differential objective function.**

Presenter: Andrzej Wawrzynek (Silesian University of Technology, Gliwice„ Poland)

To search a solution of inverse heat transfer problems an objective function is usually used. The function is a sum of squares of differences between two temperatures: the temperature, which is measured in some given measuring points and the calculated one. The matter of modifications of this objective function consists in introducing of weighting coefficients for measuring points or using some additional information results from physical analysis of the investigated problem. In this paper a new approach is presented: from N measuring points we choose one point (basic measuring point). Two sets of temperature differences are created: the first one consists of differences between two temperatures - in the given and basic points; the second set is a set of the same differences of temperature but the calculated ones. Design parameters (DP) are found from the condition of existence of objective function extreme. The objective function (OF) consists of squares of differences of adequate - measured and calculated - differences from the two described sets. A new OF is called Differential Objective Function (DOF) to distinguish from the classical OF. For transient problems, in all time steps the basic temperatures are different; so the DOF could not be created by a simple change of variables. There were investigated several series of inverse hest transfer problems with simulated measures with infrared camera to compare the both objective functions. It was assumed that laboratory specimen was a cylinder of concrete. The transient problems described by 4 parameters were solved. Several kinds of measuring errors were taken into consideration. In some cases of the errors solutions with the DOFun are exact and simultaneously the OF generates solutions with large errors. Generally, the DOF for transient heat transfer problems leads to better solutions then the classical DO. For all analysed problems the sensitivity coefficient method was applied to find the minimum value of the OF.

IC/PP4715/010: **Avoiding a random barrier as long as possible.**

Presenter: Mario Lefebvre (École Polytechnique de Montréal, Canada)

Let $x(t)$ be a one-dimensional diffusion process. Suppose that $x(t)$ evolves between a reflecting boundary at $-D$, and an absorbing boundary at $+D$. We want to maximize the time spent by the controlled process in the interval $[-D, D)$, where D is a random variable, while taking the quadratic control costs into account. The optimal control is found by considering the uncontrolled process that corresponds to $x(t)$. This problem is an extension of what is known as LQG homing.

IC/PP638/010: **Control suboptimal linear systems with delay and application in halieutics.**

Presenter: Baghdadli_Dib Nabahats Adiba (University of Tlemcen Algeria)

In this paper, we present a method under optimal for the determination of optimal control of the linear systems at delay, then applied we it to halieutics, by considering a total model that the specialists generally use it in this field, then we sought to control fishing, so as to reduce the fluctuations of the capture and the effort of fishing what brings back to us to a problem of optimal control of a system to delay with a quadratic criterion, then by using the method under optimal we could solve this problem numerically.

IC/PP1406/010: A note about self-dual k-out-of-n systems.

Presenter: Maria Albina Puente (Universitat Politècnica de Catalunya, Spain)
Co-author: Francesc Carreras (Universitat Politècnica de Catalunya, Spain)
Co-author: Josep Freixas (Universitat Politècnica de Catalunya, Spain)

We consider here a class of k-out-of-n systems and study the variation of their reliability under different assumptions. It shown that a way to achieve highly reliable self-dual k-out-of-n systems consists in maintaining the reliability of the components at a level of performance above ¡.

The k-out-of-n systems consist of n components of the same kind. The system works if at least any k of its n components are operating. Particular cases of these systems are parallel and series systems, corresponding to k=1 and k=n, respectively. Applications of k-out-of-n systems can be found in the areas of target detection, communication, safety monitoring systems and, particularly, in the area of voting systems.

In this work we study the reliability of the self-dual k-out-of-n systems, when it is assumed that all components have the reliability, p. We especially focus on the variation of the system reliability under two assumptions: (i) if we slightly increase the component reliability p and (ii) if we increase the number of components of the system. We also compare the system reliability with the components reliability.

In practice, design problems can vary appreciably if we add restrictions and the design process may consider more complex system configurations. We study the case with multiple self-dual k-out-of-n systems.

IC/PP4886/061: Optimal design and optimal damping set to a hyperbolic problem.

Presenter: Faustino Maestre (Universidad de Castilla-La Mancha, Spain)

In this work we analyze a 2D optimal design problem governed by a linear damped 1D wave equation. In this problem we would like to find simultaneously the best time-dependent optimal layout of two isotropic materials and the static position of the damping set in order to minimize certain non-linear cost depending on the gradient of the state. By means of the gradient Young measures, we compute a full relaxation of the original optimal design problem (since the lack of classical solution of these non-linear optimization problems is typical). This relaxation is justified by the presence of optimal microstrutures, first-order laminates associated to the material design and the damping set. All these analytical computations are contrasted with numerical experiments.

IC/PP718/062: Guaranteed optimization of uncertain systems with application for energy security assessment.

Presenter: Natalia Balashevich (National Academy of Sciences, Belarus)
Co-author: Faina Kirillova (National Academy of Sciences, Belarus)

A control system affected by unknown but bounded disturbances is considered. The aim is to construct a feedback such that a closed system reaches a convex endpoint set in a fixed time and to provide a maximal guaranteed value of an endpoint performance index. To account available information on disturbances, the concept of closable feedback is introduced [1]. This type of feedback is defined on the base of the assumption that the system's states will be known at some future instants. The more such closure instants are used, the better guaranteed value of the objective function could be achieved. However the increase of the number of closure instants causes enormous computational efforts. So the problem is to choose the optimal positions of a fixed number of closure instants.

Before the beginning of control process optimal positions of closure instants for given bounds of disturbance are identified and optimal open-loop control is constructed. Then, in the course of control process these positions are corrected in accordance with realized system's states, values of feedback are computed and fed to the system's input. Algorithms of solving auxiliary problems and implementing a closable feedback are elaborated.

The suggested scheme is used for optimization of economic growth model subject to constraints characterizing the desired level of energy security indicators [2]. The goal is to provide sustainable development of economic system in the face of uncertainty in energy supplies and prices.

IC/PP3655/062: Optimal-control problem of some hemi-variational inclusion: convergence of Galerkin approximation.

Presenter: Andrzej Just (Technical University of Lodz, Poland)

In this paper we study the optimal control problem described by a hemivariational parabolic inclusion. We derive the existence of optimal solutions. Then we prove the convergence of optimal values for approximated control problems to the one for the original problem. Finally, we give a simple example.

IC/PP3407/063: Application of non-local optimization approaches for synthesis of multilayer optical systems.

Presenter: Svetlana Sharapova (Moscow State University, Russian Federation)

The dependence of the spectral coefficients of layered medium on its parameters (thickness and refractive index of each layer) allows one to pose the inverse problem of searching the parameters of the medium with the desired spectral characteristics, called also the problem of synthesis of optical coatings. The characteristic feature of inverse synthesis problems is that the uniqueness of the solution is not essential. Modern approaches for the design of multilayer systems generally allow sufficiently good solution to be obtained. Therefore the question becomes of constructing not just one, but a set of essentially different designs with approximately identical spectral characteristics. With this goal, two new approaches are proposed, both based on the numerical methods of non-local optimization.

The first approach is based on the random choice of an initial approximation and the consequent application of optimization methods for the searching the local extremum of the problem. The best extremum, in the sense of the criterion func-

tion, is chosen as a solution. Different local zero- and first-order optimization methods are applied and compared in effectiveness. The results showed that the zero-order methods do not provide satisfactory effectiveness, whereas first-order methods could be used to solve different problems.

In the second approach, genetic algorithms were used for the optimization of the problem. Genetic algorithms perform a class of global search methods which are patterned on the theory of evolution. They are stochastic algorithms, which search the solution space by operating not on a single solution, but on a population of candidate solutions. This approach also shows to be very effective, and some model problems arising in the synthesis of multilayer optical systems (antireflection coating and beam splitter syntheses) have been solved by means of the proposed method.

IC/PP1265/063: Distance evaluation between quadric surfaces in $\mathbb{R}^n$.

Presenter: Marina Yashina (Saint Petersburg State University, Russian Federation)
Co-author: Alexei Uteshev (Saint Petersburg State University, Russian Federation)

Given the equations of the quadrics in $\mathbb{R}^n$, namely $X^T\mathbf{A}_1X + 2B_1^TX - 1 = 0$ and $X^T\mathbf{A}_2X + 2B_2^TX - 1 = 0$, we solve the distance evaluation problem via reducing it to that of evaluation of the minimal positive root of a univariate algebraic equation. This is performed via application of the Elimination theory algorithms. For instance, for the centered surfaces one has:

Theorem. The distance between ellipsoids $X^T\mathbf{A}_1X = 1$ and $X^T\mathbf{A}_2X = 1$ equals zero iff the matrix $\mathbf{A}_1 - \mathbf{A}_2$ is not sign-definite. Otherwise, the square of the distance coincides with (in the general case minimal) positive zero of the polynomial

$$\mathcal{F}(z) = \mathcal{D}_\mu(\det(\mu\mathbf{A}_1 + (z-\mu)\mathbf{A}_2 - \mu(z-\mu)\mathbf{A}_1\mathbf{A}_2)).$$

Here $\mathcal{D}$ stands for the discriminant of the polynomial treated w.r.t. the indicated variable.

In the frame of this approach, the corresponding nearest points on the considered surfaces can be determined as well.

IC/PP553/064: A kernel function based interior-point methods to solve $P_*(k)$-linear complementary problem.

Presenter: Mohammad Reza Peyghami (K.N. Toosi University of Technology, Iran)

Kernel functions play a special role among interior-point algorithms for linear complementary problems to define a new search direction. In this paper, an interior point algorithm based on a new class of kernel functions is proposed to solve the $P_*(k)$-linear complementary problem, $k \geq 0$. Using some appealing properties of new kernel functions, we prove that the new kernel function based large-update primal-dual interior point methods for solving $P_*(k)$-linear complementary problem enjoy an $O\left(\frac{1}{q\sqrt{p}}qk\sqrt{n}\,(\log n)^{1+\frac{1}{q}}\log\frac{n}{\varepsilon}\right)$ iteration bound, where $p, q \geq 1$ are the parameters of the new class of kernel functions. In special case, for fixed $q \geq 1$ and $p = O(\log n)$, we obtain the so far best worst case theoretical complexity, namely $O\left(k\sqrt{n}\log n\log\frac{n}{\varepsilon}\right)$, for large-update primal-dual interior point methods to solve $P_*(k)$-linear complementary problem.

IC/PP1978/065: LSTRS: Matlab software for large-scale trust-region subproblems and regularization.

Presenter: Marielba Rojas (Danmarks Tekniske Universitet, Denmark)
Co-author: Sandra Santos (Universidade Estadual de Campinas, Brazil)
Co-author: Danny Sorensen (Rice University, USA)

We describe a Matlab implementation of the method LSTRS for the large-scale trust-region subproblem:

$$\min \tfrac{1}{2}x^THx + g^Tx \quad \text{subject to } \|x\|_2 \leq \Delta,$$

where H is an $n \times n$, real, large, symmetric matrix, g is an n-dimensional real vector, and Δ is a positive scalar. This problem arises in connection with the trust-region globalization strategy in optimization. A special case, namely, a least-squares problem with a norm constraint, is equivalent to Tikhonov regularization for discrete forms of ill-posed problems.

LSTRS is based on a reformulation of the trust-region subproblem as a parameterized eigenvalue problem, and consists of an iterative procedure that finds the optimal value for the parameter. The adjustment of the parameter requires the solution of a large-scale eigenvalue problem at each step. The method relies on matrix-vector products only and has low and fixed storage requirements, features that make it suitable for large-scale computations. In the Matlab implementation, the Hessian matrix of the quadratic objective function can be specified either explicitly, or in the form of a matrix-vector multiplication routine. Therefore, the implementation preserves the matrix-free nature of the method. The Matlab implementation offers several choices for the eigenvalue calculation and it also allows the users to specify their own eigensolver routine.

We present a brief description of the LSTRS method and describe the main components and features of the Matlab software. We include comparisons with state-of-the-art, large-scale techniques for the problem. We present examples of use of the software as well as results from the regularization of large-scale discrete forms of ill-posed problems.

IC/PP4872/066: Determination of shortest paths in fuzzy weighted networks.

Presenter: Pijus Kanti De (Banasthali Vidyapith, India)

Computation of shortest path play an important role in all transportation problems and also it is an archetypical problems encountered in the domain of combinatorial optimization. Shortest path problem is the most common problem among all types of optimum path problems. Fuzziness in a network can be introduced in many different ways e.g. through edge weights, edge capacities, vertex restrictions, or arc lengths etc. In this problem author has tried to review and formalize the recently developed fuzzy shortest path problems. In the present problem attempt has been made to study the shortest path in a network in which edge weights have been considered as uncertain-that means either imprecise or unknown. Triangular fuzzy numbers have been used to represents these uncertain edge weights and then defuzzification has been done by applying signed distance ranking method to calculate fuzzy shortest path. A dynamic programming recursion formula and a tabular calculation method have been used to solve this problem.

IC/PP4060/066: Quasi-independence space and greedy spaces.

Presenter: Anil Pedgaonkar (Sydenham College, Mumbai, India)

We introduce the notion of a quasiindependence space. This is a unification of the concept of matroid and polymatroid (Introduced by Jack Edmonds). The concept serves to illustrate that viewed in this angle polymatroid is the complete continuous analogue of the notion of matroid. We claim that we distinguish between two rank functions, namely set rank function (defined for ground set and it's subsets) and vector rank function. We have also introduced two definitions of quasiindependence space using independent vectors and proved equivalence of all definitions. We have used a tool called a set W which is defined by putting some conditions on W. We are able to give a unified treatment for both discrete and continuous notions. The notion clarifies many aspects of greedy algorithms in a matroid setting and also allows us to study integer polymatroids. Moreover we are soon led to the notion of greedy space or semigreedy space a continuous analogue of the notion of greedoid introduced by Lovasz. This notion is defined and some optimization results are obtained. For Matroid theory we refer to the text of D.J. Welsh, (Matroid theory) listed in the references.

We have rephrased and proved the necessary and sufficient condition for greedy algorithm in the context of quasiindependence spaces.

IC/PP4696/066: Adding an edge between two levels to a complete K-ary tree minimizing total path length.

Presenter: Kiyoshi Sawada (University of Marketing and Distribution Sciences, Japan)

This study considers addition of relation to a pyramid organization structure such that the communication of information between every member in the organization becomes the most efficient. The pyramid organization structure can be expressed as a rooted tree, if we let nodes and edges in the rooted tree correspond to members and relations between members in the organization respectively. This presentation proposes a model of adding an edge between two nodes with different depths to a complete K-ary tree $(K = 2, 3, \cdots)$ of height H $(H = 2, 3, \cdots)$. When a new edge between a node with a depth M and its descendant with a depth N is added, an optimal pair of depth $(M, N)^*$ is obtained by maximizing the total shortening path length which is the sum of shortening lengths of shortest paths between every pair of all nodes. The optimal pair of depth $(M, N)^*$ is given as follows. When $K = 2$, then $(M, N)^* = (0, 2)$ for $H = 2, 3, 4, 5$ and $(M, N)^* = (0, 4)$ for $H = 6, 7, \cdots$. When $K = 3, 4, \cdots$, then $(M, N)^* = (0, 2)$, irrespective of H.

IC/PP3403/066: Integer optimization in WDM-filter synthesis problems.

Presenter: Dmitry Sharapov (Moscow State University, Russian Federation)

From a physical point of view, any wavelength-division multiplexing (WDM) filter is a resonance structure formed by multilayer mirrors and cavities connected with spacer layers. The total number of WDM filter layers may exceed 100, but the number of design parameters is much smaller. The spectral transmittance of a WDM filter depends on the number of filter cavities, the reflectance of filter mirrors and the phase properties of filter cavities. Successful manufacturing of WDM filters is possible due to the thickness errors self compensation provided by turning point optical monitoring. This type of monitoring needs the optical thicknesses of filter layers to be multiples of a quarter-wave at the central wavelength. The reflectance of a quarter-wave mirror depends on the number of mirror layers, and the phase properties of cavities are also defined by an integer parameter. Therefore, all design parameters take only specific integer values. It is possible to design WDM filters by a direct computation of spectral characteristics for different combinations of design parameters. However, the number of possible combinations is actually too large to produce a satisfactory design. In order to obtain a good initial approximation one can use ideas from classical approaches.

The inverse problem of designing multilayer coatings lies in searching the parameter system which satisfies the desired optical specifications. The performance of a WDM filter at any stage of the design is measured by the value of a merit function. Designing WDM filters can be considered as a specific integer optimization problem, where the main design parameters are the numbers of layers of filter mirrors and the orders of spacers. Considered classical design ideas enable the designer to interactively specify a filter prototype that can be then optimized to meet all design requirements. We propose two integer optimization techniques proved to be very efficient for constructing different filter designs.

07: Discrete Mathematics, Minisymposia

IC/MP94/015: Tensegrities.

Organiser: Brigitte Servatius (Worcester Polytechnic Institute, USA)
Co-organiser: Ileana Streinu (Smith College, USA)

Tensegrities, or tensed frameworks, are objects that fit well in the domain of metric geometry and combinatorics. Questions of rigidity and stability were already asked by architectural designers like Fuller and Emmerich and also by the artist Snelson in the 1960s and 1970s. Key results and conjectures of that time are compiled in Branko Grünbaum's *Lectures in lost mathematics*. Recent mathematical progress has paved the way to new applications in the biological sciences as well as in structural engineering. This minisymposium is intended to communicate this progress to researchers in the fields of mathematics, computer science, biology, and mechanical engineering.

Symmetric tensegrities. **Robert Connelly** (Cornell University, USA) IC/MT4495/015

Tensegrities come in all kinds of shapes and forms with all kinds of applications and purposes. Often the calculations to determine their stability can difficult or unwieldy. But if it is symmetric enough, the symmetry can be used to simplify and clarify the situation. Many of the tensegrities constructed by artists are highly symmetric, and it can be shown that they are prestress stable in the sense of structural engineering.

Combinatorial conditions for the rigidity of tensegrity frameworks. **András Recski** (Budapest University of Technology and Economics, Hungary) IC/MT4197/015

A graph is called rigid in the d-dimensional space if the bar-and-joint frameworks corresponding to its generic embeddings in the d-dimensional space are rigid. Rigid graphs are just the connected ones for $d = 1$; they were characterized by Laman and Lovász–Yemini for $d = 2$, their characterization for $d > 2$ is basically open.

One can generalize this decision problem for tensegrity frameworks in two different ways. In the weak version we are given a graph and we have to decide whether there are tensegrity frameworks (with appropriate tripartition of the edge set of the graph for bars, cables and struts) which are rigid in the d-dimensional space. In case of the strong version the input consists of the graph and the tripartition and we have to decide whether there are tensegrity frameworks with this tripartition of the edge set, which are rigid in the d-dimensional space.

We give polynomial algorithms for both the weak and the strong versions for $d = 1$ (joint result with O. Shai) and for the weak version for $d = 2$. In case of $d = 2$ some partial results related to the strong version will also be presented.

Tensegrity and symmetry. **Simon Guest** (University of Cambridge, UK) IC/MT4848/015

This talk will describe the links between group representation theory and tensegrity structures. Tensegrity structures are generally non-generic: commonly they will either have some non-trivial geometric symmetry, or an affine transformation will take them to a symmetric configuration. Group representation theory is commonly used in the applied sciences, and particularly Chemistry, to study symmetric objects: here, I will describe how the ideas developed in Chemistry can be applied to the study of tensegrity structures. In particular, I will describe how the 'form-finding' problem can be simplified by using group representation theory, and will connect these ideas to Bob Connelly's catalogue of symmetric tensegrities.

IC/MP171/015: Mathematics of VLSI design.

Organiser: Jens Vygen (Universität Bonn, Germany)
Co-organiser: Juergen Koehl (International Business Machines (IBM), Germany)

VLSI design is one of the most attractive application areas of discrete mathematics. Key features are the variety of interesting and well-defined optimization problems, constantly new problems due to rapidly progressing technology, huge and exponentially growing instance sizes, and the economic relevance.

In the last decades, more and more techniques from combinatorial optimization have been applied, and challenging problems from industrial practice led to new, and sometimes deep, mathematical theory and new algorithms. Strong relationships between academia and industry enable research focus on the key challenges and enable industry to use new research results directly. Most complex chips cannot be designed anymore without this interplay.

This minisymposium will cover key mathematical achievements in almost all areas of VLSI design, from the architecture of switching networks and logic optimization problems to timing closure, clock design problems, and classical layout, including design-for-manufacturability aspects that become very important for $65\,\mathrm{nm}$ and $45\,\mathrm{nm}$ technologies.

Physical design of digital ASICs: an overview. **Matthias Ringe** (International Business Machines (IBM), Germany) IC/MT3921/015

Physical design is the process of turning a structural description of a design into geometric data that will be used for manufacturing. Compared to processors the physical design of application specific integrated circuits (ASICs) is typically more automated and provides interesting challenges. The first part of the talk will present an overview of the design steps involved including placement, timing optimization, clock tree construction, wiring, and sign-off.

A particularly interesting problem is placement since being an early design step it has high impact on all following steps. The talk will give an introduction to standard cell placement, floorplanning, and legalization.

Integrated-circuit design: mathematical techniques for dealing with variations. **Ulf Schlichtmann** (TU München, Germany) IC/MT3927/015

After decades of relentlessly shrinking the sizes of transistors and wires, today the semiconductor industry can combine billions of transistors on a single integrated circuit (IC). This achievement comes at a cost, however. As the device dimensions have decreased, the ability to accurately control these dimensions during manufacturing has decreased as well. The industry is confronted with increasing variations of parameters such as transistor dimensions, in some cases of more than 25% of their nominal value. To ensure that despite such significant variations, a high percentage of manufactured ICs will fulfill their specifications, mathematical techniques are increasingly used during the development of ICs to analyze the impact of manufacturing variations and to optimize the IC design for robustness against such variations. We will present such techniques and discuss recent research results.

Timing optimization of VLSI designs. **Stephan Held** (Universität Bonn, Germany) IC/MT3461/015

Timing optimization is one of the key problems in VLSI design. Many different methods (i.e., transistor sizing, repeater-tree construction, clock-skew scheduling, logic restructuring) are combined to meet extremely tight timing constraints. A wide spectrum of methods from combinatorial optimization as well as nonlinear programming is applied in these subproblems. Increasing instance sizes made many classical approaches inoperative due to long run-times. We introduce new algorithms for selected sub-problems which helped to reduce run-times from several days to a few hours on largest industrial instances.

Design of robust signal and clock networks. **Philipp Panitz** (Universität Hannover, Germany), Markus Olbrich (Universität Hannover, Germany), Erich Barke (Universität Hannover, Germany) IC/MT3821/015

As technology scales down into the nanometer region new design challenges emerge. Wire delays become the performance bottleneck in VLSI circuits. Copper is introduced as new wiring material because of its low sheet resistivity, hence low signal propagation delay. The main defect mechanism shifts from shorts to opens due to the different manufacturing process for copper wires. Open defects limit the functional yield. The parametric yield decreases because of timing uncertainties emerging from manufacturing variation. Clock skew variation becomes critical because it may shorten the cycle length of the critical path. The result is a logical error. The variation of signal nets has to be accounted for. Worst case considerations lead to overly pessimistic designs. Design techniques which reduce the variation of design parameters avoid over design and increase parametric yield.

Whereas tree topologies have been applied due to their minimal wire length, the application of generic routing graphs provides multiple paths to specific sinks. Multiple paths from the source to the sink of the signal increase the robustness against open defects and smoothes the effect of variation. Yield is considered a new design objective, today. New mathematical methods are applied within global routing to create routing graphs instead of routing trees. As multi-driver nets are created by link insertion into clock nets and new buffering approaches the calculation of signal propagation delays has to be enhanced to handle general networks with multiple inputs. New design techniques and required mathematical methods are the emphasis of this talk.

Generalizing Dijkstra's algorithm to speed-up VLSI routing. **Sven Peyer** (Universität Bonn, Germany), Dieter Rautenbach (TU Ilmenau, Germany), Jens Vygen (Universität Bonn, Germany) IC/MT3888/015

We generalize Dijkstra"s algorithm to compute shortest paths in huge undirected graphs with non-negative integral edge lengths. The main idea is to cover the vertex set V by l subsets and label these subsets instead of individual vertices. We apply this algorithm to 3-dimensional grid graphs in order to speed up path search in VLSI routing. Two granularities of the sets V_i will be used. In the first application we compute reduced costs for the edges of the routing graph. Here, the subsets V_i are large subgraphs of the given grid graph and we achieve a running time of $O(l \log l)$. Secondly, we apply the algorithm to the detailed path search, where V_i is a set of l intervals covering all vertices. The running time is $O((d+1)l \log l)$, where d is the length of the shortest path w.r.t the reduced costs. This enables us to find millions of exact shortest paths in a graph with billions of vertices in a few hours. Our algorithm is part of BonnRoute, a state-of-the-art routing tool which has been used for almost 20 years to route leading-edge industrial chips.

A speculative transmission scheme for scheduling-latency reduction. **Ilias Iliadis** (IBM Zurich Research Laboratory, Switzerland) IC/MT3536/015

Low latency is a critical requirement in some switching applications, specifically in parallel computer interconnection networks. The minimum latency in switches with centralized scheduling comprises two components, namely, the control-path latency and the data-path latency, which in a practical high-capacity, distributed switch implementation can be far greater than the cell duration. A new speculative transmission scheme is presented to significantly reduce the average control-path latency by allowing cells to proceed without waiting for a grant, under certain conditions. It operates in conjunction with any centralized matching algorithm to achieve a high maximum utilization. An analytical model is presented to investigate the efficiency of the speculative transmission scheme employed in a non-blocking $N \times NR$ input-queued crossbar switch with R receivers per output. Using this model, performance measures such as the mean delay and the rate of successful speculative transmissions are derived. The results demonstrate that the control-path latency can be almost entirely eliminated for loads up to 50%.

Factoring boolean functions and low readability. **Dieter Rautenbach** (TU Ilmenau, Germany) IC/MT3939/015

It is known since a long time that boolean read-once formulas can be characterized using a graph associated to their *sum of products* representation. We discuss, simplify and extend recent related results obtained by Golumbic and Mintz (Factoring logic functions using graph partitioning, ICCAD 1999) and Golumbic, Mintz and Rotics (Factoring and Recognition of Read-Once Functions using Cographs and Normality, DAC 2001).

BonnTools: mathematics for layout and timing closure of complex chips. **Jens Vygen** (Universität Bonn, Germany), Dieter Rautenbach (TU Ilmenau, Germany), Bernhard Korte (Universität Bonn, Germany) IC/MT5018/015

The BonnTools provide innovative solutions for layout and timing closure that are used for many of the most complex integrated circuits. During 20 years of cooperation between the University of Bonn and IBM, new mathematical foundations and algorithms have been developed for the need of new technologies and leading-edge designs.

IC/MP336/072: Complex networks their models and dynamics.

Organiser: Anna Lawniczak (University of Guelph, Canada)

Dynamics of data communication networks, transportation networks, epidemiological, biological, or social networks usually depend on large number of parameters and present a challenging task to study them. Understanding the dependences among parameters and dynamics are important for the prediction purposes, the design of the man-made networks, controls of their dynamics or the controls of the dynamics of naturally occurring networks. Studies of dynamics of complex networks require models development at various levels of networks abstraction, followed by application and/or development of various analytical and statistical methodologies to investigate them. The Minisymposium will review and report on recent progress on mathematical, statistical physics and statistical methodologies to study the dynamics of complex networks of various types. It will report on new results obtained in the investigation of dynamics of complex networks, i.e., synchronization, long range dependence, phase transition. It will explore interdisciplinary cross-fertilization among various application domains.

Automata network models and their applications to study complex dynamics of data-communication networks and spread of epidemics. **Anna Lawniczak** (University of Guelph, Canada) IC/MT3184/0

Dynamics of flow and congestion in data communication networks or of spread of epidemics of infectious diseases in human populations can be complex and often are not well understood. Understanding of these complex dynamics is important for their control, prediction purposes, in data communication networks for their design, or for prevention of spread of epidemics and design of vaccination strategies. In this talk we present microscopic models of automata network types to study these dynamics and we discuss how in both cases the macroscopic dynamics emerge from the microscopic interactions. Using an abstraction of the Network Layer of the ISO OSI (International Standard Organization Open Systems Interconnect) Reference Model, that we developed, we investigate packet traffic dynamics in our data network models of data communication networks of packet switching type. We explore how network connection topology and routing algorithms affect these dynamics, in particular near the phase transition point from free flow to congestion. Also, we present individually based simulation model to study spread of epidemics of SIR (susceptible-infected-removed) type, i.e. influenza epidemics, and present selected simulation results of spatio-temporal dynamics of spread of epidemics for realistic population distribution. Additionally, we explore interdisciplinary cross-fertilization between the two discussed application domains.

Critical phenomena in evolving networks. **Danuta Makowiec** (University of Gdansk, Poland) IC/MT2755/0

The Watts–Strogatz algorithm, which transfers a square lattice to a small-world network, is modified by preferential rewiring. The preference is related to a vertex degree. Evolution of the network is set as two-step: sequential preferential rewiring of edges measured by p and updating the information about the changes made. It appears that the evolving system self-organizes into stationary states. The topological transition in the graph structure is observed with respect to p. Leafy phase: a graph formed by multiple connected vertices (graph skeleton), with plenty of leaves attached to each skeleton vertex, emerges when p is small enough to pretend an asynchronous evolution. Tangling phase: a phase where edges of a graph circulate frequently among low degree vertices, occurs when p is large. Ferromagnetic transition properties will be studied in each of the evolving network's stationary state.

Double-layer dynamics and human migration after catastrophic events. **Monica-Gabriela Cojocaru** (University of Guelph, Canada) IC/MT3713/0

This talk presents a new application of double-layer dynamics theory (DLD) in modelling dynamics of human migration problems reformulated as transportation networks problems. Recent results in DLD allow for generalizing existing migration models by accounting for sudden (discontinuous) changes in migration flows as a consequence of, for example, natural disasters or catastrophic events.

Inferring topological and dynamical properties of immune, genetic and social networks and their relation to technological networks. **Pietro Lio** (University of Cambridge, UK) IC/MT2671/0

In this talk I will show results from the analysis of the dynamical properties of immune system response networks to HIV quasi species infection, risk perception and adaptiveness of social networks in epidemics spreadings and cell-cycle transcriptional networks. Then I will describe how the study of biological networks may inspire current technology in wired and wireless networks.

IC/CTS4898/07: **Networks, graphs incl. general.**

Organiser: Radu Serban (Lawrence Livermore National Laboratory, USA)

Macro-additions: a combinatoric algorithm for summations of integers. **Arnaud Lafonte** (Laboratório Nacional de Computação Científica, Brazil) IC/CT4093/010

The purpose of this article is to provide an adequate algorithm for solving the following question: "What is the total sum of all nonnegative integers that can be generated from set of n basic digits of positional number system base λ"? The answer is an algorithm that will enable us to get this sum without having to add the summands in a term-wise mode.

The article begins with the introduction of the concept of *generation-composition* of a set F onto a set G. The result of a generation-composition is a family of sets Q, whose members are strings of $1, 2, \cdots, p$ elements. The elements of set F are p combinatoric-type operators, f_1, f_2, $\cdots$, f_p. The set G is called a *generator set* or *mother-set'*. Its members are n distinct elements: a_1, $a_2, \cdots$, a_n. The elements of resulting sets Q are strings of $j, \cdots, p$ elements each. Based on foundations of set theory, number systems, combinatorics and through a strong algebraic development, the authour obtained the searched algorithm, which was denoted *algorithm of macro-additions*. It provides an easy and fast way to calculate huge sums of integers as are the ones concerning all the integers belonging to the numerical sets that are generated from an *arrangement-type* generation-composition. The algorithm was tested in several numerical examples shown in the

paper; it proved to be an strong time-saving device for those kinds of summaritions.

A theorem on macro-additions is proposed, as well as the concepts of *generator-set* (or *mother-set*), *operator-set* (or *father-set*) and *derived set* (or *son-set*). Suggestions for future search on this matter are also proposed in the paper.

Key-words: discrete mathematics, algorithm, arrangements, combinatorics, generation-composition, sets, strings.

Highly-robust error-correction by convex programming. **Paige Randall** (California Institute of Technology, USA), Emmanuel Candès (California Institute of Technology, USA) IC/CT4261/071

We discuss a stylized communication problem where one wishes to transmit a real-valued signal $x \in \mathbb{R}^n$ (a block of n pieces of information) to a remote receiver. Is it possible to transmit this information reliably when a fraction of the transmitted codeword is corrupted by arbitrary gross errors, and when, in addition, all the entries of the codeword are contaminated by smaller errors (e.g. quantization errors)?

We show that if one encodes the information as Ax where $A \in \mathbb{R}^{m\times n}$ $(m \geq n)$ is a suitable coding matrix, there are two decoding schemes that allow the recovery of the block of n pieces of information x with nearly the same accuracy as if no gross errors occur upon transmission (or equivalently as if one has an oracle supplying perfect information about the sites and amplitudes of the gross errors). Moreover, both decoding strategies are very concrete and only involve solving simple convex optimization programs, either a linear program or a second-order cone program. We complement our study with numerical simulations showing that the encoder/decoder pair performs remarkably well.

A new approach to the 15 puzzle. **Rooholah Majdodin** (Sharif University of Technology, Iran) IC/CT4482/010

In this paper we reexamine the 15 or (n^2-1) puzzle and study its characteristics and solvability by a novel method. Also we introduce an elegant algorithm to solve the puzzle when possible by bringing the tiles to their due squares in any desired order. The defenitions and theorems are as follows:

Definition (2.1) If a sequence of moves is denoted by $\mathbf{S}$, its reverse is denoted by $\mathbf{S}^{-1}$.

Lemma (2.2) If a sequence $\mathbf{S}$ of the special piece moves transforms arrangement $\mathbf{R_1}$ to arrangement $\mathbf{R_2}$, then the reverse of $\mathbf{S}$, denoted by $\mathbf{S}^{-1}$, transforms $\mathbf{R}_2$ to $\mathbf{R}_1$.

Lemma (2.3) Suppose that arrangements $\mathbf{R_1}$ and $\mathbf{R_2}$ are reachable. Then any arrangement $\mathbf{R}_3$ reachable from $\mathbf{R_2}$ is also reachable from. $\mathbf{R_1}$.

Definition (2.4) A simple problem or a simple case is a case that in both of its initial and final arrangements, the special piece is placed in the left lower corner of the checkerboard.

Theorem (2.5) If a simple case has a solution, then the sequence of the special piece moves forms a path consisting of some loops beginning and ending at the left lower corner.

Lemma (2.6) If the path of the special piece forms a loop in the checker bored, it has made an even number of moves.

Definition (2.7) A switch is a change of place of any two pieces located on two specific squares in the checkerboard. An adjacent switch is a switch of two adjacent squares. A piece switch is a change of place of two specific pieces, wherever they are.

Definition (2.8) A tri, is a move in the play ground, consisting of a two succeeding adjacent switches which are perpendicular and share a square. A proper tri is one that does not contain the lower left square of the checker board.

Theorem (2.9) If a simple case is solvable, there is a sequence of tris that transforms the start arrangement to the final arrangement.

Theorem (2.10) If a sequence of piece switches leads to an arrangement that is identical to the initial arrangement, then its length is even.

Theorem (2.11) If in a simple case, the start and final arrangements differ in an odd number of switches (not including the lower left square), it is not solvable.

Theorem (2.12) Any initial arrangement of pieces is transformable to any final arrangement, using some sequence of piece switches.

Theorem (2.13) A simple case that its initial and final arrangements differ only in a proper tri is solvable.

Theorem (2.14) A simple case that its initial and final arrangements differ only in two succeeding piece switches (not involving the special piece) is solvable.

Algorithm A This algorithms moves the special piece to transform an initial arrangement $\mathbf{R}_i$ to a final arrangement in an $m\times n$ checkerboard if possible. Sequence $\mathbf{S}$ contains the moves in order.

Acknowledgment The author wishes to thank Dr. Ebadollah S. Mahmoodian for his constructive review.

The special routes in plane graphs. **Tatiana Panyukova** (South Ural State University, Russian Federation) IC/CT4424/072

Lots of routing problems arise in definite practical situations. Let a plane undirected graph $G = (V, E)$ be the set of items of all manipulator possible trajectories. The problem is constructing of routes satisfying different restrictions. The restrictions can be classified as local and global. For local restrictions the next edge in a route is defined by the conditions set for current vertex or edge. Examples of such restrictions are straightforward paths; a route in which the next edge is defined by the given cycle order on the set of edges incident the current vertex; a route where some edges should be passed in predefined order.

Local restrictions can be represented as system of allowed transitions T_G or as system of forbidden transitions P_G. Let $P_G(v)$ be a partition of set $E_G(v)$ of edges incident to $v \in V$. Than partition system of graph G will be the system of sets $P_G := P_G(v)|v \in V(G)$. Let $p \in P_G(v)$, $e, f \in p$. Trail which does not contain transitions $e \to v \to f$ and $f \to v \to e$ we shall designate as P_G-compatible and these transitions designate as forbidden. There are lots of researches devoted to the algorithms with local restrictions on the edges order.

The example of global restriction is problem of constructing the cover with ordered enclosing. A plane graph G is a model of a cutting plan, and route covering all the edges in this graph defines the motion of a cutting tool. It is necessary that part cut off from a sheet does not claim additional cuttings. Formally this restriction requires the lack of intersection of interior facets for any initial part of the cutting tool route and the set E. It is intended to present algorithms for constructing the compatible trail-cover of minimal cardinality for an arbitrary connected graph, an algorithm for constructing an ordered enclosing cover, and software for performing these tasks.

A parallel distributed distance-2 graph-coloring algorithm. **Radu Serban** (Lawrence Livermore National Laboratory, USA), Ned Nedialkov (McMaster University, Canada) IC/CT4481/072

We present a parallel, distance-2, bipartite graph coloring algorithm for distributed memory computers. This work is motivated by the need for scalable parallel difference-quotient approximations for ODE/DAE Jacobian matrices for use with sparse direct linear solvers within implicit integrators, such as those in SUNDIALS (Suite of Nonlinear and Differential/Algebraic Equation Solvers).

Although general-purpose, the proposed method takes advantage of (but is also constrained by) its intended use for Jacobian approximations for implicit integration. Based on independent-set coloring of the vertices in the MPI communication layer, combined with one of several sequential coloring methods (such as greedy, incidence degree, saturation degree, etc.), our algorithm has the following features: (a) it colors only the V_2 vertices in the bipartite graph $G = (V_1, V_2, E)$, enough for Jacobian approximation purposes; (b) it does not require information which is hard and/or expensive to obtain (e.g. global distance-1 neighbor information); and (c) it uses the MPI communication pattern imposed by the parallel evaluation of the ODE/DAE user-provided function.

The proposed approach was tested on matrices from the University of Florida Sparse Matrix Collection, as well as on several graphs corresponding to Jacobians of semi-discretized large-scale PDEs.

On the line degree splitting graph of the complete bipartite graphs and complete graphs. **B Basavanagoud** (Karnatak University, Dharwad, India) IC/CT1123/072

In this paper,we introduce the concept of the line degree splitting graph of a graph. Also we present the characterization of line degree splitting graphs for complete bipartite graphs. Further we obtain the results of the characterization of the line degree splitting graphs for complete graphs.

IC/CTS4897/07: Networks, graphs.

Organiser: Dietmar Dorninger (TU Wien, Austria)

On characteristic polynomials of vertex- and edge-weighted molecular graphs. **Dietmar Dorninger** (TU Wien, Austria) IC/CT576/072

We consider molecular graphs whose vertices and edges are weighted by real numbers corresponding to Coulomb and resonance integrals of the underlying chemical compounds. Given a molecular graph G we derive recursive procedures to find the characteristic polynomials of graphs that are obtained from G when new vertices and edges carrying new weights are added to G or vertices and edges of G are substituted. Exploiting these recursions in case G is a cycle or path, we obtain explicit formulas for the characteristic polynomials of the compounds that arise this way and recursive formulas for compounds that have several cycles. Since the zeros of the characteristic polynomials approximately correspond to the energy values of electrons it is of interest to understand the influence of atoms that are added to a given compound or which substitute other atoms. To this end, we look for factors of the characteristic polynomials that do not depend on the weights of the newly introduced atoms and their bonds. In special cases this leads to the investigation of common divisors of Chebyshev polynomials of the first and second kind.

(Work done in collaboration with H. Länger)

On the generalized combinatorial optimization problems and their applications. **Petrica Claudiu Pop** (North University of Baia Mare, Romania) IC/CT1647/072

Classical combinatorial optimization problems can be generalized in a natural way by considering a related problem relative to a given partition of the nodes of the graph into node sets (clusters). We will present some of the most important generalized combinatorial optimization problems: the generalized minimum spanning tree problem, the generalized traveling salesman problem and the generalized assignment problem. We will describe complexity aspects, approximation results, several models based on integer programming and mixed integer programming and some techniques used for getting optimal solutions or sub-optimal solutions for these NP-hard problems. As well we will present some interesting applications of the considered combinatorial optimization problems in network design, location problems, telecommunications, energy distribution, agricultural irrigation, agent service brokering problem, etc.

On digraph strong-searching problems. **Boting Yang** (University of Regina, Canada) IC/CT3230/072

Many real-world problems can be naturally modeled by graph/digraph searching problems. Examples include: capturing intruders in a building or a road system, clearing a complex system of interconnected pipes which is contaminated by some noxious gas, and killing a computer virus in a network system. A graph/digraph searching problem is to find the minimum number of searchers required to capture the intruder hiding in the graph/digraph. In some applications, searchers may not obey the edge directions. For example, if an intruder hiding in a building with one-way locking doors (people can go out but cannot go in without a key), then the intruder must go one-way through a door (suppose that he has no keys), but the security personnel can go both ways through a door because they have the keys. This motivates us to introduce two search models on digraphs: the strong searching model and the mixed strong searching model, in which the intruder must follow the edge directions when they move along edges, but each searcher can move from tail to head or from head to tail along edges. Monotonicity is a very important issue in graph/digraph searching problems. A search strategy is monotonic if once an edge has been cleared, the intruder cannot access to this edge in the rest of the searching process. We prove the monotonicity of both searching models. This implies that in both searching models, the intruder can be captured in a linear number of steps. We show that both searching problems are NP-complete. (This work is done in collaboration with Yi Cao).

A precinct version of the Cops and Robber *game played on powers of graphs.* **Nancy Clarke** (Acadia University, Canada) IC/CT2030/072

The game of *Cops and Robber* is a pursuit game played on a reflexive graph. The cops choose vertices to occupy, and then the robber chooses a vertex. The two sides move alternately, where a move is to slide along an edge or along a loop, i.e. pass. Both sides have perfect information, and the cops win if any of the cops and the robber occupy the same vertex at the same time, after a finite number of moves. The minimum number of cops that suffice to guarantee a win on a graph G is the *copnumber* of G. The game has been considered on infinite graphs but, in this talk, we only consider finite graphs.

We consider the Cops and Robber game when the cops are restricted to moving on assigned "beats" or subgraphs, and bound the copnumbers of powers of graphs under a variety of products. In many cases, the results are shown to be asymptotically exact.

An efficient algorithm for computing permanental polynomials of graphs. **Yan Huo** (Tsinghua University, PR China) IC/CT674/072

An efficient numerical method for computing permanental polynomials of graphs is proposed. It adapts multi-entry expansion of FFT, and is parallel in nature. It is applied to fullerene-type graphs, and works for C56, while the largest fullerene computed before is C40. Extensive numerical computations show that the algorithm is fast and stable.

The work was done in collaboration with Heng Liang and Fengshan Bai.

Graph theory and applications. **Shariefuddin Pirzada** (University of Kashmir, India) IC/CT4141/072

Mathematicians are becoming increasingly aware of the significance of graph theory as it is applied to other areas of science and being widely used to solve various real-world problems. Graph theory is used in organic chemistry, solid-state physics and statistical mechanics, electrical engineering (communication networks and coding theory), computer science (algorithms and computation), optimization theory and operations research. The wide scope of these and other applications has been well-documented cf. [7, 12]. The powerful combinatorial methods found in graph theory have also been used to prove fundamental results in a variety of areas of pure mathematics. My talk, besides giving a general outlook of these facts, will include new graph theoretical proofs of FermatŠs Little theorem and the Nielson-Schreier theorem. New applications to DNA sequencing using minimum vertex covers in graphs (the SNP assembly problem) and scheduling using edge colorings and matchings in graphs (the Timetabling problem) will also be presented.

07: Discrete Mathematics, Posters

IC/PP1127/007: **On chainos ctree graph of a graph.**

Presenter: Sangeeta Bhat (KJ Somaiya College of Arts and Commerce, Mumbai, India)

In this paper, the concept of chainos ctree graph of a graph is introduced. We present the characterization of those graphs whose chainos ctree graphs are noneulerian, hamiltonian, planar, oterplanar, minimally nonouterplanar and maximal outerplanar. also, the necessary and sufficient condition for chainos ctree graphs to have crossing number one or two are established.

IC/PP2009/015: **A way to find optimal persuadable voters in a voting system.**

Presenter: Josep Freixas (Universitat Politècnica de Catalunya, Spain)
Co-author: Montserrat Pons (Universitat Politècnica de Catalunya, Spain)

Let's suppose that certain committee is going to decide, using some fixed voting rules, either to accept or to reject a proposal that affects your interests. From your perception about each voter's position, you can make an *a priori* estimation of the probability of the proposal being accepted. Wishing to increase this probability of acceptance before the votes are cast, assume further that you are able to convince (at least) one voter to improve his/her perception in favor of the proposal.

The question is: which voters should be persuaded in order to get the highest possible increase in the probability of acceptance? In other words, which are the optimal persuadable voters? To answer this question a measure of power is considered, which is useful to identify optimal persuadable voters. Three preorderings in the set of voters, based on the voting rules, are defined and they are used for finding optimal persuadable voters, even in the case that only a qualitative ranking of each voter's inclination for the proposal has been made.

The results we present allow finding optimal persuadable voters for any given simple game and for any possible distribution of voters' preferences in relation with the proposal at hand. The key idea is the introduction of three preorderings in the set of voters.

IC/PP1405/072: **A ranking for the nodes of directed graphs based on game theory.**

Presenter: Jose Miguel Gimenez (Universitat Politècnica de Catalunya, Spain)
Co-author: Rafel Amer (Universitat Politècnica de Catalunya, Spain)
Co-author: Antonio Magana (Universitat Politècnica de Catalunya, Spain)

A cooperative game is a pair (N, v), where N is a finite set of agents or players and v is the so-called characteristic function, which assigns to every group of players or coalition S a real number $v(S)$, the worth or utility that the coalition S can obtain in the situation described by the game.

A central problem of Game Theory consists of distributing the total utility by using acceptable allocation rules. The most important solution concept for cooperative games is the Shapley value, whose payoff to each player is a weighted sum of his/her marginal contributions to the coalitions. This solution verifies symmetry and efficiency –the sum of payoffs to all players agrees with the utility of N–.

In a classical cooperative game, every coalition can form. Nevertheless, a directed graph on N can model the feasible coalitions according to the sequences of nodes obtaineed by means of its oriented edges. The cooperation is only possible when the players are related by means of the directed graph. This idea directly leads to our solution concept for a game modified by a directed graph: cooperation is possible when there exists accessibility.

The introduced solution for games modified by directed graphs is an extension of the Shapley value. If a game is symmetric –the utilities only depend on the coalition size–, the Shapley value assigns a same payoff to all players. Thus, according to our introduced solution, the allocations to the players in a symmetric game only depend on the geometry imposed by the directed edges.

Each oriented network can be described by means of a directed graph. For obtaining a ranking among the nodes without a predefined game, we use a family of cooperative games: the test games. It is an exogenous procedure with respect to the oriented network. The test games are chosen among a particular type of games with the condition of symmetry.

08: Probability and Statistics, Minisymposia

IC/MP151/008: **Statistical methods in inverse problems.**

Organiser: Thorsten Hohage (Universität Göttingen, Germany)
Co-organiser: Hanna Pikkarainen (RICAM Linz, Austria)

In inverse problems, one looks for causes for a desired or observed effect. Inverse problems are usually ill-posed in the sense that the solution depends very sensitively on data noise. Therefore, regularization strategies and the study of the dependence of approximate solutions on the noise are essential issues.

Topics discussed in this minisymposium include nonlinear statistical inverse problem, choice of regularization parameters based on multi-resolution analysis, Bayesian approaches, and convergence rate analysis from a Bayesian perspective with applications to astronomy and mass spectroscopy.

Convergence rates for the Bayesian approach to linear inverse problems. **Hanna Pikkarainen** (RICAM Linz, Austria) IC/MT2657/008

Recently, the metrics of Ky Fan and Prokhorov were introduced as a tool for studying convergence in stochastic ill-posed problems. In this work, we show that the Bayesian approach to linear inverse problems can be examined in the new framework as well. We consider the finite-dimensional case where the measurements are disturbed by an additive normal noise and the prior distribution is normal. Convergence and convergence rate results are obtained when the covariance matrices are proportional to the identity matrix.

The work has been done in collaboration with Andreas Hofinger, Johann Radon Institute for Computational and Applied Mathematics, Austrian Academy of Sciences and has been supported by the Austrian National Science Foundation FWF through the project SFB F1308.

Measurements and infinite-dimensional statistical inverse theory. **Sari Lasanen** (Oulun Yliopisto, Finland) IC/MT2268/008

The most important ingredient in the statistical inverse theory is the indirect and noisy measurement of the unknown. Without the measurement, the formula for the posterior distribution becomes useless. However, insertion of the measurement to the posterior distribution is not always simple. Especially this happens when the measurement and the unknown are infinite-dimensional.

In the general setting, the posterior distribution is defined as a regular conditional probability. Hence it is known up to almost all measurements which is inconvenient when we are given a single measurement. This shortage is covered in the finite-dimensional statistical inverse theory by fixing versions of probability density functions. A usual choice is to consider continuous probability density functions. Unfortunately, infinite-dimensional probability measures lack density functions which prohibits us from using the same method in the general setting. In this presentation, other possibilities for fixing the posterior distributions are discussed, especially in the Gaussian framework.

Multi-scale selection of the stopping criterion for MLEM reconstructions in PET. **Nicolai Bissantz** (Ruhr-Universität Bochum, Germany), Axel Munk (Universität Göttingen, Germany), A Mair (University of Florida, USA) IC/MT1007/008

In this paper we present a fully data-driven selection algorithm for the stopping criterion for MLEM reconstructions in PET. The method can be generalized to various other reconstruction algorithms, and is based on a statistical analysis of the residuals between projected model and data.

To this end we test whether the residuals are consistent with the hypothesis of being solely due to Poisson noise. Moreover, our method includes a multiresolution approach, i.e. we test whether the residuals are consistent with pure Poisson noise for all possible re-binning of the data into increasing bin sizes in the detector space, and at all positions.

Technically, our method is based on the almost sure limiting behaviour of partial sums of the residuals. We determine the rate function which appears in the corresponding almost sure limit theorem for Poisson noise, and which is different from the Gaussian noise case. Finally, we present results from a Monte Carlo study which demonstrates the performance of the method.

On statistical linear inverse problems and multiresolution schemes. **Monika Meise** (Universität Duisburg-Essen, Germany) IC/MT1716/008

A multiresolution analysis of the residuals of an approximating function provides a criterion to decide whether an approximation is sufficiently close to the data or not. Using the model

$$y_i = Kf(t_i) + \varepsilon_i \qquad i = 1, \dots, n$$

where K is a linear operator and ε_i i.i.d. $\mathcal{N}(0, \sigma^2)$ it is shown how the idea can be combined with various forms of regularization to provide an adequate approximating function. One example is the minimization of the total variation which results in a function f_n with a small number of extreme values such that Kf_n gives a good approximation to the data.

IC/MP577/008: **Probabilistic numerical methods for PDEs and stochastic PDEs.**

Organiser: Wesley Petersen (ETH Zürich, Switzerland)
Co-organiser: Michael Mascagni (Florida State University, USA)

Monte Carlo methods for transport problems, turbulence, and high dimensional PDEs usually involve numerically solving a stochastic differential equation,

$$dX = b(X)dt + \sigma(X)dW(t),$$

where W is a vector of Wiener processes. Coefficients $b(X)$ and $\sigma(X)$ are the drift vector and square root of the diffusion matrix respectively; these appear in the PDE. Functionals of this process X will involve source terms and potentials, even non-linear variants. These talks will explore stochastic numerical methods for the solutions of PDEs. By enlarging the vector space for X, discretized versions of SPDEs can be similarly treated. Models for turbulence and financial systems can often be formulated in this way.

p-Sparse BEM for weakly singular integral equation with random data. **Alexey Chernov** (ETH Zürich, Switzerland), Christoph Schwab (ETH Zürich, Switzerland) IC/MT4992/008

We consider the weakly singular boundary integral equation $\mathcal{V}u = g$ on a randomly perturbed smooth closed surface $\Gamma(\omega)$ with deterministic g or on a deterministic closed surface Γ with stochastic $g(\omega)$. The aim is the computation of the moments $\mathcal{M}^k u := \mathbb{E}[\otimes_{i=1}^k u]$, $k \geq 1$, if the corresponding moments of the perturbation are known. The problem on the stochastic surface is reduced to a problem on the nominal deterministic surface Γ with the random perturbation parameter $\kappa(\omega)$. Note, that $u(\omega)$ depends nonlinearly on $\kappa(\omega)$.

Resulting formulation for the kth moment is posed in the tensor product Sobolev spaces and involve the k-fold tensor product operators $\mathcal{V}^{(k)} = \otimes_{i=1}^k \mathcal{V}$. The standard full tensor product Galerkin BEM requires $\mathcal{O}(N^k)$ unknowns for the kth moment problem, where N is the number of unknowns needed to discretize the nominal surface Γ. Based on [3], we develop the p-sparse grid Galerkin BEM to reduce the number of unknowns to $\mathcal{O}(N(\log N)^{k-1})$ (cf. [1], [2] for the wavelet approach).

A finite-element method for dilute polymers: numerical experiments and theoretical results. **Marco Picasso** (École Polytechnique Fédérale de Lausanne, Switzerland), Andrea Bonito (Univ. Maryland at College Park, USA), Philippe Clément (Universiteit Leiden, The Netherlands) IC/MT3534/008

A finite element method for solving viscoelastic flows (more precisely dilute polymer solutions) with complex free surfaces is presented. The method applies to macroscopic (deterministic) models such as Oldroyd-B, but also to mesoscopic (stochastic) models such as FENE dumbbells. Numerical results will be presented for complex free surface flows such as jet buckling or filament stretching.

Finally, existence and convergence of a stochastic finite element method will be presented for a simplifed Hookean dumbbells problem.

FE calculation of the 2-point correlation of the solution of an elliptic SPDE. **Bastian Pentenrieder** (ETH Zürich, Switzerland) IC/MT4991/008

Let (Ω, Σ, P) be a probability space. We consider the Poisson equation $-\triangle u = f$ in a domain D with Dirichlet boundary conditions and stochastic right hand side $f \in L^2(\Omega, \mathrm{d}P; H^{-1}(D))$. The aim is to determine the two-point correlation of the solution, $C_u(x,y) := \int_\Omega u(x,\omega)\, u(y,\omega) \mathrm{d}P(\omega)$, from the two-point correlation C_f of the stochastic loading.

C_f is assumed to belong to particular Sobolev spaces that are weighted w.r.t. the diagonal of the product domain $D \times D$, thus allowing to model singular behavior. For the solution of the problem, we employ an hp-FEM discretization resolving possible singularities on the diagonal. Numerical experiments will be presented showing exponential convergence w.r.t. the maximum polynomial degree.

This is joint work with Prof. Christoph Schwab.

IC/MP19/010: Environmental economics and stochastics.

Organiser: Pauline Barrieu (London School of Economics, UK)

With the increased awareness of global warming issues, biodiversity preservation and, more generally, of the notion of ecology, environmental economics has become a growing field of research.

More and more sophisticated techniques and methods, from probability in particular, are used and developed to study these questions, following partially the approach already adopted in mathematical finance some decades ago.

The focus of this mini-symposium session will be put on the use of both probabilistic and financial techniques in the study of environmental issues, such as stochastic optimal control, real option analysis, general equilibrium theory, or some particular forms of Backward Stochastic Differential Equations. The emphasis will be in particular on how these tools can help solving environmental problems and improving the overall management of the Environment.

Different topics will be presented in this mini-symposium session. They have however in common the study of the decision taking process, either using real option theory and applying it to some specific problems such as biodiversity and species protection (A. Leroux and P. Lasserre) or choice of decontamination policies (B. Sinclair-Desgagn), or an equilibrium approach for the hedging of some climate risk using contingent securities (U. Horst).

A real options approach to forest management and the protection of caribous from extinction. **Pierre Lasserre** (Université du Québec a Montréal, Canada) IC/MT1369/010

Uncertainty is a dominant feature of forestry and wildlife-management decision making. Aggravating this challenge is the irreversibility of some decisions, resulting in the loss of economic opportunities or the extinction of wildlife populations. We adapt the Real Options approach to determine the optimal time wood harvesting should be interrupted and banned in a forest used as habitat by some valuable animal species. The model is applied to the case of the woodland caribou (*Rangifer tarandus caribou*). Habitat growth is a mean-reverting stochastic process and it is believed by biologists that the caribou herd will become extinct if its habitat diminishes enough to reach some threshold value. While banning timber harvesting does not guarantee that the caribou habitat will be prevented from reaching the extinction threshold, it will reduce the probability of that event thereby increasing the probability of caribou survival. However there is a cost in banning timber harvesting and the decision to do so must optimally trade that cost against the probability of survival. The model incorporates economic, ecological and social features present in forest management decision making. The model is calibrated by applying a Monte Carlo approach based on forest data from Eastern Labrador, Canada.

A real options approach to brownfields and polluted-sites remediation. **Bernard Sinclair-Desgagné** (HEC Montreal, Canada) IC/MT1742/010

We consider the matter of managing the remediation of a particular polluted site. The contamination level of this site evolves randomly over time (with a drift) and can be represented as a stochastic process. Within a certain time horizon T, this level should reach a threshold L set by the regulator, or the manager will incur a significant fine F. The manager now contemplates two feasible remediation technologies: a flexible, cheap but uncertain one (natural remediation, say), and an irreversible, expensive but certain one (excavation and incineration, say). Using the machinery of real options, we first characterize and compute the manager's optimal strategy. Under this strategy, the manager starts with using the flexible technology and switches to the irreversible treatment if contamination remains above some (endogenous level) K after a certain (endogenous as well) time t.

Real options in biodiversity conservation. **Anke Leroux** (La Trobe University, Australia) IC/MT3994/010

The irreversible conversion of forests matters for biodiversity conservation in view of exogenous and endogenous types of risk. Natural ecological variations give rise to the former risk whereas the latter encompasses the consequences of extinction debt, which is a function of the rate of land conversion. Optimal dynamic land allocation decisions are derived numerically within a real options framework, where the value of biodiversity follows a controlled diffusion process. Economic-ecological system dynamics are analysed in the conservation and conversion zones for Costa Rica. It is found that extinction debt results in two competing forces with the mean effect increasing optimal biodiversity conservation, whereas the variance effect leads to greater conversion of land. The costs of extinction debt under optimal and non-optimal policy designs are quantified.

On the spanning property of risk bonds priced by equilibrium. **Ulrich Horst** (University of British Columbia, Canada) IC/MT611/010

We propose a method of pricing financial securities written on non-tradable underlyings such as temperature or precipitation levels. To this end, we analyze a financial market where agents are exposed to financial and non-financial risk factors. The agents hedge their financial risk in the stock market and trade a risk bond issued by an insurance company. From the issuer's point of view the bond's primary purpose is to shift insurance risks related to non-catastrophic weather events to financial markets. As such its terminal payoff and yield curve depend on an underlying climate or temperature process whose dynamics is independent of the randomness driving stock prices. We prove that if the bond's payoff function is monotone in the external risk process, it can be priced by an equilibrium approach. The equilibrium market price of climate risk and the equilibrium price process are characterized as solution of nonlinear backward stochastic differential equations. Transferring the BSDEs into PDEs, we represent the bond prices as smooth functions of the underlying risk factors.

IC/MP278/010: Applications of random matrices to physics and engineering.

Organiser: Ioana Dumitriu (University of Washington, USA)
Co-organiser: Alan Edelman (Massachusetts Institute of Technology, USA)

Random matrix theory is an area that brings together a large number of fields, from "classical" quantum physics and multivariate statistics, to "modern" wireless communications, computational biology, and numerical analysis, and to "exotic" number theory.

Though random matrix theory has been around since the late 1920s, it is in the last two decades that the number of applications has seen tremendous growth. Today, random matrix distributions have been connected to a wide variety of problems, from noise modeling in multiple-input, multiple-output channels, to the study of traffic patterns on German highways.

In addition to the availability of a large body of theory, this growth is also due to the recent increases in computational speed and memory, which have made it possible for software tools to be built and for distributions to be computed either empirically, with the help of matrix models, or theoretically, through special functions and advanced mathematical techniques. Via fast algorithms and mathematical tricks, computations that used to take days are now reduced to seconds, and, for the first time, made practical.

Our mini-symposium would consist of 3–4 presentations by top researchers who apply methods and tools from random matrix theory to the study of problems from signal processing, wireless communications, and statistical physics. Bringing together such a group of people would stimulate interest interest in random matrix theory, build new connections between fields, and spread information about the important open problems that random matrix theory might be able to provide an answer for.

Random matrices: a brief survey of theory and applications . **Ioana Dumitriu** (University of Washington, USA) IC/MT3522/010

How many fields of mathematics, physics, and engineering which make use of random matrix theory can one name?

The magnitude of the answer might surprise you. From the Riemann ζ-function to random permutations and from particle interactions in heavy nuclei to the capacity of MIMO channels, random-matrix distributions are being successfully used for modeling and/or explaining natural and technological phenomena. This talk will survey some of the fields where random matrix theory makes an impact, and discuss some of the theoretical distributions and models that are of interest.

The role of random matrices in compressed sensing. **Emmanuel Candès** (California Institute of Technology, USA) IC/MT3710/010

In the last few years, a new sampling or sensing theory has emerged which goes somewhat against the conventional wisdom and common practice in signal or image acquisition. This theory claims that it is possible to recover signals and images faithfully from what appear to be highly incomplete sets of data, i.e. from far fewer data bits than traditional methods use. This theory relies on two fundamental premises: 1) sparsity or compressibility of the object we wish to recover and 2) incoherence between the domain in which the object is sparse and that in which it is acquired.

It turns out that a convenient way to design incoherent measurements is by nonadaptive random sensing, hence the key role played by random matrices. Specifically, we wish to find matrices for which sparse vectors are 'away' from the (large) null space of the matrix or more quantitatively, which act on sparse vectors as near isometries—a property sometimes referred to as a uniform uncertainty principle in the literature. The talk will discuss the importance of this property together with some key results in compressed sensing, and show how to design random properties obeying this principle; e.g. by either randomly drawing the entries independently at random or by selecting the rows of a fixed orthogonal transformation uniformly at random. We will also show how certain special random matrices can be used effectively to speed up the computations required to recover the signal of interest from undersampled data.

β ensembles and simple scale-free graphs. **Petr Seba** (Czech Academy of Sciences, Czech Republic) IC/MT3751/010

We show that the eigenvalues of a simple quantum graph display spectral statistics that is well described by a beta ensemble. Depending on the topology of the graph one can obtain ensembles with beta<1 as well as with beta>1.

Recent results on the eigenvalues of random matrices with application to wireless communication systems. **Moe Win** (Massachusetts Institute of Technology, USA), Marco Chiani (Università di Bologna, Italy), Alberto Zanella (Consiglio Nazionale delle Ricerche, Italy) IC/MT5036/010

The increasing demand for wireless communications has generated interest in multiple antenna systems and, more recently, in multiple-input-multiple-output (MIMO) systems. Such systems can provide great advantages due to the presence of multiple rays propagation, causing the elements of the channel gain matrix to flutuate. Such channel gain matrix can be well modelled by random matrix with appropriate distribution. In particular, performance of MIMO systems depends on the distribution of the eigenvalues of hermitian matrices, whose dimensions are related to the number of transmitting and receiving antenna elements. In several practical situations, the elements of the channel matrix can be modeled as complex Gaussian random variables; this is the case, for example, when the propagation environment is characterized by Rayleigh or Rician fading. Under these conditions, the performance of the wireless communication systems is related to the distribution of the eigenvalues of Wishart matrices or general quadratic forms. In this talk, we describe the main problems in MIMO wireless communication, showing the relation with the theory of random matrices. More specifically, we present recent results on the distribution of the eigenvalues of Wishart matrices and related quadratic forms, and discuss the implications in terms of the performance of wireless communications.

IC/MP345/010: Monte-Carlo methods with spatially-structured randomness.

Organiser: Peter Kramer (Rensselaer Polytechnic Institute, USA)
Co-organiser: Karl Sabelfeld (Weierstraß-Institut Berlin, Germany)

The speakers in this session will describe recent research on computational techniques for representing and simulating physical processes in which some spatially distributed fields cannot be described precisely due to insufficient data. Due to the physical interactions between different regions, the uncertainty must generally be assumed to have spatial structure and is therefore typically modeled by a random field with a nontrivial spatial correlation structure. The talks in this session will describe several ways of representing the spatially structured random field in a computationally efficient way, and discuss applications such as simulating a flow through a porous medium with unresolved pore structure.

Comparative analysis of multiscale Gaussian random-field simulation algorithms. **Peter Kramer** (Rensselaer Polytechnic Institute, USA), Orazgeldi Kurbanmuradov (Turkmenian State University, Turkemistan), Karl Sabelfeld (Weierstraß-Institut Berlin, Germany) IC/MT3178/010

We analyze and compare the efficiency and accuracy of the Fourier-Wavelet and Randomization Methods for homogeneous random fields with multiscale resolution. Such random fields arise in numerical simulations and models for porous media and turbulent flows, as well as other disordered media. We focus on fractal Gaussian random fields with Kolmogorov-type spectra. We provide some conceptual and numerical comparison of the various cost contributions to each random field simulation method (overhead, cost per realization, cost per evaluation).

We find that when evaluating ensemble averaged quantities like the correlation and structure functions, as well as some multi-point statistical characteristics, the Randomization method can provide good accuracy with less cost than the Fourier-wavelet method. The cost of the Randomization method relative to the Fourier-wavelet method, however, appears to increase with the complexity of the random field statisics which are to be calculated accurately. Moreover, the Fourier-wavelet method has better ergodic properties, and hence becomes more efficient for the computation of spatial (rather than ensemble) averages which may be important in simulating the solutions to partial differential equations with random field coefficients.

Memory effects and ergodicity for diffusion in spatially-correlated velocity fields. **Nicolae Suciu** (Friedrich-Alexander University Erlangen-Nürnberg„ Germany), Karl Sabelfeld (Weierstraß-Institut Berlin, Germany), Calin Vamos (T. Popoviciu Institute, Romania), Constantin Andronache (Boston College, USA) IC/MT2851/010

Diffusion in space variable velocity fields shows a typical memory effect produced by correlations between initial conditions and velocity fluctuations on trajectories. Such correlations cause supplementary "memory terms" of the dispersion (mean square displacement of diffusing particles). We demonstrate that by theoretical investigations based on Itô and Fokker-Planck equations and numerical simulations as well. Strictly specking, only Fickian diffusion is free-of-memory. Nevertheless, for statistically homogeneous random fields, the ensemble average of the velocity correlation on trajectories yields a memory-free dispersion which does not depend on initial conditions. This quantity describes the enhancement of diffusion in a variety of models for transport in turbulent atmosphere, ionized plasma, or porous media. The reliability of the model for single replicates of the physical system requires some "ergodic behavior" in a large sense. We investigated this eventuality by root mean square deviations of actual dispersion from memory-free dispersion. The so defined "ergodicity range" was found to be strongly dependent on initial conditions. The increase of the ergodicity range for large supports of the initial concentration is essentially caused by memory terms. Moreover, the larger the anisotropy of the initial concentration is, the larger the memory terms of dispersion in the anisotropy direction are. This relation could be used in practice to identify the source of contamination from available measurement data.

IC/MP351/010: Stochastic modeling in microbiology and microphysics.

Organiser: Peter Kramer (Rensselaer Polytechnic Institute, USA)

The speakers in this session will describe applications of the methods of stochastic processes and nonequilibrium statistical mechanics toward the modeling and simulation of microphysical processes, particularly those occuring within biological cells. Several of the talks will explore the framework of molecular motors from mathematical, biological, and physical perspectives.

Effective transport properties for flashing ratchets using homogenization theory. **Juan Latorre** (Rensselaer Polytechnic Institute, USA), Peter Kramer (Rensselaer Polytechnic Institute, USA), Grigorios Pavliotis (Imperial College London, UK) IC/MT4270/010

We investigate the transport properties of Brownian flashing ratchet motors, which model molecular motors moving on periodic structures and extract useful work from the unbiased thermal environment by keeping them away from thermodynamic equilibrium. The approach for modeling these motors is set in the context of Brownian motors, since the interactions of the motor with the aqueous environment must be taken into account. For enzymes such as kinesin, the strength of thermal and damping forcing overtake the inertial terms, thus the dynamics of the motor are reduced to an overdamped equation. The interactions of the motor with the thermal environment are incorporated in the system through additive white noise, while the external driving is modeled as a multiplicative stochastic noise. We use homogenization theory to develop rigorous computations for the long time limit features of the motor, given by the effective drift and diffusivity, which may be calculated by solving cell problems (homogenized equations.) We analyze the dependence of the transport properties with respect to the parameters of the system and, ultimately, the efficiency of the motor, characterized by the Peclét number. For the case in which the motor is driven by a piecewise periodic linear potential and the system is kept far from equilibrium through a discrete state multiplicative Markov chain, we are able to solve the cell problem analytically up to a set of constants. When the external multiplicative noise is replaced by Gaussian noise, we study the solution of the cell problem both asymptotically and numerically. We compare our analytic findings and numerical solutions of the homogenized equations with Monte Carlo simulations.

Motor potential profile and a method for reconstructing it from data. **Hongyun Wang** (UC Santa Cruz, USA) IC/MT3716/010

We study molecular motors in the framework of coupled Fokker-Planck equations. The motor's motion is modeled explicitly as a stochastic continuous motion driven by a potential that changes with the chemical occupancy state. Therefore, the motor operation is specified by a set of potentials, each corresponding to one chemical occupancy state, and by the transition rates among these states. Based on the current experimental data, it is still unrealistic to determine all these potentials and transition rates. Here we propose a single potential by averaging over all chemical states and use it to characterize the motor operation. The most important advantage of working with this single potential is that it can be reconstructed from measured time series of motor positions in single molecule experiments.

Chiral separation in microflows. **Marcin Kostur** (Universität Augsburg, Germany) IC/MT3300/010

Molecules that only differ by their chirality, so called enantiomers, often possess different properties with respect to their biological function. Therefore, the separation of enantiomers presents a prominent challenge in molecular biology and belongs to the "Holy Grail" of organic chemistry. In this talk a new separation technique for chiral molecules that is based on the transport properties in a microfluidic flow with spatially variable vorticity will be presented. Because of their size the thermal fluctuating motion of the molecules must be taken into account. These fluctuations play a decisive role in the proposed separation mechanism.

Fusion versus endocytosis: the stochastic entry of enveloped viruses. **Tom Chou** (UC Los Angeles, USA) IC/MT3199/010

Viral infection requires the binding of receptors on the target cell membrane to glycoproteins, or *spikes*, on the virus membrane. Fusion peptides that make up part of these spikes on the viral membrane may then be triggered by pH changes or binding of additional coreceptors. Thus, binding of virus envelope proteins to cell surface receptors not only initiates the viral adhesion and the wrapping process necessary for internalization, but also starts the direct fusion process. Both fusion and internalization may be viable pathways for some viruses, under appropriate conditions. We develop a stochastic model for viral entry that incorporates both receptor mediated fusion and endocytosis. The relative probabilities of fusion and endocytosis of a virus particle initially nonspecifically adsorbed on the host cell membrane are computed as functions of receptor concentration, binding strength, and number of spikes. We find the parameter regimes where each pathway is expected to arise and discuss possible experimental tuning of these parameters.

IC/MP352/010: Effective stochastic modeling of multiscale systems.

Organiser: Peter Kramer (Rensselaer Polytechnic Institute, USA)

The speakers in this session will describe recent research on a variety of approaches toward representing high dimensional dynamical systems with a wide range of time scales in terms of reduced effective equations with stochastic terms. The talks will discuss both mathematical aspects of these procedures and the means by which the coefficients of the reduced equations can be computed numerically in practice.

Parameter estimation for multiscale diffusions. **Andrew Stuart** (University of Warwick, UK) IC/MT1535/010

I will describe recent work aimed at the problem of identifying effective homogenized or averaged diffusions (SDEs) from multiscale time series data.

Diffusive transport in periodic structures: underdamped dynamics. **Grigorios Pavliotis** (Imperial College London, UK) IC/MT3764/010

We study the Langevin dynamics of a Hamiltonian system with periodic potential which is subject to dissipation and is forced by white noise. We are interested in analyzing the long time asymptotics of this system as a function of the friction coefficient γ at a fixed temperature T. It is well known that under the standard diffusive rescaling the particle position converges in distribution to a Brownian motion with covariance matrix D. We study the dependence of D on γ, in particular for $\gamma \ll 1$. Furthermore we show that under an appropriate space–time rescaling, the particle position converges in distribution to a Brownian motion in the limit as $\gamma \to 0$.

Time-series analysis in multiple dimensions: dimension reduction, model fitting and prediction. **Illia Horenko** (Freie Universität Berlin, Germany) IC/MT1536/010

Due to the development of computational and measuring facilities in biology and in geo-sciences, large amounts of measured and simulated information from all kinds of processes were accumulated. All of these complex processes share the following properties:

- they are multi-dimensional, i. e. they can be completely described and understood only from the observation or measurement of many of their characteristics simultaneously,
- the dynamics of the system is typically non-linear and non-equilibrium,
- many complex systems exhibit (hidden) phases or regimes which are persistent over the long periods of time but are not (asymptotically) stable.

Several newly developed *data-based methods* for simultaneous dimension reduction, clustering and fitting of the SDE models for the analyzed multidimensional data will be presented and illustrated with some examples from molecular dynamics, climate and finance.

Stochastic modelling of spatially-distributed systems. **Radek Erban** (University of Oxford, UK) IC/MT3631/010

Many cellular and subcellular biological processes can be described in terms of diffusing and chemically reacting species (e.g. enzymes). Such reaction-diffusion processes can be mathematically modelled using either deterministic partial differential equations or stochastic simulation algorithms. The latter provide a more detailed and precise picture, and several stochastic simulation algorithms have been proposed in recent years. Such models typically give the same description of the reaction-diffusion processes far from the boundary of the simulated domain, but the behaviour close to a reactive boundary (e.g. a membrane with receptors) is model-dependent. In this talk, we show the correct choice of the boundary conditions for different stochastic models. We also show how approximate macroscopic mean-field equations can be used to improve the convergence of equation-free coarse-grained methods for the stochastic spatially distributed systems (e.g. for the stochastic reaction-diffusion processes).

IC/MP351/010: Stochastic modeling in microbiology and microphysics. #2

Organiser: Peter Kramer (Rensselaer Polytechnic Institute, USA)

(For abstract, see session #1 above.)

Collective coordinates and the mechanism for conformational transitions of complex molecules. **Tomohiro Yanao** (Kyoto University, Japan), Wang Koon (California Institute of Technology, USA), Jerrold Marsden (California Institute of Technology, USA), Yannis Kevrekidis (Princeton University, USA) IC/MT3699/010

Conformational transitions of polyatomic molecules, clusters and biopolymers are of great interest in current chemical and biological physics. Since this kind of collective motion involves many internal degrees of freedom coherently, reduction of the dimensionality is crucial for the deep understanding of their mechanisms. In this talk, we will first describe the conformational dynamics of an N-atom molecule by the three gyration radii and the (3N-9) hyperangular variables based on the framework of geometric mechanics and the hyperspherical coordinates. The three gyration radii generally serve as slow collective variables, while the remaining hyperangular variables serve as rapidly oscillating bath modes. The averaged equations of motion for the three gyration radii reveal that these collective variables are subject to two different kinds of competitive forces: One is the ordinary potential force, and the other is a kinematic force called internal centrifugal force. The potential force generally works to keep the mass distribution of the system compact and symmetric, while the internal centrifugal force works to distort and inflate it. Thus the internal centrifugal force critically initiates the large-amplitude conformational transitions of molecules. We will quantify the competition between the potential force and the internal centrifugal force by introducing an effective energy in the three-dimensional space of gyration radii, and explain the structural preference of the system between symmetric and asymmetric conformations. The present method should be useful for the systematic reduction of dimension as well as for the identification of dynamical barriers for a wide class of molecular reactions.

Optimal prediction in classical molecular dynamics. **Carsten Hartmann** (Freie Universität Berlin, Germany) IC/MT1560/010

Computer simulations of dynamical systems are a major tool for understanding certain chemical and biological processes on the molecular level. From a statistical mechanics point of view these molecular processes are responsible for the thermodynamical properties of the system. Hence a crucial point in molecular dynamics is the sound causal explanation of observable macroscopic properties in terms of the dynamics of a single molecule and in terms of dimension-reduced models. This talk addresses model reduction for mechanical molecular models from the viewpoint of projection operator techniques and optimal prediction. Given a suitable reaction coordinate, we derive a simple expression for the optimal prediction Hamiltonian, which is non-separable and contains an effective potential which, surprisingly, is not the standard free energy. The effective Hamiltonian allows for a lucid physical interpretation as a mechanical system with a curved configuration space. We illustrate that optimal prediction performs remarkably well, when it is applied to molecular dynamics problems that are intrinsically non-deterministic (e.g., conformation dynamics). It turns out that the intrinsic geometry of the reaction coordinate can have significant dynamical effects on the conformation dynamics that compete with the effects induced by the potential energy.

Stochastic dynamics of rigid bodies in application to DNA base(-pair) sequences. **John Maddocks** (École Polytechnique Fédérale de Lausanne, Switzerland) IC/MT2326/010

A basic issue for rigid base(-pair) models of DNA is the extraction of a complete set of sequence-dependent energy parameters from MD simulations. Explicit formulas are obtained in terms of equilibrium averages in the statistical mechanics sense. In the talk we consider the construction of (stochastic) dynamical systems of interacting rigid bodies in thermal equilibrium with a heat bath allowing for sampling of the canonical ensemble by means of long-term simulation. The first approach is stochastic Langevin dynamics that can be regarded as a mechanical system with additional friction and noise. As a second model for the interacting body-system we introduce the Smoluchowski equation that is derived from the Langevin

system by considering the friction limit $\gamma \to \infty$. It is restricted to configuration space and is ergodic wrt. the Boltzmann measure scaled by a metric factor going back to the rotational dynamics.

IC/MP352/010: Effective stochastic modeling of multiscale systems. #2

Organiser: Peter Kramer (Rensselaer Polytechnic Institute, USA)

(For abstract, see session #1 above.)

Stochastic mode-reduction in large deterministic systems. **Ilya Timofeyev** (University of Houston, USA) IC/MT3212/010

A new stochastic mode-elimination procedure is introduced for a class of deterministic systems. Under assumptions of mixing and ergodicity, the procedure gives closed-form stochastic models for the slow variables in the limit of infinite separation of time-scales. We show that under these assumptions the ad-hoc modification of the nonlinear self-interactions of the fast degrees of freedom can be avoided. The procedure is applied to the Truncated Burgers-Hopf (TBH) system as a test case where the separation of timescale is only approximate. It is shown that the stochastic models reproduce exactly the statistical behavior of the slow modes in TBH when the fast modes are artificially accelerated to enforce the separation of timescales. It is shown that this operation of acceleration only has a moderate impact on the bulk statistical properties of the slow modes in TBH. As a result, the stochastic models are sound for the original TBH system.

Averaging for diffusive fast–slow systems with metastability in the fast variables. **Jessika Walter** (École Polytechnique Fédérale de Lausanne, Switzerland) IC/MT2328/010

In complex system modeling one often finds mathematical models that consist of many differential equations with different temporal and spatial scales. One of the basic approaches to the complexity reduction is based on elimination of fast degrees of freedom (DOF) from the original equation by averaging according to the equilibrium probability measure corresponding to the exploration of the accessible fast state space. In this talk we consider different scenarios where the system exhibits metastability in the fast variables. To this end, we switch attention to the formal analysis of the associated Fokker-Planck equation in the asymptotic limit $\epsilon \to 0$ of infinitely fast variables, and reconsider the derivation of the effective slow (essential) dynamics over order unity time scale. Separating the time scale over which the slow dynamics proceed and the time scale of the metastable transitions will enable us to obtain a categorization of the various kinds of long-time effective behaviour that can emerge from the original system.

IC/MP180/010: Multiscale models and methods for inference.

Organiser: Sofia Olhede (Imperial College London, UK)

Observed data sets in many areas of application, such as oceanography, climatology, and medical imaging, are often non-stationary. This makes the development of non-stationary stochastic models and inferential procedures very important. Given the local and structured form of many physical processes, methods that treat the data distinctly at given scales, simplify both the modelling and analysis of such data sets. This session will synthesise recent results in the development of statistical multiscale models, inferential methods and their application. Examples of prediction, clustering and estimation methods based on using multiscale techniques will be presented, as well as innovative uses of such methods for given applications, where a physical interpretation of the multiscale structure can be made. Both 1-D and higher dimension data sets will be considered, and the numerical aspects of the implementation will be discussed, as well as analysis methods suitable for irregularly sampled data sets. The session will thus present examples to illustrate the power and flexibility of recently proposed multiscale statistical methods, and will draw together parallel and complimentary innovations, both to connect and highlight existing state of the art methods, but also to encourage future applications and development of theory and methods.

Multiscale methods and sparsity for inference. **Sofia Olhede** (Imperial College London, UK) IC/MT2804/010

Recent advances in the modelling and analysis of structured data have been developed to match the ever more difficult challenges of the 'information age' we currently inhabit. A deluge of data is routine collected in many application areas, such as medical imaging or finance, that is produced by very complicated generating mechanisms. To tackle such problems modern inferential procedures use sparsity and multiscale features of data, and build on highly sophisticated recent advances in optimisation and statistics. The methods formally treat inferential problems such as clustering, prediction and estimation, using the posited structure of the data, to in some cases even resolve problems that were otherwise not tractable.

This talk will provide an overview of new developments in the area of multiscale and sparsity based methods for inference. Methods from compressed sensing, second generation multiscale analysis, and other recently proposed frameworks for treating structured data, will be touched upon. We aim to connect and contrast novel models and methods to those already in the literature, i.e. the evolutionary spectrum and the Cramer representation of a process. We shall discuss results in generality, providing a road map for the session, as well as touch upon successful application areas.

As an example, we shall use a new multiscale multi-variate model corresponding to constraining the replication of structure across the elements of a vector-valued time series. The model allows for the estimation of both shared and individual variable structure, despite being non-stationary. To show the power of such methods we apply them to data sets collected from Oceanography.

This work was done in collaboration with Dr Jonathan Lilly, Earth and Space Resources, Washington, Seattle.

A multiscale approach for statistical characterization of functional images. **Rainer von Sachs** (Université catholique de Louvain, Belgium) IC/MT2621/010

In this paper we use an approach of spatial multiscales for an improved characterization of functional pixel intensities of images. Examples are numerous such as temporal dependence of brain response intensities measured by fMRI or frequency dependence of NMR spectra measured at each pixel. The overall goal is to improve the misclassification rate in clustering (unsupervised learning) of the functional image content into a finite but unknown number of classes. Hereby we adopt a non-parametric point of view to reduce the functional dimensionality of the observed pixel intensities, modelled to be of a very general functional form, by a combination of "aggregation" and truncation techniques. Clustering is applied via an EM-algorithm for estimating a Gaussian mixture model in the domain of the discrete wavelet transform of the pixel intensity curves. We show improvements of our multiscale method, based on complexity-penalised likelihood estimation for Recursive Dyadic Partitioning of the image, over existing monoscale approaches, by simulated and real data examples, and we give some theoretical treatment of the resulting misclassification rate in the simplified set-up of the "horizon" model of two classes. This is joint work with J. Bigot (Toulouse) and A. Antoniadis (Grenoble).

Wavelet smoothing by ℓ_ν penalized likelihood for adaptive sparsity. **Sylvain Sardy** (École Polytechnique Fédérale de Lausanne, Switzerland) IC/MT403/010

For the problem of estimating possibly sparse sequences, we derive an information criterion based on the sparsity and asymptotic properties of likelihood estimators constrained in an ℓ_ν-ball, a natural measure of sparsity for $\nu \in [0,1]$. The ability of choosing ν adaptively allows for adaptive sparsity. Applying the ℓ_ν-ball model and estimation independently to each wavelet scale leads to a wavelet smoother that has comparable predictive performances to EBayesThresh.

Change-point oriented multiscale analysis using the lifting scheme. **Maarten Jansen** (Katholieke Universiteit Leuven, Belgium) IC/MT982/010

Recent developments in multiscale analysis include non-linear and adaptive data decompositions. One possible tool in the construction of data-adaptive multiresolution transforms is the lifting scheme. In the first instance, the lifting scheme decomposes the successive steps of a wavelet transform into smaller, immedidately invertible substeps. As the substeps are immediatly invertible, it is fairly easy to explore nonlinear and adaptive alternatives. We present a decomposition where the details at given scale not only carry information on feautures at that scale, but also directional information of where to look for features at forthcoming, finer scales. This is realized by adding a directional interpretation to the detail (say, wavelet) coefficients. Instead of simply adding a linear combination of a refinement basis (the wavelet basis) to the current approximation, the refinement now takes place in a direction perpendicular on the current approximating curve. It can be verified that this strategy localizes sharp transitions in the data. The resulting *normal offset* decomposition is highly non-linear and edge-adaptive. Due to this non-linearity, the decomposition must proceed from coarse scales to fine ones (whereas the wavelet transform itself proceeds the other way around). Moreover, it is important that the transform is numerically stable. Without numerical stability, the reconstruction from modified coefficients (e.g., thresholded coefficients in noise reduction) is not guaranteed to be close to the input data. The combination of numerical stability and the coarse-to-scale nature of the decomposition limits the degrees of freedom for the transform. We discuss what sort of wavelet transforms can be extended into non-linear normal offset transforms. We then illustrate the sharp edge reconstruction in an example of noise reduction.

IC/MP180/010: Multiscale models and methods for inference. #2

Organiser: Sofia Olhede (Imperial College London, UK)

(For abstract, see session #1 above.)

A wavelet/lifting scheme based imputation method. **Tim Heaton** (University of Oxford, UK), Bernard Silverman (University of Oxford, UK) IC/CT4415/010

It is often the case when performing a spatial survey that there exist sites of interest for which the underlying function is unobserved. In this talk we develop a new method to impute the value at these sites given information from neighbouring observed sites. Our approach takes advantage of the typically sparse representation of the underlying function in the wavelet domain within a Gibbs sampler framework. We illustrate our method on both regularly spaced one-dimensional data with the classical wavelet transform as well as irregularly spaced two-dimensional data using a Voronoi based lifting scheme. In particular we consider the estimation of rainfall in the US where we compare performance of our wavelet technique to the now standard approaches of thin plate splines and kriging.

Wavelet estimation of linear regression models. **Marina Vannucci** (Texas A&M University, USA) IC/MT2590/010

This talk will consider linear regression models where the error term is long memory. Data from long memory processes have the distinctive feature that the correlation between distant observations is not negligible. Wavelets, being self-similar, have a strong connection to long memory processes and have proven to be a powerful tool for the analysis and synthesis of data from such processes. Here, in particular, we will employ discrete wavelet transforms to simplify the dense variance-covariance matrix of the error structure. We will assume general Gaussian ARFIMA(p,d,q), autoregressive fractionally integrated moving average models, for the error term. We will allow unknown autoregressive and moving average parameters. Efficient recursive algorithms will help us to compute the variances of the wavelet coefficients. These will depend on the unknown characteristic parameters of the model. Markov chain Monte Carlo methods and direct numerical integration for inference will be designed. We will also consider alternative estimation techniques based on EM methods. Performances will be initially evaluated on simulated data. Linear regression models with long memory errors have proven useful for applications in many areas, such as medical imaging, signal processing, and econometrics. Recent successful applications include fMRI image data, and in this talk we will consider experimental data from human cognitive tasks.

The wavelet-Fisz transform. **Guy Nason** (University of Bristol, UK) IC/MT1793/010

The Haar-Fisz transform has been recently introduced as a technique for variance stabilization and 'Gaussianization' for various kinds of data. For example, for Poisson sequences one can effectively stabilize and normalize by taking the Haar wavelet transform and then dividing the wavelet coefficients by a function of the father wavelet coefficients (the Fisz transform) and then inverting. The idea can be extended to many situations such as spectrum estimation and also to where the distribution is not known but key information concerning the mean-variance function of the data can be estimated (the 'data-driven' Haar-Fisz transform). This talk will focus on a mathematical assessment of the wavelet-Fisz transform and to begin to explain why it works well for several interesting problems.

IC/MP444/010: Numerical solutions of Markov chains: techniques and applications.

Organiser: Evgenia Smirni (College of William and Mary, USA)
Co-organiser: Andreas Stathopoulos (College of William and Mary, USA)

Markov chains persist as the modeling tool of choice in a host of application areas ranging from performance evaluation of computer and communications systems to areas such as software verification and search engines. Despite tremendous advances in the techniques for solving Markov chains, the problems encountered in this area continue unabated. There are three reasons for this: The first is the state space explosion; adding small complexity to a system often increases exponentially the number of possible states to be described with a Markov chain. The second reason is that better numerical techniques and increasing computing power have allowed a more accurate modeling of various systems, for which lower quality approximations were acceptable until recently. The third reason is that the same computing power can be used to solve the simplified models on-line, making intelligent resource allocation decisions when these are needed.

To overcome these scalability and efficiency problems, researchers have developed ingenious algorithms and data structures, more efficient and robust numerical methods, and often new theories that attempt to avoid numerical solutions through appropriate statistical arguments. In this minisymposium, we bring together researchers that represent the state-of-the-art in both applications and methods areas. Three researchers will talk about data-structures and fitting techniques that attempt to curb the state explosion problem, and how this finds interesting applications in software verification. Statistical arguments will also be used to present closed form solutions in the context of QBDs. Efficient solution of continuous time Markov chains will be covered, as well as computing transient measures. A fluid queue approach will be presented, which is important in modeling network traffic. Talks about methods and their numerical properties will complement this minisymposium.

Shift techniques for the numerical solution of Markov chains. **Beatrice Meini** (Università di Pisa, Italy) IC/MT1402/010

Discrete-time Markov chains are characterized by stochastic matrices; i.e, non-negative matrices such that $Pe = e$, where e is the vector of all ones. The shift technique applied to a stochastic matrix P consists in performing a rank-one modification to P; i.e., $Q = P - ev^T$ where v is an arbitrary vector such that $v^T e = 1$. If P is irreducible and primitive, we may show that Q has spectral radius less than one, moreover its eigenvalues concide with the eigenvalues of P, except for the eigenvalue 1 which is shifted to 0. We show some applications of the shift technique in the numerical solution of structured Markov chains.

A first application arises in the analysis of $M/G/1$-type Markov chains. Here a fundamental problem is the computation of a stochastic matrix G, which solves a suitable nonlinear matrix equation. The shift technique is applied to G, and a nonlinear matrix equation is solved for a matrix $H = G - ev^T$ having spectral radius less than 1.

A second application is the solution of a nonsymmetric algebraic Riccati equation arising in fluid queues. The coefficients of the Riccati equation form a singular M-matrix M. The shift techique is applied to move one zero eigenvalue of M to a suitable nonzero real number.

In both applications, the convergence of existing algorithms is accelerated when the algorithms are applied to the shifted problems.

Assessing transient performance measures of infinite structured Markov chains using steady state techniques. **Benny Van Houdt** (Universiteit Antwerp, Belgium) IC/MT2183/010

This talk features a recent methodology to derive transient performance measures for a broad class infinite structured Markov chains. The main concept of this methodology exists in extending the Markov chain with a mechanism that marks some time epochs according to a set of Markovian rules.

Our interest lies in characterizing the system state at the n-th marked time epoch as well as the mean time at which this n-th marking occurs. The methodology transforms this transient problem into a stationary one by applying a (discrete) Erlangization and constructing a reset Markov chain.

In a second step, we specifically focus on the following classes of discrete and continuous time bivariate Markov chains (MC): Quasi-Birth-and-Death (QBD) MCs, M/G/1- and GI/M/1-type MCs, as well as MCs with a tree-structured state space, being tree-like processes. For each of these classes, a fast algorithm, with limited memory usage, that exploits the block structure of the reset Markov chain to a high degree is developed and is based, among others, on Sylvester matrix equations and fast Fourier transforms.

Attention is also paid to the computational effort required when studying the impact of several possible initial configurations. It is demonstrated that most of the computational work needed for one specific initial system state, can be reused during the computation for subsequent initial states.

Some numerical examples in the area of telecommunication systems are also provided.

Explicit solutions for a general class of Markov processes. **Mark Squillante** (IBM T.J. Watson Research Center, USA), Johan Leeuwaarden (EURANDOM, The Netherlands), Erik Winands (Technische Universiteit Eindhoven, The Netherlands) IC/MT3788/010

We consider a general class of infinite multidimensional Markov processes and derive explicit solutions for their stationary distribution and tail asymptotics. More specifically, we present an exact matrix-geometric solution for the stationary probability vector. We reformulate the probabilistic interpretations of the fundamental solution matrices in terms of Bernoulli excursions, leading to explicit expressions for these matrix elements in terms of hypergeometric functions. We establish asymptotic results on the powers of one of the fundamental solution matrices, which are used together with the corresponding matrix element expressions to obtain explicit large-deviation decay rates.

Bridging ETAQA and Ramaswami's formula for the solution of $M/G/1$-type processes. **Evgenia Smirni** (College of William and Mary, USA), Andreas Stathopoulos (College of William and Mary, USA) IC/MT3780/010

For some time, the method of Ramaswami has been the established way to analyze $M/G/1$-type processes. The ETAQA method, proposed previously, has offered a more efficient alternative for the exact computation of a general class of metrics for $M/G/1$-type processes. However, the stability of ETAQA and its relation to Ramaswami's method were not well understood.

Here, we derive a new formulation that improves the numerical stability and computational performance of ETAQA. As with ETAQA, the resulting methodology which we call newETAQA, solves a homogeneous system of equations to obtain the aggregate probability of a finite set of classes of states from the state space. In contrast to ETAQA, newETAQA constructs its matrix X in a way similar to the method of Ramaswami, decoupling the computation of the probabilities of the first two initial classes of states from the computation of the aggregate probability. Because direct methods are used to solve this system, the decoupling implies an often significant speedup over ETAQA. In addition, we show that the matrix X is an M-matrix, and under certain conditions, X is also diagonally dominant and thus can be factored stably. More importantly, we show that the newETAQA method is just an efficient way to implement Ramaswami's method. We also discuss alternative normalization conditions for Ramaswami's method.

Our numerical experiments demonstrate the stability of our method for both stiff and well behaved processes, and for both low and high system utilizations.

IC/MP444/010: Numerical solutions of Markov chains: techniques and applications. #2

Decision diagrams for the exact solution of Markov models. **Andrew Miner** (Iowa State University, USA) IC/MT3412/010

High-level models of asynchronous systems can easily produce large Markov chains, whose solution is desired to determine performance measures about the system. Although these Markov chains are typically quite sparse, they can still require an excessive amount of storage space if a traditional, sparse matrix representation is used. This talk surveys compact data structures — namely decision diagrams, matrix diagrams, and Kronecker algebra — that can be used to generate and store extremely large Markov chains corresponding to a high-level description. Algorithms are presented for both generation and exact numerical analysis of a Markov chain, using these compact representations.

Decision diagrams for the approximate performance analysis of Markov models of distributed software. **Gianfranco Ciardo** (UC Riverside, USA) IC/MT3413/010

Decision diagrams of various types can be used to encode the exact state space and transition rate matrix of enormous Markov models. However, the exact solution of such models still requires to store at least one real vector with one entry per reachable state, a formidable limitation to the practical use of these encodings. Thus, we discuss automatic techniques for the approximate computation of performance measures when the Markov model can be compactly encoded but not exactly solved. We illustrate the proposed approximation techniques on an ideal target application, the computation of performance measures for a distributed software tasking system.

Markov fluid queue with application to the token bucket analysis. **Marie-Ange Remiche** (Université Libre de Bruxelles, Belgium) IC/MT2850/010

This talk outlines the recent advances for the analysis of the token bucket model for Markovian type traffic pattern. Our analysis makes extensively use of recent results about Markov driven fluid queue. Indeed, it has been shown these last years, that matrix-analytic methods were appropriate tools for the analysis of such a queue. Several efficient algorithms can actually be adapted for measuring the performance of such system.

We first define our token bucket model that is a Markov fluid queue with finite buffer and downwards jumps. Secondly, we clearly identify methods for its analysis and give some numerical results too.

Constructing compact Markov processes for correlated workload modeling. **Armin Heindl** (Universität Erlangen–Nürnberg, Germany) IC/MT2259/010

Unnecessarily large submodels aggravate the state-space explosion problem for Markov models. For example, large models often require various submodels for arrival and service processes, which, moreover, may exhibit correlations. Especially for computer and communication systems modeling, this is the case. The orders of these submodels may multiplicatively flow into the size of the overall model quickly leading to intractable state spaces. To mitigate this effect, compact and correlated Markov processes, in particular Markovian arrival processes (MAPs) of low order, have been developed, which can be used for workload modeling.

This talk discusses different ways how to construct MAPs from information on marginal moments and the autocorrelation function. A canonical form for MAPs of second-order is presented, by means of which we illustrate the flexibility of second-order matrix representations to capture correlation. Such canonical forms do not yet exist for higher dimensions. For this case, we give a brief overview of current approaches to obtain compact MAPs with given properties. Often, an inverse canonical form for matrix-exponential processes, which matches moments and correlation parameters, will play a key role.

IC/MP328/010: Clinical pathodynamics: dynamic modeling of disease in a stochastic system.

Organiser: Donald Trost (Pfizer Global Research and Development, USA)

Tremendous resources are being applied to health care and large amounts of data are collected on individuals undergoing medical observation and treatment. Yet little resource is being applied to the mathematical modeling of the whole human system. Most of clinical science and practice involves the gathering of data and the exercising of clinical judgment in the interpretation and application of these data, but there is little hard science. A more organized, mathematical framework for clinical science is needed.

Systems biology has become a popular topic. However, this is a bottom-up view and will take many years to consolidate into a coherent view of the organism. In the meantime, little progress will be made at the organism level, i.e., in the clinical setting, and medical practice will advance much more slowly than it would with the aid of mathematics.

While we wait for the orderly discovery and construction of the whole organism system, it seems that some significant contributions could be made by attacking the inverse problem, which is how clinical science has developed historically, although without much aid from mathematics. Using an astronomical analogy, clinically we are currently at the stage of Copernicus, Kepler, and Newton.

The primary idea behind pathodynamics is that the organism exists in a state of homeostasis, a dynamic equilibrium, and that dynamic changes from the homeostatic state occur naturally in diseases and artificially during therapeutic interventions or other external influences. One view is that the organism can be treated as a high-dimensional Brownian particle in a universe whose structure is unknown at present, where the dimensions are determined by clinically measurable quantities. Some of the underlying biological mechanisms may be inferred from observing and classifying the patterns of motion of this Brownian particle.

This session is intended to introduce some of these ideas and to stimulate research to advance clinical science.

An introduction to pathodynamics from the view of homeostasis and beyond. **Donald Trost** (Pfizer Global Research and Development, USA) IC/MT2940/010

The human body is a system of discrete and continuous signals. These signals are usually observed and measured by a physician or the physician's assistant or by some form of instrumentation. The diagnoses or clinical judgments are typically derived from changes of state: Change since the last observation, change from a statistical definition of normal, change from an intuitive sense of normal from training and experience, biological asymmetry, change reported by the patient, etc. Medical statisticians quantify these changes using counts, differences, time to an event, and sometimes empirical models relating several variables. These are typically averaged in some way and compared to a probability distribution for decision making. The variability is considered to be noise or a nuisance and is removed. The observed changes and the quantification methods tend to remove much of the biological information found in the variability of the signals. Somehow the dynamics of the system need to be quantified and used as the foundation for medical science.

The concept of Brownian motion was introduced by a biologist almost two centuries ago. Its mathematical foundations were developed by Einstein, Wiener, and others. Although it has been used extensively in statistical physics and mathematical finance, there are relatively few applications in biology and essentially none in clinical medicine. It seems like a natural place to start the study of biological system dynamics.

Homeostasis can be viewed as the state of dynamic equilibrium, while pathology, or more correctly a disease or iatrogenic state, can be viewed as a dynamic disequilibrium or a nonviable static state. This presentation discusses how dynamic models and Brownian motion methods can be applied to the analysis of clinical measurements. This approach has the potential to facilitate the understanding of biological systems on a macroscopic scale, much like thermodynamics did for physical chemistry.

Analysis of longitudinal clinical lab data with latent mixture models. **Jonathan Schildcrout** (Vanderbilt University, USA) IC/MT1474/010

In Phase I, II, and III clinical trials, laboratory data are collected routinely for the purpose of characterizing medication safety. However, for reporting, continuous data are often dichotomized at some threshold value (e.g., 3 times the upper limit of normal), and the longitudinal nature of the data (e.g., repeated measures on individuals) is ignored. Standard pre-marketing pharmaceutical safety analyses often compare the proportions of subjects who cross this threshold value 'at some point in time' during follow-up. Thus, much of the information collected is lost during analyses. Effective characterization of pharmaceutical safety requires analyses that can capture dynamic (and continuous) effects of treatments. By using longitudinal data analysis methods, we may capture mean response differences as functions of time; however in many situations, even those approaches are inadequate. For example, in a number of settings, a large proportion of subjects exhibit no response to treatment and fraction of subjects exhibit substantial responses. Thus, there appears to be some level of responsiveness that varies between subjects, and the information (e.g., genetic) that could explain such differences is unavailable. In such cases, standard longitudinal methods would likely produce a modest treatment effect estimate. In this talk, we will discuss models that posit underlying (latent) responsiveness indicator variables. By approaching analyses in this manner, we are able to address questions that neither the standard analytical methods for pharmaceutical safety nor longitudinal methods can address. Namely, we are able to estimate the probability of being a responder or a non-responder to treatment plus the longitudinal and dynamic treatment effect conditioned on being a responder. Several approaches will be considered, and all discussions will be focused on an analysis regarding the hepatotoxic effect of a single product.

Modeling laboratory measurements from clinical studies. **Gerd Rosenkranz** (Novartis Pharma AG, Switzerland) IC/MT3291/010

The analysis of laboratory measurements and other biomarkers in clinical studies is mainly done by means of data reduction: Often, the worst values from each individual patient are taken into consideration or the incidence of extremely high or low values observed during a trial. Where feasible, graphical representations of the time course of lab measurements are displayed, often for each subject individually. However, only rarely is the attempt made to model the dynamics of the measurements over time.

In this presentation we propose to model the dynamics of lab values by stochastic processes, preferably but not limited to (multivariate) Ornstein-Uhlenbeck processes. This should provide a means to account for potential systematic effects relevant for all or a group of subjects as well as the random variation between subjects. The idea is to estimate parameters of these processes from data in order to characterize a potential effect of drugs or other medical treatments compared to placebo. Results based on simulations and real data will be presented.

Statistical estimation of dynamic parameters in ODE models with applications to HIV and influenza virus infections. **Hulin Wu** (University of Rochester, USA) IC/MT3496/010

I will review the existing statistical methods and present several newly-developed methods for parameter estimation in ODE models based on the data from experiments and clinical studies of HIV and influenza virus. These dynamic parameters may include both constant parameters and time-varying parameters. The proposed estimation methods include the standard nonlinear least-squares method, a Bayesian method and more advanced statistical estimation methods that can avoid numerical evaluations of ODEs. The identifiability problems will be discussed. Real data examples will be presented to illustrate the methodologies and user-friendly software including both ODE simulations and statistical estimation modules will be introduced.

IC/MP3642/081: Advances on computation in financial mathematics.

Organiser: Abdul Khaliq (Middle Tennessee State University, USA)
Co-organiser: Qin Sheng (Baylor University, USA)

The aim of the mini-symposium is to highlight recent advances on computational methods in financial mathematics. Numerical PDE approach is discussed which provids a powerful tools and consistent frameworks for pricing and hedging complex derivatives. The mini-symposium will contain talks presenting new research in topics including, but not limited to, computatinal methods on stochastic volatility models, Jump diffusion models, and exotic options.

Highly-efficient numerical schemes for pricing exotic options. **Abdul Khaliq** (Middle Tennessee State University, USA) IC/MT705/081

Numerical schemes often develop inaccuracies when pricing financial derivatives with non-smooth payoffs, multiple strike prices, and discrete barrier options. Moreover, large errors may occur in estimating the hedging parameters. Averaging the initial data, shifting the grids, projection methods, and smoothing schemes have been tried to deal with the severe discontinuities in the computational domain when pricing and hedging such exotic options. These methods are not typically found sufficient to properly restore the expected behavior of the options. We present a strongly stable (L-stable) and highly accurate method for pricing exotic options. The method is based on Padé schemes and also utilizes partial fraction decomposition to address issues regarding accuracy and computational efficiency. Non-smooth payoffs, which cause discontinuities in the solution, the standard methods are prone to produce large and spurious oscillations in the solution that mislead estimating options accurately. The proposed method does not suffer these drawbacks. The method is seen to be robust and reliable when applied to exotic options such as Complex digital options, Butterfly spread and Barrier options in one and two assets.

Numerical valuation of performance-dependent options. **Thomas Gerstner** (Universität Bonn, Germany) IC/MT374/010

The efficient and accurate valuation of financial derivatives is a central topic in computational finance. Performance-dependent options are an important class of derivatives whose payoff depends on the performance of one asset in comparison to other assets. The fair price of such options can be determined by the martingale approach as a multidimensional integral whose dimension is the number of assets under consideration. Usually, the integrand is discontinuous, though, which makes accurate solutions difficult to achieve by numerical approaches.

For performance-dependent options, we derive a representation of the solution which only involves the evaluation of several multivariate normal distributions. This solution uses novel tools from computational geometry which faciliate the fast enumeration of all cells in a hyperplane arrangement and its orthant decomposition. We show that the arising normal distributions can be efficiently computed using sparse grid quadrature methods. This way, the complexity and the dimensionality of the integration problem can be significantly reduced which allows the efficient pricing of performance-dependent options even for large benchmarks, which is illustrated in several numerical examples.

This research is joint work with Markus Holtz, University of Bonn

Software issues in wavelet analysis of financial data. **Robert Tong** (NAG Ltd, UK) IC/MT1581/081

Wavelet Multiresolution Analysis (WMA) is a tool that is widely applied in many areas of data processing, including financial time series. By revealing the structure of the data at multiple scales, the results of WMA can be used to challenge or confirm underlying assumptions of market models. In many cases, the software used to compute these analyses will have been provided by a third party. We examine here the requirements this imposes on the design and implementation of such software, together with possible limitations which should be taken into account by the user. An important aspect is the desirability of consistent output between different implementations in order to enable valid comparisons to be made. Further, the needs of users to choose an appropriate wavelet basis and produce results relevant to their application must be translated into efficient software in terms of scalability and the pre- and post-processing of data sets. These issues are illustrated with reference to applications such as Foreign Exchange rates.

A semi-smooth Newton method for an inverse problem in option pricing. **Bertram Düring** (TU Wien, Austria), Stefan Volkwein (Universität Graz, Austria), Jüngel Ansgar (TU Wien, Austria) IC/MT1287/081

We present an optimal control approach using a Lagrangian framework to identify local volatility functions from given option prices. We employ a globalized sequential quadratic programming algorithm and implement a line search strategy. The linear-quadratic optimal control problems in each iteration are solved by a primal-dual active set strategy which leads to a semi-smooth Newton method. We present first- and second-order analysis as well as numerical results.

IC/MP3642/081: Advances on computation in financial mathematics. #2

Organiser: Abdul Khaliq (Middle Tennessee State University, USA)
Co-organiser: Qin Sheng (Baylor University, USA)

(For abstract, see session #1 above.)

A direct method for pricing American-style derivatives. **Sebastian Quecke** (Universität zu Köln, Germany) IC/MT977/081

We propose a direct approach for pricing options with early exercise features under fairly general models of the underlying (including Lévy processes). The model of the underlying is described by the conditional probability densities of returns. Risk neutral valuation leads to a nested integral representation of the option price. Using radial basis functions we can compute this price efficiently. The method can also be applied to higher dimensional pricing problems. We present several numerical examples to illustrate the range of applications.

Computation of risk contribution in the Vasicek portfolio credit loss model. **Xinzheng Huang** (TU Delft, The Netherlands) IC/MT1206/081

A risk contribution in the context of portfolio credit loss modeling measures how much each obligor in a portfolio contributes to the total risk. The determination of risk contribution is of practical importance because it is necessary for loan pricing and it can provide limits on large credit exposures. It may also be useful for profitability assessment, asset allocation and portfolio optimization. Within the framework of the Vasicek portfolio credit loss model, we review several methods for the calculation of the marginal risk contribution, among others are importance sampling and saddlepoint approximations. Comparison of different methods are further illustrated by numerical examples.

This is joint work with Cornelis W. Oosterlee and J.A.M. van der Weide.

On the smoothing of Crank–Nicolson method and higher-order methods for pricing barrier-options. **Muhammad Yousuf** (King Fahd University, Saudi Arabia) IC/MT1507/081

Most option pricing problems have nonsmooth payoffs or discontinuous derivatives at the exercise price. Discrete barrier options have not only nonsmooth payoffs but also time dependent discontinuities. In pricing barrier options, certain aspects such as un wanted oscillations are triggered if the asset price becomes too high or too low. Standard smoothing schemes used to solve problems with nonsmooth payoff do not work well for discrete barrier options because of discontinuities introduced in the time domain when each barrier is applied. Moreover, these unwanted oscillations become worse when estimating the hedging parameters, e.g., Delta and Gamma. We have an improved smoothing strategy for the Crank-Nicolson method which is unique in achieving optimal order convergence for barrier option problems. Numerical experiments are discussed for one asset and two asset problems. Time evolution graphs are obtained for one asset problems to show how option prices change with respect to time. The smoothing strategy is then extended to higher order methods using diagonal (m, m) Padé as main schemes, and under a smoothing strategy of using as damping schemes the (0, 2m-1) subdiagonal Padé schemes.

Multi-asset option pricing using radial basis functions . **Sônia Gomes** (Universidade Estadual de Campinas, Brazil), Ulrika Pettersson (Uppsala University, Sweden), Elisabeth Larsson (Uppsala University, Sweden) IC/MT1190/081

The price for a multi-asset option can be computed through solution of a high-dimensional PDE problem, where the number of dimensions correspond to the number of underlying assets. Radial basis function (RBF) methods are attractive in this context because they are meshfree and because they can be spectrally accurate, thus reducing the number of unknowns needed. However, we have found that the performance of the RBF method for a typical problem, such as a European basket call option, is sensitive with respect to the placement of center and collocation points. Furthermore, an unnecessarily high resolution is needed due to the discontinuous derivative in the contract function. In this talk we show what benefits can be gained from using least squares approximation instead of collocation with RBFs.

IC/MP219/010: Advances on modeling in financial mathematics.

Organiser: Abdul Khaliq (Middle Tennessee State University, USA)
Co-organiser: Qin Sheng (Baylor University, USA)

The aim of the mini-symposium is to highlight recent advances on mathematical modeling in financial mathematics. PDE and Monte Carlo approaches are discussed which provide powerful tools and consistent frameworks for pricing and hedging complex derivatives. The mini-symposium will contain talks presenting new research in topics including, but not limited to, stochastic volatility models, regime switching, credit risks, and multi scale models.

Homogeneous groups and multiscale intensity models for multiname credit derivatives. **Ronnie Sircar** (Princeton University, USA) IC/MT1340/081

The pricing of basket credit derivatives is contingent upon (i) a realistic modeling of the firms' default times and the correlation between them; and (ii) efficient computational methods for computing the portfolio loss distribution from the firms' marginal default time distributions. We revisit intensity-based models, and with the aforementioned issues in mind we propose improvements ii) via incorporating fast mean-reverting stochastic volatility on the default intensity processes; and iiii) by considering a hybrid of a top-down and a bottom-up model with homogeneous groups within the original set of firms. We present a calibration example, and discuss the relative performance of the approach.

This is joint work with Evan Papageorgiou.

Multi-level quasi-Monte-Carlo path calculations for finance. **Michael Giles** (University of Oxford, UK), Ben Waterhouse (University of New South Wales, Australia) IC/MT1134/081

In this talk we will present advances in the multilevel Monte Carlo approach recently introduced for estimating expectations arising from stochastic path simulations. One focus is on improvements in both complexity and actual computational cost using Milstein's method instead of the Euler-Maruyama discretisation. In this context, particular attention is paid to the treatment of lookback, barrier and digital options. The second focus is on the introduction of Quasi-Monte Carlo techniques, in particular lattice rules and Sobol sequences. This leads to further substantial computational savings, yielding a very practical method for a wide range of option pricing applications.

Calibration of forward rate volatility in a Bayesian framework. **Christoph Reisinger** (University of Oxford, UK) IC/MT1141/081

The objective of this talk is the calibration of a time-homogeneous, hump-shaped volatility function to a time series of LIBOR rates. The observed data are used to estimate simultaneously the distribution of forward rates as unobservable driving processes, and the model parameters. Acknowledging the presence of observation noise in a Bayesian setting, we obtain parameter distributions that yield stable and accurate estimates together with measures for their uncertainty. This is joint work with Hugo Para, extending recent work by Bhar, Chiarella, Hung and Runggaldier.

Finite-horizon portfolio selection with transaction costs. **Min Dai** (National University of Singapore) IC/MT511/010

This paper concerns portfolio selection of a CRRA investor who faces proportional transaction costs and finite time horizon. From the angle of stochastic control, it is a singular control problem, whose value function is governed by a time-dependent HJB equation with gradient constraints. We reveal that the problem is equivalent to a parabolic double obstacle problem involving two free boundaries that correspond to the optimal buying and selling policies. This enables us to make use of the well developed theory of obstacle problem to attack the problem. The $C^{2,1}$ regularity of the value function is proven and the optimal investment policies are completely characterized. Relying on the double obstacle problem, we extend the binomial method widely used in option pricing to determine the optimal investment policies. Numerical examples are presented as well.

IC/MP219/010: Advances on modeling in financial mathematics. #2

Co-organiser: Qin Sheng (Baylor University, USA)

(For abstract, see session #1 above.)

Multiname and multiscale default modeling. **Knut Solna** (University of California, Irvine, USA) IC/MT1638/081

We consider multiname default modeling using a reduced-form modeling approach. The model is based on a multiscale model for the hazard rates of the underlying names. Such default modeling is important in the context of pricing for instance Collaterized Debt Obligations (CDOs) and we analyze the impact of volatility time scales on the default distribution and CDO prices.

The Heston stochastic-volatility model: parameter estimation through maximum likelihood and filtering. **Francesco Zirilli** (Università degli Studi di Roma "La Sapienza", Italy) IC/MT956/081

Let us suppose that the dynamics of the stock prices and of their stochastic variance is described by the Heston model, that is by a system of two stochastic differential equations with a suitable initial condition. The aim of this paper is to estimate the parameters of the Heston model and one component of the initial condition, that is the initial stochastic variance, from the knowledge of the stock and option prices observed at discrete times. The option prices considered refer to an European call on the stock whose prices are described by the Heston model. The method proposed to solve this problem is based on a filtering technique to construct a likelihood function and on the maximization of the likelihood function obtained. The estimated parameters and initial value component are characterized as being a maximizer of the likelihood function subject to some constraints.

The solution of the filtering problem, used to construct the likelihood function, is based on an integral representation of the fundamental solution of the Fokker–Planck equation associated to the Heston model, on the use of a wavelet expansion to approximate the integral kernel appearing in the representation formula of the fundamental solution, on a simple truncation procedure to exploit the sparsifying properties of the wavelet expansion and on the use of the Fast Fourier Transform (FFT). The use of these techniques generates a very efficient and fully parallelizable numerical procedure to solve the filtering problem, this last fact makes possible to evaluate very efficiently the likelihood function and its gradient. As a byproduct of the solution of the filtering problem we have developed a stochastic variance tracking technique that gives very good results in numerical experiments.

The maximum likelihood problem used in the estimation procedure is a low dimensional constrained optimization problem, its solution with ad hoc techniques is justified by the computational cost of evaluating the likelihood function and its gradient. We use parallel computing and a variable metric steepest ascent method to solve the maximum likelihood problem. Some numerical examples of the estimation problem using synthetic and real data, that is data relative to an index of the Milano stock exchange (S&PMIB3O), obtained with a parallel implementation of the previous numerical method are presented. Very impressive speed up factors are obtained in the numerical examples using the parallel implementation of the numerical method proposed. The website: http://www.econ.univpm.it/pacelli/mariani/finance/w1 contains animations and some auxiliary material that helps the understanding of this paper and makes available to the interested users the computer programs used to produce the numerical experience presented.

An optimal variance reduction method for density estimation. **Ahmed Kebaier** (Université de Paris–Dauphine, France), Arturo Kohatsu-Higa (, Japan) IC/MT1549/081

This work is in collaboration with Arturo Kohatsu-Higa. We study the problem of density estimation for non-degenerate diffusions using kernel functions. Thanks to Malliavin calculus technics, we obtain an expansion of the discretisation error. Then, we introduce a new control variate method in order to reduce the variance in the density estimation. We prove a stable law convergence theorem of type Jacod Kurtz Protter, for the Malliavin derivative of the error process, which leads us to get a CLT for the new variance reduction algorithm. This CLT gives us a precise description of the optimal parameters of the method. The numerical results confirm the efficiency of the method.

American options in regime switching Levy models. **Sergei Levendorskiĭ** (University of Texas at Austin, USA), Svetlana Boyarchenko (University of Texas at Austin, USA) IC/MT499/010

In the talk, a general framework for pricing of perpetual American and real options in regime-switching Lévy models is presented. In each state of the Markov chain, which determines switches from one Lévy process to another, the payoff stream is a monotone function of the Lévy process labelled by the state. This allows for additional switching within each state of the Markov chain (payoffs can be different in different regions of the real line). The payoffs and riskless rates may depend on a state, which allows for jumps in prices at moment of switching. Special cases are stochastic volatility models and models with stochastic interest rate; both must be modelled as finite-state Markov chains. We construct iteration procedures and prove that iterations converge to the solution of the optimization problem monotonically. The procedures are numerically efficient even if the number of states is large provided the transition rates are not large w.r.t. the riskless rates. As first applications, we solve exit problems for a price-taking firm, and pricing problems for American options with infinite and finite time horizon. In the latter case, we use a modification of Carr's randomization procedure for regime-switching models.

IC/MP1894/081: Financial modeling with jump processes.

Organiser: Christoph Schwab (ETH Zürich, Switzerland)
Co-organiser: Rama Cont (Columbia University, USA)

In the past decade, financial models with jump processes have become widely accepted as generalization of the classical Black–Scholes models.

This minisymposium will review some of the latest developments in this area, in particular:

- multidimensional models with jumps: dependence modeling, Lévy copulas, numerical methods for multidimensional models;
- simulation and estimation: efficient simulation of multivariate models, econometrics of jump processes, realized volatility/bi-power variation;
- partial integro-differential equations (PIDEs) and computational methods;
- interest rate and credit risk models with jumps and their efficient analytical and numerical treatment.

Recovering Levy processes from option prices: stable algorithms for an ill-posed inverse problem. **Rama Cont** (Columbia University, USA) IC/MT2921/081

In the class of exponential Lévy models, where the risk neutral dynamics of an asset price S_t is expressed as $S_t = \exp X_t$ where X_t is a Lévy process determined by its Lévy triplet (b, σ, ν) where $\sigma \geq 0$, ν is a Radon measure on $\mathbb{R} - \{0\}$ with $\int \nu(dx)(1 \wedge x^2) < \infty$. Option prices in this model can be characterized as solutions of partial integro-differential equations (PIDEs). A preliminary step in using the model is to solve the following *inverse problem*:

Given a set of prices of call options $C(t, S, T_i, K_i), i \in I$, find $\sigma \geq 0$ and a Lévy measure ν such that

$$\forall i \in I, C(t, S, T_i, K_i) = e^{-r(T-t)} E^{(\sigma,\nu)}[(S(T_i) - K_i)^+ | S_t = S].$$

This is equivalent to an inverse problem for the corresponding partial integro-differential equation (PIDE). The issue is to find stable algorithms for solving this ill-posed inverse problem in the realistic case where the number of observations is finite.

After pointing out the drawbacks of standard parametric output least squares methods, we present various *nonparametric* approaches to this problem. The first, jointly developed with P. Tankov, is a regularization method based on relative entropy. The second, jointly developed with M. Rouis, uses Tikhonov regularization and computation of the solution by solving an adjoint PIDE. In each case we provide a theoretical analysis of the calibration algorithm, discuss numerical implementation issues and assess their empirical performance using market data.

Finally, we discuss issues related to calibration of American options, which lead to inverse problems for free-boundary PIDEs.

Time-changed intensity models for portfolio credit risk. **Philipp Schönbucher** (ETH Zürich, Switzerland) IC/MT2022/081

In this paper, we present a general methodology to introduce dependence in multivariate intensity-based credit risk models using stochastic time changes of the underlying processes. We analyze the properties of the resulting models, compare them to existing multivariate intensity-based credit risk models and present an efficient methodology for the numerical implementation and calibration of such models.

Hedging options in presence of jumps. **Peter Tankov** (Université Paris VII, France), Rama Cont (Columbia University, USA), Ekaterina Voltchkova (Université Toulouse I, France) IC/MT2207/081

We study the problem of hedging options when the underlying asset is described by a process with jumps. We compare various hedging strategies using the underlying asset and a set of liquid options and examine the properties of the hedging error, both theoretically and through numerical experiments. We illustrate in particular that using *sensitivities* to compute Δ-neutral and Γ-neutral hedge ratios can lead to a large hedging error, and illustrate how such strategies can be improved by using a risk-minimizing approach to hedging and by taking positions in options.

Keywords: option pricing, hedging, integro-differential equations, finite difference methods, Lévy process, jump-diffusion models.

Pricing of financial derivatives using multivariate jump processes. **Christoph Winter** (ETH Zürich, Switzerland) IC/MT4579/081

For one-dimensional Lévy processes option pricing by solving the corresponding partial integro-differential equations has been studied by several authors. We extend the results to multivariate jump processes using Lévy copulas. The partial integrodifferential equations are discretized by sparse tensor product Finite Element spaces. Since the multi-dimensional tail integrals have singularities at the origin and on the axes, variable order composite quadrature formulas are employed for the computation of the integral part. Numerical examples are given.

This is joint work with N. Reich.

IC/MP306/013: Recent developments in the stochastic exit problem.

Organiser: Samuel Herrmann (École des Mines Nancy, France)
Co-organiser: Nils Berglund (Centre de Physique Théorique - CNRS, France)

The escape of a Brownian particle from a potential well, under the influence of external noise, was studied by Eyring and Kramers in the 1930s. The mathematical formulation of the phenomenon leads to the so-called stochastic exit problem. Consider a diffusion process, described by the Itô stochastic differential equation

$$\mathrm{d}X_t^\epsilon = b(X_t^\epsilon)\mathrm{d}t + \sqrt{\epsilon}\sigma(X_t^\epsilon)\mathrm{d}W_t\,,$$

where the noise intensity ϵ is a small parameter, and W_t is a Brownian motion in $\mathbb{R}^d$. Given a bounded domain $D \subset \mathbb{R}^d$, the exit problem consists in determining the small-ϵ asymptotics of the distribution of the first-exit time

$$\tau^\epsilon = \inf\{t > 0 :\ X_t^\epsilon \notin D\},$$

and of the exit location X_{τ^ϵ}.

Since the first rigorous results were obtained by Freidlin and Wentzell in the late 1960s, using techniques from the theory of large deviations, the problem has been addressed by a variety of rigorous approaches, including formal and systematic asymptotic expansions and potential theory, as well as by various numerical techniques.

The results are relevant for many applications: modern communication systems, stochastic stability of structures, modern theory of finance, climate models, the dynamics of macromolecules, metastability, stochastic resonance, etc.

The aim of this minisymposium is to present recent developments in the classical exit problem, including precise subexponential asymptotics for gradient systems, cycling and skewing phenomena for nongradient systems, and their applications, but also recent results for more general types of noise.

Small eigenvalues of reversible diffusions in the metastable regime. **Michael Eckhoff** (Universität Erlangen–Nürnberg, Germany) IC/MT3995/0

For generic $F : \mathbb{R}^d \to \mathbb{R}$ with finitely-many local minima and Brownian motion $(W_t, t \geq 0)$ the randomly perturbed dynamical system

$$dX_t = -\nabla F(X_t)dt + (2\varepsilon)^{1/2}dW_t, \quad \varepsilon > 0,$$

exhibits several quasi-invariant states corresponding to the local minima on the long term run as ε becomes small. They determine the in $1/\varepsilon$ exponentially small eigenvalues of the generator and are given in a precise way as the inverse of expected relaxation times of the corresponding quasi-invariant states. Their rescaled distribution functions converge uniformly to that of an exponential random variable.

Large fluctuations, classical activation, quantum tunneling, and phase transitions. **Daniel Stein** (New York University, USA) IC/MT3677/0

I will discuss two broad classes of physically dissimilar problems, each corresponding to stochastically driven escape from a potential well. The first class, often used to model noise-induced order parameter reversal, comprises Ginzburg-Landau-type field theories defined on finite intervals, perturbed by thermal or other classical spatiotemporal noise. I will present recent results from collaborative efforts applying our theory of escape in these types of systems to two different problems: the thermally induced breakup of monovalent metallic nanowires, and stochastic reversal of magnetization in thin ferromagnetic annuli.

The second class comprises systems in which a single degree of freedom is perturbed by both thermal and quantum noise. Each of the two above classes of problem possesses a transition in its escape behavior, at a critical value of interval length and temperature, respectively. It is shown that there exists a mapping from one class of problems to the other, and that their respective transitions can be understood within a unified theoretical context. Finally, I will explore the depth of the analogy between the two classes of problems, and discuss to what extent each case exhibits the characteristic signs of critical behavior at a sharp second-order phase transition.

Dynamical systems with heavy-tail Levy noise. **Ilya Pavlyukevich** (Humboldt University Berlin, Germany) IC/MT3679/0

We consider a dynamical system in $\mathbb{R}$ driven by a vector field $-U'$, where U is a multi-well potential satisfying some regularity conditions. This dynamical system is perturbed by a heavy-tail Lévy noise of small intensity. For the perturbed system, we determine the law and mean value of the transition times between potential wells and formulate results on metastablity. We also discuss how global optimisation problems can be solved with help of simulated annealing with big jumps.

Simulation of exit times and positions for the Brownian motion and diffusions. **Madalina Deaconu** (INRIA Lorraine, France), Antoine Lejay (INRIA Lorraine, France) IC/MT3670/0

Monte Carlo methods are sometimes the only way to deal with some deterministic problems (solving some PDE, computing some effective coefficients). We present here some recent developement in the simulation of the Brownian motion and SDEs, that can be useful when one needs some precise estimation of the first exit times and positions from some domain, or when one whishes to estimates an exit probability which is small or the tail of the distribution function of the exit time. Applications will also be presented.

From joint works with Antoine Lejay (Projet OMEGA, Institut Elie Cartan, Nancy, France)

IC/MP299/010: Shape and size in medicine, biotechnology and material Science.

Organiser: Vincenzo Capasso (Università degli Studi di Milano, Italy)
Co-organiser: Alessandra Micheletti (Università degli Studi di Milano, Italy)

Shape analysis deals with the geometrical information on objects that is left after location, scale and rotation effects are removed. If scale effects are not removed, then we are led to form (size and shape). In applications, bodies rarely have exactly the same shape within measurement error; hence randomness of shapes need to be taken into account. Thanks to the development of information technologies, the last decade has seen a considerable growth of interest in the statistical theory of shape and its application to many and diverse scientific areas.

Often the diagnosis of a pathology, or the description of a biological process mainly depend on the shapes present in images of cells, organs, biological systems, etc., and mathematical models which relate the main features of these shapes with the correct outcome of the diagnosis, or with the main kinetic parameters of a biological systems are still not present. In material sciences optimisation for quality control require methods of statistical shape analysis.

From the mathematical point of view, shape analysis uses a variety of mathematical tools from differential geometry, geometric measure theory, stochastic geometry, etc. As far as applications are concerned, we emphasize here topics which are relevant in medicine, biotechnology and material sciences. We deal with direct and inverse problems. Among direct problems, spatio-temporal pattern formation deals with the analysis of how patterns are created and developed in biology. Among

inverse problems, various statistical techniques of shape analysis will be proposed to measure in a quantitative way the random variability of objects.

Variational surface matching and applications in medicine. **Hans Lamecker** (Zuse-Institut Berlin, Germany), Hans-Christian Hege (Zuse-Institut Berlin, Germany), Peter Deuflhard (Zuse-Institut Berlin, Germany) IC/MT1937/083

Shape matching or registration is a prerequisite for quantitative shape analysis. It is a fundamental ingredient for reconstruction, recovery, tracking, detection and transformation of shapes. These techniques are applied in fields such as computer graphics, computer vision, pattern recognition, robotics, image processing and many more, of which it is almost impossible to give full account.

In this talk, shape will be understood as geometric information of a three-dimensional object, i.e. we are only interested in the boundary representation of a given object, thereby neglecting its inner structure. The talk will focus on the task of comparing shapes. This task relies on the ability of identifying corresponding points on different shapes, which is often referred to as the *correspondence problem*. We will consider only inter-object registration. For this case, the usual elastic deformation approach based on "material properties" is not well-suited.

Two main challenges in establishing this correspondence between 3D shapes have to be faced: (1) to define a distance measure for characterization of the similarity of two surfaces and (2) to formulate, discretize and solve the correspondence problem directly.

(1) As for the distance measure, we will propose a functional for establishing correspondence between 3D shapes. It has been derived by invariance considerations and a purely differential-geometric characterization of shape, reflecting the fundamental theorem of surface theory.

(2) As for solving the correspondence problem, we show first steps toward an adaptive multilevel FE method associated with minimizing the proposed distance functional.

Among the large variety of potential applications of shape matching the talk will restrict its attention to statistical shape modeling. There, the idea is to capture the *essential degrees of freedom* of variations within a well-defined training database. Correct correspondence between shapes is essential in order to capture the true variability. Two important applications of statistical shape modeling in medicine will be presented:

(A) Atlas-based segmentation of 3D image data for oncological liver surgery. The segmentation of the liver tissue is an important prerequisite for liver surgery planning. In clinical routine, manual segmentation of the liver parenchyma is too time consuming (about one hour per data set). The segmentation time will be even longer with increasing number of slices from improved CT scanners. Therefore methods have to be devised that require little interaction time. We have developed a statistical 3D shape model of the liver tissue for the automatic segmentation of contrast enhanced CT data. The algorithm has been validated on more than 30 patient data sets acquired from different scanners, yielding an accuracy of about 2 mm average surface distance.

(B) Reconstruction of malformed shapes in cranial neurosurgery. Skull deformities can lead to increased intra-cranial pressure, vision, hearing, and breathing problems. Research on the correction of underlying disorders on the cellular level is still being carried out. Thus, patients with craniosynostosis currently depend on surgical intervention for preventing or reducing functional impairment and improving their appearance. A definition of the correct target shape after surgery is missing. The most important and in many cases only indication of the best possible approximation of the skull shape to the unknown healthy shape is left to the subjective aesthetic assessment of the surgeon. This prevents impartial control of therapeutic success and aggravates guidance and instruction of the remodeling process for inexperienced surgeons. A statistical shape model of the cranium was created from 21 MRI data sets. In a first clinical application, the statistical model was pre-operatively matched to a patient and taken to the operating room to assist the reshaping process.

New level-set techniques for the crack-detection problem. **Diego Álvarez** (Universidad Carlos III de Madrid, Spain), Oliver Dorn (Universidad Carlos III de Madrid, Spain), Miguel Moscoso (Universidad Carlos III de Madrid, Spain) IC/MT4114/083

In this talk we address the problem of detecting thin cracks from boundary data. The cracks are modeled as thin shapes of fixed thickness which need to be reconstructed from boundary electrical measurements. We introduce an extension of the level set technique for modelling these thin shapes. Two level set functions are employed for modelling these crack-type structures. The first one models the location and form of the crack, and the second one models its length and connectivity. A gradient based method is derived in order to define iterative updates for both level set functions with the goal to reduce and eventually minimize a given least squares data misfit functional. These successive corrections of the two level set functions correspond to an evolution of the thin shape or crack during the reconstruction. We present numerical experiments which demonstrate that our technique is able to recover disconnected thin shapes or cracks from noisy simulated boundary data.

The stochastic geometry of kinetic-driven crystallization processes: modelling, simulation and statistical analysis. **Stefano Patti** (Università degli Studi di Milano, Italy), Alessandra Micheletti (Università degli Studi di Milano, Italy), Vincenzo Capasso (Università degli Studi di Milano, Italy), Martin Burger (Universität Münster, Germany), Marco Rubbo (Dip.Scienze Mineralogiche e Petrologiche. Torino, Italy), Dino Aquilano (Università degli Studi di Torino, Italy) IC/MT4144/083

Crystal growth is a topic that has been widely studied by mathematicians and physicists. We propose a new model by taking account of kinetic contributions only; this model is coherent with the classical Stefan Problem proposed in the literature. In particular we solve numerically the case of multiple growth, by considering a stochastic contribution due to the random nucleations in time and in space; therefore a birth-and-growth process arises. The coupling of the growth dynamics with the evolution of the underlying field of the concentration of matter causes the stochastic geometry of the crystals, which present a strong spatial non homogeneity. Then we perform on the numerical simulations some measurements on the evolving geometry of the process, e.g. the size of the crystals, the volume fraction of the crystal phases, etc. Since some of these random quantities may be represented by random functions, we apply some functional data analysis techniques to solve the related statistical problems. In particular we perform a functional regression of the expected size of the crystals with respect to the kinetic parameters of growth.

Configurations of steps during growth limited by surface processes. **Marco Rubbo** (Dip.Scienze Mineralogiche e Petrologiche. Torino, Italy) IC/MT4171/083

The talk deals with the configuration of growth steps originated at the outcrop of a screw dislocation on a crystal face. These steps wind around the dislocation lines forming growth hillocks on a crystal face.To describe a growth hillock let's consider its intersection with a plane perpendicular to the crystal face: such intersection is a line consisting, in the crystal growth jargon, of terraces and rises (the steps). When seen on an orthogonal projection over the crystal face, the steps form a peculiar pattern, the so called growth spiral; the spiral arms are the steps projection and the distance between consecutive arms gives the width of the terraces. The profile of a hillock is defined by the set of terraces lengths and steps heights. The smallest height of a step is a property typical of each crystal face. From a physical point of view, the distance between steps depends on: -the kinetics of exchange of matter between the crystal and the mother phase, -the frequency of production of steps at the dislocation, -the kinetic interaction among growth hillocks; -other causes which are not affecting the main features of the model we are going to present. By kinetic interaction among growth hillocks we mean the overlap of the concentration fields of growth units around contiguous hillocks. That interaction determines the rate of the outer steps of the hillocks and this fact constrains the outer steps distance. When the distance between two consecutive steps becomes nil they coalesce in one step of multiple height. In order to model the transient configuration of the steps and to look for the existence of a steady state, we formulate a system of reaction-diffusion equations solved by a numerical method. We will present an up to date review of the different configurations of steps obtained, depending on the initial and boundary conditions chosen; moreover we will discuss their long term behaviour.

IC/MP299/010: Shape and size in medicine, biotechnology and material Science. #2

Organiser: Vincenzo Capasso (Università degli Studi di Milano, Italy)
Co-organiser: Alessandra Micheletti (Università degli Studi di Milano, Italy)

(For abstract, see session #1 above.)

The theory of size functions applied to problems of statistical shape analysis in bio-medicine. **Alessandra Micheletti** (Università degli Studi di Milano, Italy) IC/MT980/083

The solution to the problem of describing a *shape* via functions taking values in a finite-dimensional space, without loosing relevant information, is needed for the mathematical and statistical analysis of random objects. Recently new geometrical descriptors of shapes, the size functions, have been proposed. These functions are able to capture *globally* the geometric characteristics of an object, differently from landmarks (which usually are specific geometric descriptors, chosen by an expert), which are widely used in literature, but whose results in the statistical analysis are strongly dependent on their choice, leading to a sort of subjective quantitative analysis. Size functions depend on the choice of a measuring function, and usually only a small number of choices lead to different statistical results. The theory of size functions has been developed mainly in a deterministic framework. A first attempt of joining this theory with randomness and to develop the related statistical analysis is here presented. The approximation of size functions with their discrete counterpart leads to the formulation of suitable algorithms which may compute a graphical representation of the size function associated with a shape. The main features of the shape are thus described by a finite number of points and lines on a plane. The descriptor is robust, since small variations in the shape produce small variations in the location of such points and lines. Then confidence regions for different families of shapes, and thus solutions to classification problems can be provided via these tools. Applications to problems arising in biomedicine, in particular to the automatic classification of different types of tumor cells from their shape, will be presented.

Patterns and waves in some models of population dynamics with non-local consumption of resources. **Vitaly Volpert** (Université Claude Bernard Lyon I, France) IC/MT1791/083

We consider nonlinear integro-differential equations and systems of equations describing some problems in population dynamics with nonlocal consumption of resources. Their solutions show complex nonlinear dynamics with various patterns and waves. We study them in 1D and 2D cases. In the context of population dynamics the mechanism of pattern formation discussed in the present work can be related to intra-specific competition. The model provides a possible explanation of the emergence and of the evolution of biological species.

A brief overview of stereology: the art of geometric sampling. **Luis Cruz-Orive** (Universidad de Cantabria, Spain) IC/MT5007/083

Stereology is a interdisciplinary science which dictates rules of geometric sampling to estimate quantities defined on spatial objects (e.g. biological, or mineral structures) such as volume, number of cells, voids or inclusions, surface area, length of curvilinear structures, etc. The relevant information is the intersection between the object and a test probe of points, curves, planes, or full dimensional subsets with known geometric properties. The discipline providing the necessary link is integral geometry. The methodology borrows heavily from sampling theory, as opposed to reconstruction, and it applies to objects with no, or rather weak, assumptions about shape. Image analysis may play a role in data acquisition, but not in the sampling design. In design based stereology the object of interest is assumed to be non random, and unbiased estimation is warranted by a proper random mechanism for the probe hitting the object. This is the stereology applied to bounded objects, specially in biosciences. When probe replication is easily available unbiasedness is more important than precision, because the latter can be increased at will by increasing the sampling intensity. On the other hand, in model based stereology the object is regarded as a realization of a random closed set, usually stationary; in this case, the location of the probe may be arbitrary. Point process theory is a subsidiary discipline here. In all cases, the prediction of the variance due to sampling with systematic geometric probes, is usually a nontrivial, challenging problem. In the lecture an informal excursion is made to various aspects of stereology, with real examples.

Texture classification by statistical learning from morphological image processing. **Dominique Jeulin** (Ecole des Mines de Paris, France) IC/MT2387/083

The automatic extraction of objects in images is usually made by means of shape descriptors based on combinations of geometrical measurements (area, perimeter, size, orientation...) on already extracted objects. The optimal choice of parameters for shape classification can be obtained by multivariate statistical analysis of data obtained on populations of objects.

Complex images can contain various textures and defects, which cannot be easily extracted by a standard segmentation process, involving to develop very tedious algorithms valid for a single case of application.

In the present study, we propose a generic approach for the classification of textures, based on the use of morphological descriptors at the level of pixels. The mains steps of the approach are as follows.

- Each pixel of an image is described by a vector accounting for information in its neighborhood at different scales. Two families of descriptors are used at this level: the curvelets[2] and morphological sizings by opening and closing transformations [1]. Typically, the curvelets are obtained by a linear filtering of each 100×100 neighborhood of every pixel by 26 wavelets with different orientations and ranges. The morphological operators are non linear filters. The opening, obtained by an erosion followed by a dilation by a given structuring element, keeps bright parts of the image which can contain the structuring element, while the closing operation (dilation followed by an erosion) removed dark zones in an image. Increasing sizes of structuring elements are used, to cover the range $[2, 4, 8, 16, 32] \times 2 + 1$ in the present case. For a given type of structuring element (square, horizontal or vertical segment), we keep the difference between the open images at steps n and $n+1$, as well as between the closed images at steps $n+1$ and n. Therefore each pixel is described by a vector with 30 morphological components (5 sizes for 3 structuring elements and 2 operations), generating a file of 30 images.
- In a second step, every pixel is considered as an observation in a multidimensional space. Various techniques of multivariate statistical data analysis are used to generate a classification of pixels according to their environment: the PCA (principal components analysis), and the Kmeans algorithm (with a prior given number of classes)[3]. To avoid an over representation of pixels corresponding to dominant classes, a sampling of the pixels is generated for the multivariate analysis, and a classification of the pixels is performed according to their distance to the centers of the classes.
- In some cases, isolated pixels in the image can be affected to separate textures, generating noise in the segmentation. This is corrected by morphological filtering of the resulting image.

The approach is illustrated for two examples of applications in two different areas: the automatic extraction of textures and of defects on steel surfaces, and the texture based classification of biological cells.

IC/MP77/008: Cointegrating, Kalman-filtering of economic time-series, alpha-stable distributions.

Organiser: Jean-Francois Emmenegger (Université de Fribourg, Switzerland)
Co-organiser: Elena Pervukhina (Sevastopol National Technical University, Ukraine)
Co-organiser: Tamara Bardadym (V.M.Glushkov Institute of Cybernetics, Ukraine)

The subject is situated in the domain of applied econometrics and economic time series analysis. Starting from actual economic questions arising in different countries the appropriate data and tools are set up. Thus, the proposed treated questions are as follows.

1) What quantity of given basic foods can a representative household or individual purchase with the earning power of its labour, represented by the mean monthly total wages, at any cross-sectional time point within a given period?
2) Is the consumer price index in equilibrium with mean total wages or with newly proposed price indices within a given period?
3) How to smooth and to forecast the prices of basic food in a given period with as less as possible a priori available information containing observational errors?
4) How do behave the returns of Eastern European Financial Markets since 1991?

The tools to analyse the questions are as follows.

1), 2) Cointegration analysis of economic time series, initiated by Engle and Granger (Nobel Prize in 2003), is the method to discover long-run equilibrium relationships between two or more analysed economic variables. Such analyses are of overall importance to verify equilibrium conjectures of economic theories.
3) An extension of the Kalman filter techniques used in state space time series filtering leading to adaptive filters, based on the minimisation of the Kullback–Leibler divergence criterion are proposed. Algorithms working under conditions of deficient information concerning the knowledge of the distribution of the error terms of the system are discussed.
4) The overall importance of α-stable distributions in opposition to the normal distribution to describe the returns' distributions is worked out. The Rachev-ratio and the STARR ratio as alternative to the Sharpe ratio are presented.

Parts of these subjects have been published in several papers like the International Journal of Applied Mathematics and in the WSEAS Transactions on Mathematics.

ARIMA, cointegration, Kalman-filter, alpha-stable distributions. **Jean-Francois Emmenegger** (Université de Fribourg, Switzerland) IC/MT683/008

Time-series econometrics has rapidly evolved in the last decades. Its progress is explained by its successful applications in macro- and micro-econometrics and especially by its rapid evolution in mathematical finance. The cointegration revolution has given great importance to this field, because linear cointegrating relations have economically interpretable coefficients, if they are related to questions of economics. Structural breaks have also got its methodology with Kalman filter applications as well as specific break detection algorithms. As economic theories also present time dependent dynamic problems, like the formation of capital intensity through the Solow equation, the mathematics of impulsive-difference equations has also been used to develop new solutions to these questions, cumulating to the impulsive Solow equation. The present international group around the project 'Analysis of Economic and Environmental Time Series', initiated since the 3rd ICIAM'95 in Hamburg, has worked in this field for more than 10 years and presents its theoretical results in terms of four fields of knowledge, probability, estimation, modelling and forecasting. But it has to be especially emphasised that this group has worked in this field with the aim to apply and combine the different mentioned modern methods of time series econometrics to practical subjects of real economy. Applications exist in the field of electricity consumption, purchasing power and consumer price index analyses, as well as dynamic modelling of capital intensity, Kalman filtering of price and ecological time series, but also the practical determination of alpha-stable distributions of index returns with the Fast

Fourier Transform Algorithm in empirical finance. These results are presented at this Minisymposium of the 6th ICIAM'07 in Zurich.

Cointegration applied to purchasing-power analysis of mean Ukrainian total wages. **Tamara Bardadym** (V.M.Glushkov Institute of Cybernetics, Ukraine), Jean-Francois Emmenegger (Université de Fribourg, Switzerland) IC/MT681/008

The main purpose of this paper is to propose a method of measurement of the purchasing power in Ukraine in approximately the last decade and to determine its evolution. Nineteen monthly price time series of basic food, the time series of the Consumer Price Index (CPI) and the Mean total Wages (MTW), published by the State Committee of Statistics of Ukraine (Derzhkomstat) have been selected within the period of November 1991 to December 2004. Preliminary studies of stationarity are undertaken to establish their degree of integratedness with a battery of adequate unit root tests. A cointegration analysis of couples of one of these price time series, respectively the CPI, and the MTW time series are undertaken within sub-periods of the interval 1991 to 2004, yielding linear functions between both selected time series, in order to establish tentative long-run equilibrium relations which are economically interpretable in terms of purchasing power analysis.

Adaptive time-series filters to smooth and forecast economic variables. **Elena Pervukhina** (Sevastopol National Technical University, Ukraine) IC/MT602/008

Classic filtering and prediction problems are solved on the basis of a differentiable matrix functional, defined on the coefficient matrix of the filter. The functional presents an information measure between the distribution parameters of the state vector and its tentative estimation and is well known as Kullback information divergence. The coefficient matrix provides the minimum of the functional and leads to a distribution for which the parameters are closest with respect to the distribution parameters of the real state vector of the system. Moreover, it needs only current observations of the system. The correspondent algorithm allows estimating the system state without a priori information on it and on the noise covariance, based on the observations. After data accumulation the filter acquires features closed to optimal filter characteristics. In particular, the norm of the covariance matrix of the estimation errors converges to the covariance matrix of errors after estimation of the optimal filter, using all the available a priori information. The numerical examples are connected with applied problems of smoothing and forecasting some ecological data from Crimea and some economic data from Ukraine with as less as possible available information on the noise of the system.

The stable Paretian hypothesis of Mandelbrot and the Gaussian hypothesis of Bachelier, ARMA and GARCH modelling for emerging Eastern European financial markets. **Anna Serbinenko** (Universität Karlsruhe, Germany) IC/MT4530/085

Bachelier (1900) had the path-breaking idea to model the returns of security and commodity markets as a random walk, meaning that successive differences of returns are Gaussian distributed. Despite of this fundamental idea, named the Gaussian hypothesis, Mandelbrot (1963) and Fama (1965) postulated that the distributions of the returns do not behave like this, but behave like the more general stable distributions, containing skewness and kurtosis. Mandelbrot called his concept the stable Paretian hypothesis. Rachev (2000) and other authors confirmed in their research work Mandelbrot's theses. Since then, a controversy between these both distributional hypotheses continue to exist in mathematical finance. Serbinenko and Emmenegger (2007) investigated the distributions of the returns of some financial market indices of the new emerging markets in Eastern Europe after 1991, confirming the stable Paretian hypothesis. Engle (1982) introduced the Autoregressive Conditional Heteroskedasticity (ARCH) model for the variance, and Bollerslev (1987) improved it by generalising the form of the model of the variance and developed the GARCH modelling technique. The present analysis follows these lines. The best fitted models of the returns of the financial market indices of these Eastern European countries are developed and validated, linear trend or ARMA(p,q) for the levels and GARCH(p', q') for the residuals. For risk evaluation financial indicators, the Sharpe-ratio (Gaussian hypothesis), the STARR- and the R-ratio (stable Paretian hypothesis) are calculated.

IC/MP586/013: Backward stochastic differential equations: simulations and applications.

Organiser: Emmanuel Gobet (INP Grenoble, France)

It is known that BSDEs have numerous applications and enable to solve some control problems in a random environment. The aim of this minisymposium is to bring together specialists of BSDEs, with in view different applications in physics, economics or finance.

Sequential Monte-Carlo methods to solve BSDEs. **Céline Labart** (Ecole Polytechnique, France), Emmanuel Gobet (INP Grenoble, France) IC/MT4356/013

Since 1990, the theory of BSDEs has been widely developed and it gives an alternative way to solve semi-linear PDEs. Numerical resolution is still a challenging task. Here we present an iterative approach, combining a Picard iteration and a sequential Monte Carlo approach.

Time discretization and Markovian iteration for coupled FBSDEs. **Christian Bender** (TU Braunschweig, Germany), Jianfeng Zhang (University of Southern California, USA) IC/MT4244/013

In this talk we propose a numerical algorithm to simulate high-dimensional coupled FBSDEs under weak coupling or monotonicity conditions. In particular we derive convergence of a time discretization and a Markovian iteration. The iteration differs from standard Picard iterations for FBSDEs in that the dimension of the underlying Markovian process does not increase with the number of iterations. This feature seems to be indispensable for an efficient iterative scheme from a numerical point of view. We finally suggest a fully explicit numerical algorithm and present some numerical examples with up to 10-dimensional state space.

An interpolated algorithm for quasi-linear PDEs. **Stéphane Menozzi** (University PARIS VII, France) IC/MT4939/088

We propose a time-space discretization scheme for quasi-linear parabolic PDEs. The algorithm relies on the theory of fully coupled Forward-Backward SDEs, which provides an efficient probabilistic representation of this type of equations. The derivated algorithm holds for strong solutions defined on any interval of arbitrary length.
The corner stone of the algorithm is a nonlinear quantized version of the dynamic programming principle. Then, the convergence analysis takes advantage of the standing regularity properties of the true solutionthrough an interpolation procedure and also exploits the optimality of the square Gaussian quantization used to approximate the conditional expectations involved.

In particular, our work provides an alternative to the method described in Douglas, Ma and Protter (Ann. Appl. Prob. 96) and weakens the regularity assumptions required in this reference as well as in the schemes introduced by Milstein and Tretyakov (see Stochastic Numerics for Math. Physics, Springer).

The stopping and starting problem in the model with jumps. **Said Hamadène** (Université Maine Le Mans, France) IC/MT4542/088

In this talk we focus on a real option problem namely the starting and stopping problem (or reversible investment) when the noise is driven by a Brownian motion and an independent Poisson process. This problem is tackled in using the notion of Snell envelope and Backward stochastic differential equations with jumps. We derive a stochastic verification theorem which we show later that is satisfied. When the random noise stems from a standard SDE with jumps we show that the problem is connected with a system of two variational inequalities. We finally give some numerical examples.

IC/MP115/008: Stochastic numerics: Monte-Carlo methods, SDEs, PDEs.

Organiser: Wesley Petersen (ETH Zürich, Switzerland)
Co-organiser: Michael Mascagni (Florida State University, USA)

Numerical simulations of stochastic differential equations of the form:

$$dX = b(X)dt + \sigma(X)dW$$

can be generalized to include stochastic partial differential equations (SPDEs) if the dimensionality of the process X is made large enough to resolve the coordinate space discretization. Topics in SDE simulations should include Ito SDEs (e.g. discontinuous drift coefficients), SPDEs, transport equations, high dimensional PDEs, and stochastic functional differential equations (delay equations). Other topics in this double minisymposium will include stochastic methods for potential problems.

Constrained stochastic differential equations in molecular dynamics. **Tony Lelièvre** (École Nationale des Ponts et Chaussées, France) IC/MT3482/088

We present some numerical schemes for SDEs with constraints. Such SDEs appear for example in kinetic modelling (rigid molecular bonds, computations at a fixed reaction coordinate value). After discussing the consistency of various numerical schemes, we more precisely discuss the sampling of Boltzmann-Gibbs measures on a sub-manifold by a gradient dynamics. We explain how such numerical schemes can be used to compute free energy differences in the NVT ensemble, or to sample the NVE ensemble.

Asset pricing in idiosyncratically incomplete markets: a numerical simulation. **Wesley Petersen** (ETH Zürich, Switzerland) IC/MT3512/088

In this ongoing work we consider the weak approximation of reflected Ito diffusions[2] using a projected Euler method. The goal is to compute $E[g(X_T) - \int_0^T h(X_t)\mathrm{d}\xi(t)]$ with a fixed time $T > 0$. This problem is related to the solution of parabolic PDEs with non-homogeneous Neuman boundary condition with value $h(x)$. Our current computations show an improvement in the weak order of convergence from $1/2$ to 1 for the mentioned projected Euler method. The main difficulty comes from approximating local time contributions at the reflection boundary.
Our main inspiration comes from the work[1], where weak order 1 has been achieved for the homogeneous Neuman boundary conditions case using a symmetrized Euler method.

Numerical methods for SDDEs with coloured noise. **Evelyn Buckwar** (TU Berlin, Germany) IC/MT3564/088

We consider stochastic delay differential equations with coloured driving noise. This type of equations appears, for example, in population dynamics. We develop and analyse numerical methods which are especially efficient for this type of equations. Numerical examples illustrate the numerical results.

Recent developments in the scalable parallel random-number generators (SPRNG) library. **Michael Mascagni** (Florida State University, USA), Wesley Petersen (ETH Zürich, Switzerland) IC/MT3653/088

This work presents the new and more versatile Scalable Parallel Random Number Generators Library (SPRNG). SPRNG is a widely used software package for both serial and parallel pseudorandom number generation. Its generators satisfy every known property of good pseudorandom numbers, and have passed some of the most stringent tests for pseudo-randomness available today. The previous versions of SPRNG used C as the implementation language and provided interfaces for FORTRAN and C++. Although SPRNG functions were callable from C++, the concepts of object-oriented programming were not applied in the implementation of earlier versions of SPRNG. In the new version, we replace the implementation language with object oriented C++, while still providing an interface for FORTRAN. Furthermore, we remove SPRNG's dependence on the GNU Multi Precision (GMP) Library and supplant GMP with our own accurate code for arithmetic on arbitrarily large integers and rational numbers. The resulting SPRNG library is as efficient as and complements the previous SPRNG versions and provides a wider user base access to high-quality parallel random number generation.The SPRNG library home page is http://sprng.fsu.edu.

Monte-Carlo methods for problems in biological electrostatics. **Michael Mascagni** (Florida State University, USA) IC/MT3654/088

We have been developing Monte Carlo methods for solving continuum electrostatic problems that arise in biochemistry. In vivo biochemistry takes place in ionic aqueous solution. When a molecule with fixed charges is places in such a solution, the free ions in the solvent reposition themselves accordingly. Accounting for the free ions can be done with explicit solvent models, such as molecular dynamics, or continuum models such as the nonlinear Poisson-Boltzmann equation. Previously we have developed methods for a linearized version of this problem; here we present new results on the full nonlinear Poisson-Boltzmann case.

Stochastic differential equations with discontinuous drift. **Sibylle Arnold** (ETH Zürich, Switzerland) IC/MT3331/008

New weak approximation schemes for SDEs $\mathrm{d}X_t = \mu(X_t)\mathrm{d}t + \sigma(X_t)\mathrm{d}B_t$, where B is a Brownian motion and the coefficients μ and σ are assumed to be only piecewise continuous, are presented. The new methods are based on an Exit problem approach and are shown by a statistical analysis to be superior to the Euler scheme for moderate stepsizes. The approach used for the statistical comparisons can be used in general to judge in a statistically significant way several weak approximation schemes regarding their goodness.

A fully-stochastic version of domain decomposition. **Maire Sylvain** (Université du Sud Toulon-Var, France) IC/MT3941/088

The standard way [1] to combine a deterministic method and the Monte Carlo method for domain decomposition is the following. The domain D is divided into two subdomains D_1 and D_2 separate by an artificial boundary $\Gamma_{1,2}$ An interpolation of the solution on $\Gamma_{1,2}$ is computed based on Monte Carlo approximations at some points of this boundary via the Feynman–Kac formula. Then the solution is computed on each subdomain by means of a deterministic method with the approximation on $\Gamma_{1,2}$ taken as a new boundary condition.The problem of this approach is that the error on the interface $\Gamma_{1,2}$ is usually large except if using a lot of trajectories with a small stepsize in the discretization scheme. We have introduced in [2] a new domain decomposition Monte Carlo algorithm to solve the Poisson equation in a domain D with Dirichlet boundary conditions where this problem is overcomed by using processes of correction and regularization at the interface. In this talk, we describe different strategies to optimize this method and its generalization to multidomain decomposition. Numerical simulations are given in the case of the Poisson equation over hypercubes.

Improving the stability of numerical simulations of quantum dynamical systems using stochastic differential-equation techniques. **Christian Perret** (ETH Zürich, Switzerland) IC/MT4052/088

Quantum dynamical systems typically deal with huge numbers of degrees of freedom, which makes them very difficult to simulate using deterministic methods. Modeling such systems with stochastic differential equations (SDEs) is an attractive option, but there remain stability problems. An example of a multi-dimensional complex SDE arises from an anharmonic oscillator with a one-mode BEC Hamiltonian given in [1], for which the numerical solution becomes unreliable after approximatively $t = 0.3$ for all tested numerical methods. Splitting of drift methods as introduced in [2] have been tried on this problem and improved the stability of the results, but not to the desired extent.

To improve the results, new numerical splitting methods have recently been developed. However, it seems that the choice of the numerical scheme alone might not guarantee the reliability of the results. The use of carefully chosen stochastic gauges as in [1] improves the accuracy of the simulation considerably by taking into account some aspects of the dynamics of the system, but so far the choices of gauges lead to a dissipative behavior of the diffusion part. The results using various techniques will be discussed.

IC/MP163/015: Probabilities meet scientific computing.

Organiser: Laurent Demanet (California Institute of Technology, USA)
Co-organiser: Lexing Ying (University of Texas at Austin, USA)

This workshop will overview recent research directions where probabilities help in designing efficient algorithms for intrinsically deterministic problems.

1) A first approach consists in randomly sampling rows and columns of a matrix, or apply the matrix to random vectors, in order to speed up the computation of low-rank approximations, like truncated SVD.
2) A second approach known as compressive sampling, or compressed sensing, consists in observing a signal in a *noise* basis in order to reconstruct it as a sparse superposition in another basis, by means of convex optimization techniques.
3) A third approach consists in modeling uncertainty about physical parameters through randomness, and solving for expectations and moments. This applies for instance to waves in random media.

Computational methods for waves in random media. **George Papanicolaou** (Stanford University, USA) IC/MT3209/015

The numerical simulation of wave propagation in random media is a challenge not only because we are typically interested in long distance propagation in media with inhomogeneities on many scales, but also because the usual notions of accuracy and computational complexity in the numerical solution of differential equations are not quite the right ones. The point is that since we model the medium by a random process, we do not know it in detail. We only know it statistically. In simulating wave propagation in such a medium we similarly do not want the waves calculated in all details, with numerical accu-

racy. We only want to compute them so that they have the correct statistical properties over long distances, and, if possible, with a simple method. I will address this problem and describe several methods that work well in different random media.

A randomized algorithm for the approximation of matrices. **Per-Gunnar Martinsson** (University of Colorado at Boulder, USA) IC/MT3210/015

In this talk, we will describe a randomized procedure for computing low-rank approximations to a given matrix. Specifically, suppose that we are given an $m \times n$ matrix A and a positive integer k, and that we seek to determine a matrix Z of rank k that approximates A (the matrix Z may be, *e.g.* a partial QR decomposition, or a partial singular value decomposition). The procedure that we propose solves the task by applying A and/or A^{t} to a sequence of l random vectors; it is particularly efficient whenever A or A^{t} can rapidly be applied to vectors (as happens, *e.g.*, when A is sparse, or is associated with the discretization of an integral operator). If l is only slightly larger than k, then the discrepancy between A and Z will be of the same order of magnitude as the $(k+1)^{\mathrm{st}}$ singular value σ_{k+1} of A with negligible probability of even moderately large deviations. As an example, we have proved that if $l = k + 20$, then the likelihood that the spectral norm $||A - Z||$ is greater than $10\sqrt{m(k+20)}\ \sigma_{k+1}$ is less than 10^{-17}.

We will describe applications of the scheme to numerical linear algebra, to signal processing, and to the design of fast algorithms for applying and inverting integral operators. We will also discuss techniques for how to adaptively determine the numerical rank of a given matrix. Several computational examples will be presented.

This is work done in collaboration with Vladimir Rokhlin and Mark Tygert.

Randomized algorithms for matrices, learning, optimization, and data. **Michael Mahoney** (Yahoo Research, USA) IC/MT3732/089

Much recent work in theoretical computer science, numerical linear algebra, machine learning, and statistical data analysis has exploited randomness as a computational resource to develop algorithms that provable approximate the solution to common matrix operations. Applications of such algorithms include the computation of low-rank matrix approximations qualitatively faster than traditional methods, sparsity-preservation in low-rank matrix approximations, speeding up kernel-based statistical learning, the efficient computation of coresets for common regression and optimization problems, and the improved scalability and interpretability of data analysis methods. We will describe recent algorithmic developments, with an emphasis on algorithms with provable *a priori* quality-of-approximation bounds. We will also discuss recent applications of this work to the scalable analysis of very large scientific and internet data sets.

Fast computation of Fourier integral operators. **Emmanuel Candès** (California Institute of Technology, USA), Lexing Ying (University of Texas at Austin, USA), Laurent Demanet (California Institute of Technology, USA) IC/MT4228/089

This talk introduces an efficient and novel algorithm for the numerical evaluation of Fourier integral operators (FIOs). This is of interest because FIOs are very important kinds of highly oscillatory integrals connected with wave propagation and which come up in a large number of applications. Examples in reflection seismology, radar imaging, ultrasound imaging, and electron microscopy all come to mind. Because an FIO is a dense matrix, a naive matrix vector product with an input given on a Cartesian grid of size N by N would require $O(N^4)$ operations. In contrast, our approach requires $O(N^{2.5}\log N)$ operations and as low as $O(N^{.5})$ in storage space (in practice, the constants are small). In numerical tests, the speedup factor over the naive evaluation for grids of size 512 by 512 is close to 200.

The algorithm operates by localizing the integral over polar wedges with small angular aperture in the frequency plane. On each wedge, the algorithm factorizes the highly oscillatory kernel into two components: 1) a diffeomorphism which is handled by means of a nonuniform FFT and 2) a residual factor which is handled by numerical separation of the spatial and frequency variables. In some sense, the algorithm can be seen as a generalization of the FFT for inhomogeneous phases and amplitudes. We also demonstrate the numerical accuracy and low computational complexity of the proposed methodology.

This is joint work with Laurent Demanet and Lexing Ying.

Optimal sequential decision-rules with restrictions. **Vadim Arkin** (Russian Academy of Sciences, Moscow) IC/CT957/010

We obtain necessary and sufficient optimality conditions for general stopping problems with terminal decisions and integral restrictions. These problems are connected with sequential analysis and some aspects of financial mathematics. In particular, for the case of several hypotheses about the observable process the problem under discussion can be reduced to Bayesian one with Lagrangian as a risk function.

Let $(\Omega, \mathcal{F}_t, \mathcal{F}, \mathbf{P})$ be a standard stochastic basis, $\mathcal{P}$ be a σ-algebra of progressively measurable sets, and $\mathcal{M}$ be a class of stopping times respect to $\mathcal{F}_t$. A pair $\delta = (\tau, d_\tau)$ will be called a decision rule if $\tau \in \mathcal{M}$, and d_τ be $\mathcal{F}_\tau$-measurable function with values in a complete separable metric space $(D, \mathcal{D})$.

Let $\mathcal{D} \times \mathcal{P}$-measurable functions $\varphi_0(d,t,\omega), \ldots, \varphi_n(d,t,\omega)$ and non-empty set $Q \in \mathcal{D}$ are given. Consider the following extremal problem:

$$\Phi_0(\delta) = \mathbf{E}\,\varphi_0(d_\tau, \tau) \to \max_\delta,$$
$$\Phi_i(\delta) = \mathbf{E}\,\varphi_i(d_\tau, \tau) \le 0, \quad i = \overline{1,n}, \quad d_\tau(\omega) \in Q,\ \mathbf{P}-\text{a.s.}$$

Denote $H(d,\tau) = \varphi_0(d,\tau) - \sum_{i=1}^n \Lambda_i \varphi_i(d,\tau)$.

Theorem *Let σ-algebra $\mathcal{F}_0$ does not contain $\mathbf{P}$-atoms, $\Phi_0(\delta^*) < \infty$, and there exists $\hat{\delta}$ such that $\Phi_i(\hat{\delta}) < 0$, $i = \overline{1,n}$. Then decision rule $\delta^* = (\tau^*, d^*_{\tau^*})$ be optimal if and only if there exist values $\Lambda_i \ge 0$, $i = \overline{1,n}$ such that*

1. $\tau^* = \operatorname{argmax}_{\tau \in \mathcal{M}} \mathbf{E} \sup_{d \in Q} H(d,\tau)$;
2. $d^*_{\tau^*} = \operatorname{argmax}_{d \in Q} H(d, \tau^*) \quad (\mathbf{P}-a.s.)$,
3. $\sum_{i=1}^n \Lambda_i \mathbf{E}\,\varphi_i(d^*_{\tau^*}, \tau^*) = 0$.

Multivariate Poisson summation formula applied to estimation of closeness to the uniform distribution. **Vladimir Khokhlov** (Steklov Mathematical Institute, Russian Federation) IC/CT506/010

A probabilistic interpretation of the multivariate Poisson summation formula (PSF) gives a way to estimate the deviation $\Delta = \sup_{\mathbf{x}_{(s)}\in[0,1]^s} |\, p\,(\mathbf{x}_{(s)};\{\mathbf{X}_{(s)}\}) - 1\,|$ of the density $p\,(\mathbf{x}_{(s)};\{\mathbf{X}_{(s)}\})$ of the distribution of a random vector $\{\mathbf{X}_{(s)}\}$ consisting of components which are fractional parts of components of a random s-dimensional vector $\mathbf{X}_{(s)}$ in $\mathbb{R}^s$ from the density of the uniform distribution in the unit s-dimensional cube $[0,\,1]^s$ in $\mathbb{R}^s$.

Under some conditions which make it possible to apply PSF, we get the upper bound $\Delta = \sup_{\mathbf{x}_{(16)}\in[0,1]^{16}} |\, p\,(\mathbf{x}_{(16)};\{\eta\,\mathbf{Z}_{(16)}\}) - 1\,| \;\le\; \dfrac{P(q)}{(1-q)^8}$ for the vector $\{\eta\,\mathbf{Z}_{(16)}\}$ of fractional parts of the random Gaussian vector $\eta\,\mathbf{Z}_{(16)}$ having a nonsingular covariance matrix; $P(q)$ is a polynomial of the seventh degree of $q = e^{-2\pi^2\eta^2\lambda}$; where $\eta > 0$ is an arbitrary scaling parameter, which may increase infinitely in applications, and $\lambda > 0$ is the minimal eigenvalue of the covariance matrix. The proof is based on the upper bound for the number $r_{16}(N)$ of integer points $\mathbf{m}_{(16)} = (m_1, m_2, \ldots, m_{16}), m_\nu \in \mathbb{Z}$, lying on the 16-dimensional sphere $S_{16}(\sqrt{N})$, for $N \in \mathbb{Z}^+$. The approach can be extended to higher dimensions s, being a multiple of 16 (see[1]).

[1] Khokhlov, V.I.; A method of estimation of the number of integer points on the multidimensional sphere and its application to the problem of estimation of closeness to the uniform distribution. Obozr. Prikl. Prom. Mat. **13** (2006), pp.3–27.

Asymptotics of the log*-partition function and new algorithms for counting without sampling.* **Antar Bandyopadhyay** (Indian Statistical Institute (Delhi Centre)), David Gamarnik (Massachusetts Institute of Technology, USA) IC/CT4327/082

In this talk we will propose new methods for computing the asymptotic value for the logarithm of the partition function for certain statistical physics models on certain type of finite graphs, as the size of the underlying graph goes to infinity. We will consider two models, namely the *hard-core* model when the *activity* parameter λ is *small*, and the model for counting the number of proper q-colorings. And we will only consider the graphs with *large girth*. In particular, we will show that asymptotically the logarithm of the number of *independent sets* of any r-regular graph with large girth is constant, when $r \le 5$. For example, we will show that every 4-regular n-node graph with large girth has approximately $(1.494...)^n$-many independent sets, for large n. Similarly we will prove that for every r-regular graph with $r \ge 2$, with n nodes and large girth, the number of proper $q \ge r+1$ colorings is approximately a constant (which can be explicitly written in terms of q and r), when n is large. Similar results also hold for random regular graphs. As a byproduct of our method we will show that one can obtain some simple approximate counting algorithms for the problem of enumerating the number of independent sets, and proper colorings, in low degree graphs with large girth. These algorithms will be deterministic as opposed to Markov chain sampling schemes which are typically used in this context. Our main approach will be to use a (strong) *correlation decay* property for the corresponding Gibbs measure (at certain parameter regime), along with a simple *cavity trick* which is well known in the physics literature.

Time-series modelling of the Singapore population data. **Wai Kwong Cheang** (Nanyang Technological University, Singapore) IC/CT1813/085

Trends in population have important implications for a government in formulating its manpower-related policies. A business may also need to adjust its long-term market strategies according to these trends. This paper analyses the Singapore population data using time series regression model with autoregressive error term. In addition to a linear trend, other regressors included in the model are (i) a seasonal component of period 12 to account for the effect of the auspicious "dragon" years in the Chinese calendar; (ii) level-shift interventions to account for the effect of the government campaigns on family planning. Two methods of estimating the autoregressive parameter are considered: maximum likelihood (ML) and restricted maximum likelihood (REML). For a time series of short or moderate sample length, it is shown in Cheang and Reinsel (2000) [Bias reduction of autoregressive estimates in time series regression model through restricted maximum likelihood, Journal of the American Statistical Association, 95, 1173–1184] that the REML estimator is generally much less biased than the ML estimator. This paper compares the ML and REML estimation results, and examines the implications for the nature of nonstationarity (deterministic or stochastic trend component) exhibited by the Singapore population data series.

Prediction of bond ratings using statistical and neural network techniques. **Shariful Alam** (Department of Mathematics, Bengal Engineering and, India) IC/CT4243/008

Quantitative models have been developed to predict bond ratings of firms in the Indian Manufacturing Sector, using Financial Leverage, Profitability, Asset Management Ability, Stability and Market Sensitivity of the firm, which totally involved 16 variables. These 16 independent variables are first reduced to seven orthogonal variables using Principal Component Analysis. Then these variables are used to build three types of quantitative models namely Multiple Discriminant Analysis (MDA) model, Multinomial Logistic Regression (MLR) model and Artificial Neural Networks (ANN) model.

MDA models are developed using two approaches, viz., FisherŠs Discriminant Analysis (FDA) and Discriminant Analysis by MLE method [Quadratic Discriminant Analysis (QDA)]. Comparison is made between FDA and QDA models and it is found that QDA model is superior to FDA model. In MLR attempts have been made to build proportional odds model and subsequently conventional full multinomial logit model. It is found that the proportionality of odds is violated and an appropriate multinomial logit model is proposed. In ANN a feed forward neural network with one hidden layer is chosen for analysis. Network size and geometry is finalized after experimenting with 5 logically built networks. Levenberg-Marquardt BP algorithm is used as the training algorithm and MSE (mean squared error) is used as network performance function during training. After some trial and error, Tan-Sigmoid (tansin) is used in the hidden node and Log-Sigmoid (logsin) is used in the output node as activation functions.

Based on both in-sample classification and out-sample validation it is found that both MLR and ANN models are superior to MDA, with little difference in performance between themselves.

On the stability of some stochastic integral equation. **Khairia El-Nadi** (Alexandria University, Egypt) IC/CT24/010

Stochastic Volterra equations of the form:

$$dx(t) = f(x(t))dt + \int_0^t K(t-s)x(s)ds\;dt + g(x(t))dB(t),$$

are considered, where $\{B(t) : t \ge 0\}$ is standard one-dimensional Brownian motion and the kernel K decreases to zero non-exponentially. We study the convergence rate to zero of the stochastic solutions of the considered equation. It is

proved under suitable conditions that :

$$\lim_{t\to\infty} \frac{|x(t)|}{K(t)} = \infty, \quad \text{almost surely.}$$

The considered stochastic integral equations arise if we consider the Black–Scholes market consists of a Bank account or a bond and a stock. These stochastic models can also be applied to population dynamics in biology.

Reliability enhancement and fixed transmission times of acyclic transmission multiŰstate networks (ATMNs). **Sanjay Chaudhary** (Ambedkar University, Agra, India) IC/CT761/010

In this talk, an algorithm for acyclic transmission multi-state networks (ATMNs) is suggested in which each network has a root position where the signal source is located, a number of leaf (terminal) nodes that can only receive the signal, and a number of non-leaf (non-terminal) nodes that retransmit the received signal to some other nodes. The signal propagation from root node to terminal nodes, which avoid the cycle. The time of the signal transmission between each pair of nodes in ATMNs depends on the type of equipment and exchange protocols. Two types of networks are considered in which one type network has individual multi-state elements (MEs) located at different positions. Second type networks have two MEs located at same position and other MEs located at different positions individually. The universal generating function technique is applied in ATMNs for evaluating the system reliability and expected value in specified time.

On a queueing system that exhibits Markovian character due to service interruptions. **A Krishnamoorthy Krishnamoorthy** (Cochin University, India) IC/CT2829/082

We consider a service system which exhibits a kind of Markovian property momentarily if and when the Markovian property is revealed due to a service interruption, the service is repeated. On the other hand if the service interruption does not result in the realization of the Markovian property, the current service is resumed. We analyse the system under very general assumptions on interarrival, service time and repair time (due to interruption) distributions. These are assumed to be independent of each other. Several performance measures are obtained. Some numerical results are provided. This model finds applications in medicine, in certain manufacturing processes with interruption, and certain learning processes.

Risk-constrained scheduling of electricity markets. **Arash Ehsani** (Islamic Azad University, Iran), AliMohammad Ranjbar (Sharif University of Technology, Iran), Mahmud Fotuhi-Firuzabad (Sharif University of Technology, Iran) IC/CT2842/008

Electricity markets are typically operated at least cost subject to technical constraints. This paper presents a probabilistic model for competitive electricity markets. A competitive structure is proposed which includes a purchasing agency with centrally optimized scheduling. Supply reserve is considered in the proposed approach. The value of risk is deduced from the supply model. The required supply model is constructed using the outage replacement rate (ORR) of energy production units. On demand side, the consumption forecast uncertainty is included. The performance of the proposed method is verified through numerical case studies.

Complete coverage and eventual coverage of space by random sets. **Anish Sarkar** (ISI Delhi, India) IC/CT1408/082

We consider of a point process on S on a subset of $\mathbb{R}^d$ for $d \geq 1$. With each point of the point process, we associate a random shape (we consider only sphere with i.i.d. radius and squares with i.i.d. side lengths here). Let C be the random region covered by these random shapes. We are interested in some coverage properties of this random set C. If $S = \mathbb{R}^d$, the main question that one asks, is about complete coverage; i.e., under what conditions is $C = \mathbb{R}^d$? (see Hall [1988] and Meester & Roy [1996]). Athreya et. al. [2004] introduced the notion of eventually coverage, where they studied the properties of C when $S = (0,\infty)^d$ when the underlying point process is a homogeneous Poisson process in $d = 1$ or $d \geq 2$. We extend these concepts for the half-spaces and study the eventual coverage of certain unbounded sets of the half-space. We show that the eventual coverage depends on the tail behaviour of the radius random variable.

An SDP relaxation of the sparsest recovery problem. **Stephane Chretien** (Université de Franche-Comté, France) IC/CT3182/088

The problem of recovery of the sparsest solutions to overdetermined linear systems of equations has recently been addressed by several authors starting with Candès, Romberg and Tao [E. J. Candès, J. Romberg and T. Tao (2004). Robust Uncertainty Principles: Exact Signal Reconstruction from Highly Incomplete Frequency Information, IEEE Inf. Theory 52 (2006) Vol 2., 489–509]. This problem is of great theoretical as well as practical importance. Indeed, looking for sparse representation of information is a new way to look at various fields such as modern harmonic analysis, numerical approaches to PDE and statistics with wide ranging scope of applications.

One of the breaktroughs in the work of Candes, Romberg and Tao was the realization that the $\mathcal{NP}$-hard optimization problem of finding the sparsest solution to overdetermined linear systems of equation can be solved with high probability using linear programming (LP) via a simple substitution of the sparsity objective function with values in $\mathbb{N}$ with the l_1 norm of the vector to be optimized. Formally, for any vector $x \in \mathbb{N}$, let $\|x\|_0$ denote the number of nonzero components of x and let $\|x\|_1$ denote its l_1 norm that is the sum of the absolute values of its components. The problem of finding the sparsest solution to the system

$$Ax = b \tag{1}$$

with A in $\mathbb{R}^{m\times n}$, b in $\mathbb{R}^m$ and m much smaller that n can be written as the following optimization problem

$$\min_{x\in\mathbb{R}^n} \|x\|_0 \text{ s.t. } Ax = b. \tag{2}$$

The convex relaxation is given by

$$\min_{x\in\mathbb{R}^n} \|x\|_1 \text{ s.t. } Ax = b \tag{3}$$

and can easily transformed into a linear program.

The goal of this paper is to present a stronger convex relaxation using semidefinite programming (SDP) for which efficient interior point method have been designed and various packages exist such as SeDuMi for Matlab. This class of convex optimization problems has been the subject of an intense research activity in the nonlinear optimization community, leading to efficient polynomial time algorithms for various difficult problems in combinatorics and engineering; see for instance [Nemirovski, A. Advances in Convex Optimization: Conic Programming - to appear in Volume I (Plenary Lectures) of International Congress of Mathematicians, Madrid 2006, European Mathematical Society, 2006].

The strengthened relaxation we propose is obtained as follows. Introduce the vector $z \in \mathbb{R}^n$ of 0-1 variables. This vector will index the components of x which should be set to zero through the constraint

$$z^t x = 0 \tag{4}$$

Now the cost function is given by $\sum_{i=1}^{n} z_i$ which is exactly the number of components of x equal to zero. The constraints specifying the binary nature of z are of the form

$$z_i(z_i - 1) = 0 \text{ for } i = 1, \ldots, n. \tag{5}$$

To sum up, we obtain a new representation of the sparsest recovery problem, given in the form of a quadratically constrained nonconvex optimization problem as

$$\begin{array}{l} \max_{x,z \in \mathbb{R}^n} e^t z \\ texts.t. \left\{ z_i(z_i - 1) = 0, \quad i = 1, \ldots, n \quad z_i x_i = 0, \quad i = 1, \ldots, n \quad Ax = b. \right. \end{array} \tag{6}$$

As is well known in the optimization community, the class of quadratically constrained quadratic programs to which this problem belongs, admits SDP relaxations. SDP are convex optimization problems over the cone of positive semidefinite matrices in the set of real symmetric matrices. This relaxation can be obtained in a systematic manner using Lagrangian duality, leading in the present case to a problem of the form

$$\begin{array}{l} \max_{X \in \mathbb{S}_{2n+1}} \operatorname{trace}(A_0 X) \\ texts.t. \left\{ \operatorname{trace}(A_j X) = c_j, \quad i = 1, \ldots, m + 2n + 1 \quad X \succeq 0. \right. \end{array} \tag{7}$$

where $\mathbb{S}_n$ is the set of real symmetric matrices of order n and $A \succeq B$ is the order relation generated by the cone of positive semidefinite matrices.

We will show in particular that this relaxation is stronger than the previous one and provide simulations results proving the applicability of this new approach.

Scale's descriptions, system's approach to risks. **Natalia Serdyukova** (Academy of Budget and Treasury, Russian Federation) IC/CT4811/071

Full classification of all types of scales is obtained in terms of group of admissible transformations of scale. Matrix, lattice, and multidimensional scales are introduced. It is proved that twodimensional scales are the most informative. Lump-sum function of risk is defined in probability space as dual function to probability measure. Owing to common dual theory constructed function repels the most common typical behaviour of risk. Some wellknown measuring instruments, such as generalize dispersion satisfy to proposed scheme.

Investigation of properties of the solutions of hyperbolic SPDE. **Oleksiy Ignatyev** (Institute of Apllied Mathematics and Mechanics of, Ukraine) IC/CT709/082

We consider the space-time white noise-driven stochastic partial differential equation (SPDE) on $R_T = [0,T] \times [0,+\infty)$.

$$\frac{\partial^2 u(t,x)}{\partial t \partial x} = u^{\alpha}(t,x) \quad \frac{\partial^2 W(t,x)}{\partial t \partial x}$$

$$u(0,x) = \tilde{u}(x), \qquad u(t,0) = p(t)$$

where $T > 0$ is fixed but arbitrary. $W(t,x)$ is the Brownian sheet corresponding to the driving space-time white noise-with intensity Lebesgue measure-written formally as $\partial^2 W / \partial t \partial x$. The functions $\tilde{u}(x)$ and $p(t)$ are taken to be continuous bounded deterministic functions.

In this paper we investigate whether the solution $u(t,x)$ of the above hyperbolic SPDE has compact support property for all $t > 0$ providing that $\tilde{u}(x)$ has compact support property.

Branching principal components, principal cubic complexes and topological grammars. **Alexander Gorban** (University of Leicester, UK), Andrei Zinovyev (Institut Curie, France), Neil Sumner (University of Leicester, UK) IC/CT1269/087

A method of topological grammars is proposed for multidimensional data approximation. For data with complex topology we define a principal cubic complex of low dimension and given complexity that gives the best approximation for the dataset. This complex is a generalization of linear and non-linear principal manifolds and includes them as a particular case. The problem of optimal principal complex construction is transformed into a series of minimization problems for quadratic functionals. These quadratic functionals have a physically transparent interpretation in terms of elastic energy. For the energy computation, the whole complex is presented as a system of nodes and springs. Topologically, the principal complex is a product of one-dimensional continuums (represented by graphs), and the graph grammar [1] describes transformation of these factors during construction of the optimal complex. This factorization of the whole process onto one-dimensional transformations and using minimization of quadratic energy functionals allow us to construct efficient algorithms. The topology of the complex is not prescribed, but adaptive. In that sense, they are even more flexible than SOMs [2]. The whole approach can be interpreted as an intermediate between very flexible neural gas and significantly more restrictive elastic maps [3]. It includes as simple limit cases the k-means clustering algorithm, classical PCA and Principal manifolds [4].

Stable computation of probability densities for metastable dynamical systems. **Susanna Kube** (Zuse-Institut Berlin, Germany), Marcus Weber (Zuse-Institut Berlin, Germany), Peter Deuflhard (Zuse-Institut Berlin, Germany) IC/CT3976/088

Whenever the invariant stationary density of metastable dynamical systems decomposes into almost invariant partial densities, its computation as eigenvector of some transition probability matrix is an ill-conditioned problem. In order to avoid this computational difficulty, we suggest to apply an aggregation/disaggregation method which only addresses well-conditioned sub-problems and thus results in a stable algorithm. In contrast to existing methods, the aggregation step is done via a sampling algorithm which covers only small patches of the sampling space. We will show how this method allows the correct computation of statistical weights for molecular conformations.

Weak predictor–corrector schemes for jump diffusions. **Nicola Bruti Liberati** (University of Technology, Sydney, Australia), Eckhard Platen (University of Technology, Sydney, Australia) IC/CT714/088

Event-driven uncertainties such as corporate defaults, operational failures or central bank announcements are important elements in the modelling of financial quantities. Therefore, stochastic differential equations (SDEs) of jump-diffusion type are often used in finance. We consider in this paper weak discrete time approximations of jump-diffusion SDEs which are appropriate for problems such as the evaluation of moments, derivative prices, risk measures and expected utilities. We present regular and jump-adapted predictor-corrector schemes with first and second order of weak convergence. The regular schemes are constructed on time discretizations that do not include jump times, while the jump-adapted schemes are based on time discretizations that include all jump times. Finally, we test the accuracy of these schemes when applied to the jump-diffusion Merton model.

Bivariate geometric models and their applications. **Jayakumar Kuttan Pillai** (University of Calicut, India) IC/CT2858/008

Geometric distribution possess lack of memory property and is applied in a variety of contexts. Characterizations of a bivariate geometric distribution using univariate and bivariate geometric compounding are obtained. Autoregressive models with marginals as bivariate geometric distribution are developed. Various bivariate geometric models analogous to important bivariate exponential distributions like, Marshall–Olkin bivariate exponential, Downton's bivariate exponential and Hawkes' bivariate exponential are introduced and studied.

Discrete Mittag–Leffler distribution is a class of distributions containing geometric distribution. Discrete Mittag–Leffler distribution is infinitely divisible and is normally attracted to stable law. In this paper various bivariate discrete Mittag–Leffler models are introduced. Various characterizations of discrete Mittag–Leffler distributions are obtained through closure under geometric summation and repeated geometric summation. Time sreies models with bivariate discrete Mittag–Leffler marginals are developed and their properties are studied.

Key words:- Autoregressive process, Bivariate exponential distribution, Bivariate geometric distribution, Characterization, Compounding.

Some results on generalised probability-distribution functions. **Rajendra Kumbhat** (Jai Narain Vyas University, India), Shanu Sharma (Jodhpur, India) IC/CT3251/010

In this paper a generalised probability distribution function has been introduced using generalised hypergeometric function 2R1(.) from which almost all classical probability distribution functions defined earlier can be obtained as special cases.For the probability distribution function,the moment generating function,moments and the characterstic functions have been investigated.The distribution of linear combination of independent variables has also been worked out. Kindly acknowledge the receipt.

On the accuracy of the normal approximation to the distributions of Poisson random sums. **Irina Shevtsova** (Moscow State University, Russian Federation) IC/CT1097/010

Let $X_1, X_2, \ldots$ be a sequence of independent identically distributed random variables with finite moments of order $2+\delta$ with some $\delta \in (0,\,1]$ and N_λ be a Poisson random variable with parameter $\lambda > 0$, independent of $X_1, X_2, \ldots$ for each $\lambda > 0$. Denote $F_\lambda(x)$ the distribution function of the standardized Poisson random sum $X_1 + \ldots + X_{N_\lambda}$ and $\Phi(x)$ the standard normal distribution function. We show that under above assumptions the following analogue of the Berry–Esseen inequality holds:

$$\rho(F_\lambda,\,\Phi) \equiv \sup_x |F_\lambda(x) - \Phi(x)| \le \begin{cases} C(\delta)\cdot L_\lambda^{2+\delta}, & \text{for } 0<\delta<1, \\ 0.7056\cdot L_\lambda^3, & \text{for } \delta = 1, \end{cases}$$

where $L_\lambda^{2+\delta}$ is the noncentral Lyapunov fraction and

$$C(\delta) = \frac{2^{1-\delta/2}\Gamma(\frac{2+\delta}{2})}{\pi(1+\delta)(2+\delta)}.$$

As it can easily be seen, the function $C(\delta)$ monotonically decreases varying within the range $(6\sqrt{2\pi})^{-1} = C(1-) \le C(\delta) \le C(0+) = \pi^{-1}$.

We also show that for $\delta = 1$ under additional assumption of integrability of the characteristic function of the random summands the following refined estimate holds:

$$\rho(F_\lambda,\Phi) \le \frac{L_\lambda^3}{6\sqrt{2\pi}} + O\Big(\frac{\sqrt{\ln\lambda}}{\lambda}\Big),$$

given an explicit expression for the latest term.

Correcting the Monte-Carlo optimal-stopping bias. **Tyson Whitehead** (University of Western Ontario, Canada), Matt Davison (University of Western Ontario, Canada), Mark Reesor (University of Western Ontario, Canada) IC/CT4512/086

Optimal-stopping problems are frequently solved by approximating them as discrete optimal-stopping problems, and then applying Bellman's principle to break them up into a series of sub-problems to be solved via Monte Carlo and then optimally recombined. The problem with this is that, while each sub-problem may be evaluated in a non-biased manner, the process of recombination favours those sub-problems whose value has been overestimated, introducing solution bias. We present an overview of our asymptotic work showing how to derive a first-order correction term for this effect. We also present the results of applying such a correction term to the stochastic-mesh technique in a financial example, a well-studied multivariate pricing problem, which demonstrates the resulting significant computational advantage.

Stochastic homogenization on self-similar structures. **Anna Soos** (Universitatea Babeş-Bolyai, Romania) IC/CT908/082

The homogenization theory is devoted to analysis of partial differential equations with rapidly oscillating coefficients. Let $\mathcal{A}^k$ be a given partial differential operator and we consider the equation $\mathcal{A}^k u^k = f$, together with the appropriate boundary initial conditions. Here $k \in \mathbb{N}$ and $f \in H^1(\mathbb{R}^n)$. We are interested in studying the solutions of this system in the limit as $k \to \infty$. The homogenization theory study the convergence of u^k, as $k \to \infty$, characterize the limiting process and construct the limiting equation. In this article we will quit the periodicity assumption. The coefficients are generated by an iterated function system. We will give a new kind of homogenization method on selfsimilar structures. We will use some basic notions from the fractal geometry as the invariant set and invariant measure of an iterating function systems.

The economic impact of obesity on automobile fuel consumption in the United States. **Sheldon Jacobson** (Univ. of Illinois at Urbana-Champaign, USA) IC/CT2484/010

Obesity has become a major public health problem in the United States. There are numerous health implications and risks associated with obesity. One socio-economic implication of obesity is that it reduces passenger vehicle fuel economy (i.e., the miles per gallon achieved by automobiles, which include cars and light trucks driven for noncommercial purposes). This paper quantifies the amount of additional fuel consumed (annually) in the United States by automobiles that is attributable to higher average passenger (driver and non-driver) weights, during the period from 1960 to 2002. The analysis uses existing driving data in conjunction with historical weight data. The results indicate that, since 1988, no less than 272 million additional gallons of fuel are consumed annually due to average passenger weight increases. This number grows to approximately 938 million gallons of fuel when measured from 1960, which corresponds to approximately 0.7% of the nation's annual fuel consumption, or almost three days of fuel consumption by automobiles. Moreover, more than 39 million gallons of fuel are estimated to be used annually for each additional pound of average passenger weight. This research is co-authored with Laura A. McLay.

A stochastic interpretation of the Mumford–Shah functional. **Tapio Helin** (Teknillinen Korkeakoulu, Finland) IC/CT2710/085

Inverse problems are related to solving quantities that cannot be measured directly. A typical property of inverse problems is their ill-posedness. In Bayesian inversion theory the problem is formulated as a statistical inference problem based on stochastic models of indirect measurements and *a priori* information. In this setting the solution is the posterior probability distribution.

In 1989 Mumford and Shah proposed their celebrated minimization method for image segmentation. The method combines shape and functional minimization thus making the computational problem challenging.

In this talk we discuss the connections between the Mumford-Shah –functional and the Bayesian approach in statistical inverse problems.

This work has been done in collabration with Professor Matti Lassas, Helsinki University of Technology, Finland.

Symbolic–numeric algorithms for analysis of stochastic systems with different forms of after-effect. **Igor Poloskov** (Perm State University, Russian Federation) IC/CT783/088

An analysis of random phenomena in dynamic systems of various types is a very important subject both for theory and practice. The necessity of such analysis is urgent for study of different events: (i) a flight of vehicles under an action of atmospheric turbulence; (ii) a traffic along a rough road; (iii) high-altitude vibrations of structures under wind and seismic attacks etc.

Effects of delay in different forms occur in a lot of tasks. Such phenomena appear, where features of objects are defined by an action of aftereffect, for example there are processes of automatic control for technical devices and engineering procedures, economic and social systems, struggle of species for existence in biology and so forth.

The main idea of our technique for stochastic differential equations with single and multiple, constant and variable delays is to expand the phase space of appropriate system and to reduce a non-Markovian vector process to a Markovian one. By this way we construct:

– chains of Fokker-Planck-Kolmogorov-like equations satisfied by the (transitional) probability density functions for vectors belonging to a family of embedded phase spaces;

– chains of equations for moments of these vectors.

Further we define a number of stochastic cases for a classic method of steps and demonstrate an exploitation of the cumulant closure for nonlinear systems at a stage of numerical calculations on the base of our Mathematica-code package ProbRel.

The idea of the phase extension is used for study of linear stochastic integro-differential equations with additive and multiplicative noises.

The techniques are applied to study a number of linear and nonlinear models such as linear equations of car motion effected by front-to-rear delay and a rough road; dynamics of pollutions discharged into a cascade of natural water bodies; a nonlinear system with multiple delays; a Black-Scholes model with a constant delay and Wiener and Poisson random excitations etc.

Spherical codes: separation, discrepancy and energy. **Paul Leopardi** (Australian National University) IC/CT1125/088

On the unit sphere $S^d \in \mathbb{R}^{d+1}$, a construction is given for a spherical code called the EQ code. The sequence of EQ codes is well separated.

For $0 < s < d$ a sequence of S^d codes which is well separated and weak star convergent has a Riesz s energy which converges to the corresponding energy double integral. A bound is given on the rate of convergence of Riesz s energy given the rate of convergence to zero of the spherical cap discrepancy.

Estimates are given for the rate of convergence to zero of the spherical cap discrepancy of the EQ codes, and the rate of convergence of the Riesz s energy of the EQ codes to the energy double integral.

Stochastic model for fiber lay-down process in non-woven production. **Nicole Marheineke** (TU Kaiserslautern, Germany) IC/CT4016/008

In this work a stochastic model for the lay-down of fibers on a conveyor belt in the production process of nonwovens is presented and investigated. The model is based on a stochastic differential equation taking into account the fiber dynamics under the influence of turbulence. A reformulation as a stochastic Hamiltonian system and an application of the stochastic averaging theorem lead to further simplifications of the model. The model is used to compute the distribution of process functionals that might be helpful for the quality assessment of industrial fabrics.

Adaptive detection of distribution changes in a medical information system. **Jack Xue** (Butler Univ. & Conseco Insurance, USA) IC/CT22/010

As a delivery engine of the Regenstrief Medical Recording System (RMRS), the web-based medical document distribution system, Docs4Docs™, is used by thousands physicians in hundreds practices in Indianapolis area to receive laboratory reports, medical transcriptions and patient admission/discharge reports[1]. Docs4Docs collects these critical medical documents as HL7 messages via RMRS and process them into hospital-approved printable format and deliver them to practices' document inbox within a given amount of time. To fulfill the latency requirement, it is critical for Docs4Docs to receive these HL7s in time. Supposing that the latency owing to the HL7 message receiver (receiver, for short) is negligible, the latency in delivery then solely depends on access, transportation and storage of these HL7s along the uploading path.

The Statistical Process Control (SPC) methods, such as p-chart, has been used to monitor the process performance, such as pharmacy expert systems[5]. However, it has been proved that the Sequential Probability Ratio Tests (SPRT), which is the foundation of our algorithm is a superior surveillance tool because it is sensitive not only to disturbances in the signal mean, but also to very subtle changes in the statistical quality (variance, skewness, bias) of signals[4]. Wald[6] proved the optimality of SPRT in case that all random variables in the sequence are independent and identically distributed (i.i.d.) in 1947. Basseville and Nikiforov[7] formulated the fault detection problem as a stochastic dynamic system in 1993. Siegmund and Venkatraman[8] proved the statistical properties of this system in 1995. Lai[9] proposed a framework for multiple hypothesis testing and proved its optimality under a relaxed condition that random variables are the so-called quasi-i.i.d. in 2000.

This paper is to monitor the health of HL7 message receivers as a stochastic process. Assuming that in every time interval, say, $0, \ldots, i$, the number of received HL7s, the signal in study, is independent and normally distributed, with known different means and variances , an (on-line) algorithm for detecting mean and variance drifting faults has been derived. By using historic data learning, and adaptively additives, this algorithm can not only detect a receiverŠs status upward change; i.e., the status change from normal to abnormal, but also the downward edge. To date, the system test has been carried for several months. For all different data feeds, the fault detection for the days of non-holiday is generally satisfactory.

Asset allocation using the Sharpe rule: how to improve an existing portfolio by adding some new assets?. **Kwok Wai Yu** (Hong Kong Polytechnic University) IC/CT4903/088

This paper discusses the applications of the Sharpe rule in portfolio measurement and management. It proposes that a portion of the portfolio value should be invested in some other assets for portfolio improvement. By applying the Sharpe rule, it can be determined that new stocks are worthy of adding to the old portfolio if they satisfy a condition, in which the average return rate of these stocks is greater than the return rate of the old portfolio multiplied by the sum of the elasticity of the VaR and 1. One attraction of our approach is diversification. A numerical example in the Hong Kong stock market is presented for illustration. Consideration is also given to the *optimal* number of new assets to be added in two specific cases (i.e., arithmetic series and geometric series regarding the sequences of expected returns and standard deviations). Some interesting simulation results show that a new portfolio with the *highest* Sharpe ratio can be obtained by adding only a few new asset.

Optimized sums in Leontjev's balance model. **Fatima Askhakova** (Karachaevo-Circassion State University, Russian Federation), Eugene Semenchin (Karachaevo-Circassion State University, Russian Federation) IC/CT4973/081

Leontjev's model of inter-industrial balance is defined as:

$$x = Ax + f, \qquad x \geq \theta, \tag{1}$$

for $x, \theta, f \in R_+^n$, where $R_+^n = \{(x_1, \ldots, x_n) \mid x_i \geq 0, i = 1, 2, \ldots, n\}$, with $A = (a_{ij})$, $i, j = 1, 2, \ldots, n$ being a non-negative matrix of dimension $n \times n$, and θ is the zero vector of dimension n. Here n denotes the number of different branches being analyzed within an economy, and x_i is the volume of output production in the i-th branch. Each a_{ij}, for $i, j = 1, 2, ..., n$, specifies the number of units of the i-th branch that is required for production of one unit of the j-th branch's output, and f is a vector of model's net production. We consider several optimized sums on a multiplicity of determinations.

(1) Maximize the gross production $\sum_{i=1}^{n} x_i$ where the x_i satisfy the Leontjev conditions. This sum measures the general gross production in the economy. It is a linear programming task to maximise it, which can be solved using known methods; e.g., the simplex method.

(2) Maximization of production volume in one or more branches. Consider criteria $x_i \to \max$ with i fixed in $1, 2, ..., n$, or $\sum_{\kappa=1}^{r} x_{i_\kappa} \to \max$, for $r \leq n$. The totality of limitations is given by the Leontjev conditions. These are analysed using balance correlations and inequalities.

(3) Maximization of production volume in several branches, taking into account their preferences. Consider maximis-

ing $\sum_{i=1}^{n} c_i x_i$, with constants satisfying $\sum_{i=1}^{n} c_i = 1$. These coefficients c_i are determined by experts and indicate the preference degree for the i-th branch over other branches.

In the case where the Leontjev model (1) is *productive* (that is, if $\operatorname{rank}(E - A) = \operatorname{rank}(E - A, f) = n$) then the maxima for all the above sums occur together, for a particular solution vector (x_i), though of course the values of the sums themselves differ. A solution of any of the above optimized sums may be assumed as a solution of the model (1) which can be used to determine any of the sums.

However if $\operatorname{rank}(E - A) = \operatorname{rank}(E - A, f) = \kappa < n$ then there can be a great number of distinct solutions for the different optimized sums, and the corresponding solution vectors (x_i) need not coincide. It is permissible to consider the optimized sums on a multiplicity of determinations (1). Solutions of (1) and solutions of the optimized sums can be different.

These results are used to analyze balance models of the economy of the Karachaevo–Circassion Republic.

Organiser: Lukasz Stettner (Polish Academy of Sciences, Poland)

Long-time GOP on markets with transaction costs. **Lukasz Stettner** (Polish Academy of Sciences, Poland) IC/CT1433/081

Growth optimal portfolio (GOP) over long run time horizon is studied for markets with transaction costs. It is assumed that the asset prices (S_t) depend on economical factor process (x_t) and the pair (S_t, x_t) forms a continuous time Feller Markov process. The process (x_t) is uniformly ergodic. The dynamics of S_t is a function of x_t and an independent noise w_t. Portfolio strategy N_t is a vector which consists of numbers of assets we have at time t. For change of portfolio N_t we pay fixed plus proportional transaction costs to the volume of transaction and we assume that portfolio is self financing. Our purpose is to maximize

$$\liminf_{t\to\infty} \frac{1}{t} E\{\log V_t\},$$

where V_t is the value of the portfolio at time t. This kind of problems lead to impulsive control problems with average cost per unit time criterion. This problem in general is open. A special financial setting of the problem allows however to find solutions. In the talk various approaches to this problem will be presented. It will be shown in particular, that the problem can be approximated by discrete time problem, for which we can study suitable Bellman equation or use M. Schall approximation inequality to obtain the existence of optimal portfolio strategies. The key argument used in the talk will be based on large deviation estimates for the pair (x_t, w_t). It is also interesting that the case of proportional transaction costs (without fixed costs) in discrete time is much simpler and the optimal strategies in this case are functions of the portions π_t of the value of portfolio invested in particular assets and factor process (x_t). A few remarks concerning a partially observed case i.e. the case when economic factors (all of a part of them) are unavailable to investor will be also given. Growth optimal portfolio is important since as it will be shown it is nearly optimal for risk sensitive cost functional with risk factor sufficiently small. Part of the results presented at the talk is based on a joint contribution with dr Jan Palczewski.

Approximate formulas for zero-coupon bonds. **Gilberto Schleiniger** (University of Delaware, USA), Patrick Hagan (Brevan Howard Asset Management, UK), Fabricio Tourrucôo (Universidade Federal do Rio Grande do Sul, Brazil) IC/CT4350/081

Using perturbation methods we obtain approximate formulas for zero-coupon bonds. We present numerical simulations that partially validate the asymptotic approximation. Additionally, a calibration strategy is investigated in order to fit the model to given data on discount rates.

Stochastic rumours with an application of economics. **Selma Belen** (University of Cag, Turkey) IC/CT3082/082

In this paper, we adopt the model[1] to an investment problem. Our stochastic numerical results show that when the rumour about an investment is repeated the proportion of the population never investing approximates to 0.0049 as the population size tends to ∞.

This work is a joint work with C.E.M. Pearce.

Numerical methods for pricing european and american options under Levy processes. **Justin Wan** (University of Waterloo, Canada) IC/CT3697/025

In this talk, we present numerical methods for solving partial integro-differential equations arising from pricing European and American options when the underlying asset is driven by a CGMY process. In the infinite activity case, the kernel of the integral term will become singular at the origin. We propose an accurate finite difference method which captures the jump component near zero by a modified diffusion. The resulting discretization yields a linear system which is dense due to the integral term. Two iterative methods are discussed for solving the discrete system effectively. Convergence analysis of the iterative methods is presented. Finally, numerical results are given to demonstrate the effectiveness of the methods.

This is a joint work with Iris Wang and Peter Forsyth.

Substitutable-inventory system with partial back-logging. **Neelamegam Anbazhagan** (Thiagarajar College of Engineering, India) IC/CT745/082

This article presents a two commodity stochastic inventory system under continuous review. The maximum storage capacity for the i-th item is fixed as S_i $(i = 1, 2)$. It is assumed that demand for the i-th commodity is of unit size and demand time points form Poisson distribution with parameter λ_i, $i = 1, 2$. The reorder level is fixed as s_i for the i-th commodity $(i = 1, 2)$ and the ordering policy is to place an order for $Q_i (= S_i - s_i)$ items for the i-th commodity (i = 1, 2) when both the inventory levels are less than or equal to their respective reorder levels. The lead time is assumed to be exponential. The two commodities are assumed to be substitutable. That is, if the inventory level of one commodity reaches zero, then any demand for this commodity will be satisfied by the item of the other commodity. If no substitute is available, then this demand is backlogged up to a certain level N_i, $(i = 1, 2)$ for the i-th commodity. Whenever the inventory level reaches N_1 or N_2, both inventory levels are pull back to its maximum level S_1 and S_2 instantaneously by canceling the previous orders. For this model, the limiting probability distribution for the joint inventory levels is computed. Various operational characteristics and expression for long run total expected cost rate are derived.

A jump telegraph model for option pricing. **Nikita Ratanov** (Universidad del Rosario, Colombia) IC/CT217/008

A new class of financial market models is developed. These models are based on generalized telegraph processes: Markov random flows with alternating velocities and jumps occurring when the velocities are switching. While such markets may admit an arbitrage opportunity, the model under consideration is arbitrage-free and complete if directions of jumps in stock prices are in a certain correspondence with their velocity and interest rate behaviour. An analog of the Black-Scholes fundamental differential equation is derived, but, in contrast with the Black-Scholes model, this equation is hyperbolic. Explicit formulas for prices of European options are obtained using perfect and quantile hedging.

IC/PP4839/081: Double optimal stopping of a risk process.

Presenter: Krzysztof Szajowski (Wroclaw University of Technology, Poland)
Co-author: Anna Karpowicz (Warsaw University of Technology, Poland)

The following problem in risk theory is considered. An insurance company receives premiums and pays out claims which have occurred according to a renewal process and which have been recognized by them. The capital of the company is invested at interest rate $\alpha \in \Re^+$, the size of claims increase at rate $\beta \in \Re^+$ according to an inflation process. The immediate payment of claims decreases the company investment by rate α_1. At any moment the company may broaden or narrow down the offer, what entails the change of the parameters. This change concerns the rate of income, the intensity of renewal process and the distribution of claims. After the change the management wants to know the moment of the maximal value of the capital assets. The goal is to find two optimal stopping times: the best moment of change the parameters and the moment of maximal value of the capital assets.

The improvement to the known models is made by taking into account different scheme of claims payment and the possibility of rejection of the request by the insurance company. The proposed model takes into account different economical environments of insurance companies. It leads to essentially new risk process and the solution of optimal stopping problem is different.

IC/PP710/082: On the existence and uniqueness of a bounded mean-reverting process.

Presenter: Dharma Lesmono (Catholic University of Parahyangan, Indonesia)

We study the behaviour of a mean-reverting process described by the Stochastic Differential Equation (SDE):

$$\mathrm{d}S(t) = -\mu \frac{S(t)}{1 - S(t)^2}\,\mathrm{d}t + \sigma\,\mathrm{d}B(t)\,, \quad S(0) = S_0\,,$$

where $B(t)$ is one-dimensional Brownian motion, and μ and σ are positive constants. We prove that solution $S(t)$ remains within $(-1,1)$ whenever $|S_0| < 1$ and $\mu \geq \sigma^2$. The process behaves like the ubiquitous Ornstein–Uhlenbeck (OU) process when $S(t)$ is close to zero, but as $S(t)$ gets close to ± 1, the influence of the drift increases, thus driving the process away from the boundaries. Consequently, this SDE might be useful for modelling phenomena such as opinion polls, which have inherent maximum and minimum limits imposed.

The drift coefficient is not continuous near $S = \pm 1$. Nor does it satisfy either a Lipschitz or linear growth condition. Despite this, we will prove that there exists uniquely a solution to the SDE. We then extend this result to the case where the numerator of the drift coefficient is a polynomial in S.

Work done in collaboration with Prof. Phil Pollett (University of Queensland), Dr. Elliot Tonkes and Prof. Kevin Burrage (University of Queensland).

IC/PP4301/083: Estimations of the parameters of the smoothly-truncated Lévy distributions and their applications to EEG-sleep patterns.

Presenter: Alexandra Piryatinska (San Francisco State University, USA)

The class of Smoothly Truncated Lévy (STL_α) distributions (Koponen,1995) is an intermediate class of distributions between α-stable and normal distributions. The MM and Numerical MLE parametric estimation tools for these distributions are developed. The results are verified by simulations.

The above methods are applied to a study of the recordings of EEG sleep signals for fullterm and preterm neonates. The EEG data are not stationary. Our fist problem is to separate the time series into quasi-stationary increments. For the homogeneous increments the numerical MLE for smoothly truncated Lévy distribution is performed. The conclusion is that the STL model is appropriate for EEG-sleep patterns of fullterm babies.

IC/PP3494/085: On some new method of incorporating prior information into regression analysis and its performance in real-world applications: cross-validation analysis.

Presenter: Zbigniew Domański (Czestochowa University of Technology, Poland)
Co-author: Andrzej Grzybowski (Czestochowa University of Technology, Poland)

The presentation is devoted to the problem of incorporating prior information when estimating regression parameter. To incorporate the information together with its uncertainty into regression analysis we use estimators based upon the notion of a coefficient of uncertainty. In this presentation we focus on simulation analysis of these estimators. In our studies we use real world data, so we adopt the cross-validation technique. We compare the performance of predictors based on the considered estimators with the performance of the predictors based on the ignoring prior information least-squares estimator. The data used in presented applications are connected with steel plate properties modelling (important for steel works production management) as well as with some economic models (e.g. car or real estate market)

IC/PP3446/085: Incorporating prior information in regression estimation: on a coefficient of uncertainty based on the condition number of the matrix of observations.

Presenter: Andrzej Grzybowski (Czestochowa University of Technology, Poland)

The paper is devoted to the problem of incorporating prior information into regression model estimation. We assume the prior information about regression parameter is derived from regression analysis applied (perhaps by someone else) to some phenomenon described by the same regression equation. However, we cannot be sure that the two phenomena are described by exactly the same regression equations and we do not know how reliable the previous data and results are - the prior information is uncertain.On the base of computer simulation we construct a coefficient which allows incorporating the prior information along with its uncertainty. The coefficient is based upon the index number of the matrix of observations of the explanatory variables as well as its dimensions. Performance of estimators based upon the coefficient of uncertainty is examined through computer simulations. In the simulations the performance of the proposed estimators is compared with performance of the usual ordinary least squares estimator

IC/PP1543/015: Bootstrap estimation of the distribution of Kullback–Leibler distance in the mixed case.

Presenter: Virtudes Alba-Fernández (Universidad de Jaén, Spain)
Co-author: Dolores Jiménez-Gamero (Universidad de Sevilla, Spain)
Co-author: Joaquín Muñoz-García (Universidad de Sevilla, Spain)

In many statistical techniques, computation of a distance between two populations is often useful. For example, to test the equality of two populations one can consider some sample version of a distance between the theoretical populations as a test statistic and reject the null hypothesis for large values of the estimated distance. Let X_i, $i = 1, 2$, be two random vectors with densities f_i with respect to a σ-finite measure λ, respectively, and let $d(f_1, f_2)$ denote the symmetric version of the Kullback-Leibler distance between them.

We will assume that that each random vector X_i, $i = 1, 2$, has q continuous components and d discrete components and that it has a CG distribution, that is, the set of discrete variables define a multinomial vector with s possible states each having probability p_i, $\sum_{i=1}^{s} p_i = 1$, and conditionally on the state i, the distribution of the q continuous variables is $N(\mu_i, \Sigma_i)$.

Replacing p_i, μ_i and Σ_i, $i = 1, 2$ by its maximum likelihood estimators of we obtain the sample version of $d = d(f_1, f_2)$, say $\hat{d}$, that can be used as test statistic to test the homogeneity of both distributions. With this aim, we need to known or at least to approximate the null distribution of $\hat{d}$. As an approximation to it Bar-Hen and Daudin (J. Multivariate Anal., 53, 332–342 (1995)) have derived the asymptotic null distribution. Here we study another way to approximate it: the bootstrap. We show that the bootstrap estimates consistently the null distribution of $\hat{d}$. We also study by simulation the finite sample performance of the bootstrap distribution and compare it with the asymptotic approximation.

09: Solid Mechanics, Minisymposia

IC/MP200/009: **Configurational mechanics.**

Organiser: Ralf Müller (TU Darmstadt, Germany)
Co-organiser: Paul Steinmann (TU Kaiserslautern, Germany)
Co-organiser: Gérard Maugin (Université Pierre et Marie Curie, France)

Since the seminal works of Eshelby (1951, 1970) the general notion of configurational forces has been successfully applied in many defect situations in continuous media. The ideas of Eshelby were later picked up by many scientists to establish a theory of configurational forces, also addressed as theory of material forces. Based on different approaches the theory proves to be very valuable for the analysis of all kinds of defect situations, including point, line and surface defects or distributed inhomogeneities. The most prominent and most developed application is of course the use the configurational forces in fracture mechanics. As configurational forces are related to material inhomogeneities they have successfully been used in many material science and engineering problems with phase transitions and inelastic deformations. Also the modeling of materials with micro-structure evolution is one of the fields, in which configurational forces can provide a better understanding of processes going on within the material.

Besides these mechanically, physically, and chemically motivated situations, configurational forces are now used in computational mechanics. Especially, the combination of configurational forces and finite element methods had an impact in computational mechanics. New methods based on configurational forces are developed in numerical fracture mechanics, structural optimization and adaptivity. These methods include, for example, the so-called r- and h-adaptive methods for mesh optimization and refinement. These new developments in computational mechanics are a lively activity, which help to extend the concepts to inelastic and dynamic problems.

Reciprocity in material space. **Reinhold Kienzler** (Universität Bremen, Germany), George Herrmann (Stanford University, Tonga) IC/MT1106/009

Reciprocity relations play a prominent role in various areas of classical physics and mathematical modelling and are most useful in the solution of numerous problems. In the theory of elasticity of solids, relevant reciprocity theorems have been established during the course of the second half of the 19^{th} century by Maxwell, Helmholtz, Lamb, Betti and Rayleigh.

To recall, as an example, Maxwell's reciprocity theorem, as applied to the elastostatics of a beam, let us consider two loading states, the force F_1 applied at the position x_1 and the force F_2 applied at the position x_2. The reciprocity theorem states that the work of the force F_1 exerted at the displacement at x_1 resulting from the force F_2 is equal to the work of the force F_2 exerted at the displacement at x_2 resulting from the force F_1.

The elements of what might be called *Mechanics in Material Space*, as a counterpart of the conventional or usual *Mechanics in Physical Space* have put together by the authors in a recent monograph [1]. Material forces are interpreted as the gradient of the total energy of a body with respect to the position of a defect within the material. A material translation is understood as a change of the configuration of that body due to change in location of a defect relatively to the material in which the defect is placed.

In order to establish reciprocity in Material Space, a body is considered which contains two defects at positions x_1 and x_2, respectively. Under external load, material forces B_{10} and B_{20} can be calculated. Due to a material translation of the defect 1, say δ_1, both material forces change to B_{11} and B_{21}, whereas due to a material translation of the defect 2, say δ_2, the material forces change to B_{12} and B_{22}. By changing the order of succession of the material translation (first δ_1, second δ_2, and vice versa), a reciprocity theorem follows. Details of the derivations are given in the talk. The application of the theorem is illustrated by several examples. Especially defect-interaction problems are discussed.

The balance of material momentum at a shock wave propagating in a thermo-elastic material. **Manfred Braun** (Universität Duisburg-Essen, Germany) IC/MT3122/009

Any global balance law can be reduced to its local or divergence form provided the variables involved are differentiable. At a surface of discontinuity, balances are expressed by the corresponding jump conditions. By comparing the continuous and discontinuous versions of the balance laws, one can find a simple rule, how a jump condition is related to the corresponding divergence form of the underlying balance law.

The balance of material momentum can be obtained directly from the balance of physical momentum by projecting it onto the material space. This derivation, however, is valid for the continuous case only. At a surface of discontinuity, the balance of pseudomomentum is represented by a corresponding jump condition, which can be derived from the jump condition of physical momentum in a similar way as in the continuous case. If the material is assumed purely elastic, i. e., without any dependence on thermodynamic variables, the jump condition of material momentum deviates from the form that is expected on the basis of its continuous counterpart. In general, an additional source term is involved which is of third order in the strength of the shock.

The discrepancy is resolved as soon as thermodynamics is taken into account. Stress and (internal or free) energy densities now depend not only on strain but also on a thermodynamic variable (entropy or temperature), and the balance of physical momentum has to be supplemented by the energy balance. On account of these two physical balance laws, the balance of material momentum assumes the expected form, even across a singular surface. The analysis indicates that thermoelastic behavior should be taken into account to describe shock waves in elastic materials properly.

On variational sensitivity analysis and changes in the material configuration. **Daniel Materna** (Universität Dortmund, Germany), Franz-Joseph Barthold (Universität Dortmund, Germany) IC/MT1970/009

This contribution is concerned with the application of variational design sensitivity analysis in the context of structural optimization and configurational mechanics. Variational design sensitivity analysis is a branch of structural optimization, e.g. shape or topology optimization. In these disciplines we consider variations of the material configuration and we are interested in the change of the state variables and the objective functional due to these variations. These sensitivities are required in order to solve the corresponding Lagrangian equation within standard optimization algorithms.

In many engineering applications, the energy functional of the problem is used as the objective functional of the optimization problem. The first sensitivity of the energy functional with respect to changes in the design leads to the well-known weak form of the material or configurational force equilibrium, which is directly related to the energy-release rate. The second sensitivity of the energy functional provide information about

the sensitivity of the energy-release rate and yields a tangent operator in order to solve the material motion problem. Furthermore, we investigate the so-called pseudo load operator, which is derived from the sensitivity of the physical motion problem. The sensitivity of the physical as well as the sensitivity of the material motion problem depend on the structure of the pseudo load operator. Both problems are coupled by this operator and some important properties will be studied in this context. Finally, we will summarize our recent process in the theoretical as well as computational treatment by means of selected examples.

Configurational-force-based structural updates and adaptive remeshing strategies. **Dominik Zimmermann** (Universität Stuttgart, Germany), Christian Miehe (Universität Stuttgart, Germany) IC/MT3844/009

We investigate the application of configurational forces in h-adaptive strategies for elastic fracture mechanics and inelasticity. In a first step, a consistent dual physical and material thermodynamic framework of finite inelasticity is discussed. Starting from a global Clausius–Planck inequality dual equilibrium conditions are derived by a Coleman type exploitation method. From the remaining reduced global dissipation inequality the evolution equations for the internal variables are derived by the principle of maximum dissipation. Adopting these considerations to fracture mechanics, crack loading conditions as well as a normality rule for the crack propagation are obtained. In the discrete setting, the crack propagation is governed by a configurational force driven update of the underlying geometry model. The material balance equation is used to set up a h-adaptive refinement indicator. For a homogeneous body, this balance law corresponds to vanishing discrete configurational nodal forces. However, due to insufficient discretization, configurational forces occur at the interior nodes of the mesh. Their norm is used as an isotropic refinement indicator. Adopting the clear energetic interpretation of configurational forces in elasticity, where they may be related to the energetic misfit of the discretization, to problems of finite inelasticity, a relative global criterion is defined which is used for the decision on mesh refinement. Following the same reasoning, a criterion on the element level is defined which governs the local refinement procedure. The numerical treatment is carried out by coupling efficient software tools for the adaptive mesh generation, the finite element assembley and solution process, and the postprocessing step including the evaluation of the discrete configurational nodal forces. The capability of the proposed procedure is demonstrated by means of representative numerical examples.

IC/MP200/009: Configurational mechanics. #2

Multiscale damage simulation. **Mario Timmel** (Universität Leipzig, Germany), Michael Kaliske (TU Dresden, Germany), Stefan Kolling (DaimlerChrysler, Germany), Ralf Müller (TU Darmstadt, Germany) IC/MT1945/009

Numerous materials often show a softening behaviour under dynamic loading. The decrease of stress, hereby, is caused by the evolution in the microscale in terms of areas where the local stiffness is reduced, e.g. due to micro-void growth. For a numerical treatment of this material behaviour, phenomenological damage approaches are used in daily engineering practice. For a better understanding of the micromechanical process of such phenomenological models, multiscale methods are becoming increasingly important. The physical quantities that are responsible for the microstructural evolution associated with the damage process are transferred to the numerical model. In this context, we use the method of configurational forces to describe the geometrical changes of damaged areas. Hereby, we present the general case of hyperelastic materials at finite strains. For the restriction of small strains, the microstructural evolution will be shown for elastoplastic materials with and without rate effects. The numerical twoscale procedure based on an explicit finite element code is presented in detail where an addition boundary value problem representing the microscale is solved in every Gaussian point. The methodology is applied to some illustrative examples.

Damage and size effects in elastic materials: a homogenization approach. **Cristian Dascalu** (Université Grenoble I, France) IC/MT2429/009

A damage model is constructed using the configurational force balance and an explict description of micro-crack evolution. We use periodic homogenization based on asymptotic developments. We show that the balance of configurational forces is able to capture size effects, which are incorporated in the resulting macroscopic damage law.

A numerical modelling based on different elementary behaviors, obtained through homogenization, allow us to take into account complex microstructural aspects like multiple microcrack orientations, unilateral contact, friction etc. We illustrate the ability of the model to reproduce known behaviors, eg. localization of damage.

Fracture mechanical investigations of rate-dependent inelastic materials at large strains. **Bastian Näser** (Universität Leipzig, Germany), Hüsnü Dal (TU Dresden, Germany), Michael Kaliske (TU Dresden, Germany) IC/MT2284/009

The material force approach is an efficient, elegant and accepted means to compute the J-integral as a fracture mechanical parameter for elastic and inelastic materials. With the formulation of a multiplicative split of the deformation gradient at hand, rate-dependent (visco-elastic) materials based on the Bergström-Boyce-Model can be investigated. For these investigations, the so-call material body forces have to be computed to separate the driving force acting on the inelastic zone around the crack tip from the driving force acting on the crack tip itself , representing the crack driving force or the J-integral, respectively. For that purpose, the complete balance for the material motion problem for rate-dependent, inelastic materials has to be known and the balance has to be fulfilled at every nodal point in a finite element discretization.

This contribution presents the formulation of the material balance and the corresponding material body forces for rate-dependent inelasticity, shows examples to prove the correctness of the formulation and implementations and gives some applications in fracture mechanics.

IC/MP327/090: Dynamics of defects in materials.

Organiser: Isaac Chenchiah (University of Bristol, UK)
Co-organiser: Thomas Blesgen (California Institute of Technology, USA)

Recent years have seen much interest in the understanding of the dynamics of defects in materials, in both the applied mathematics and engineering communities. Much progress has been made, for example, in the understanding of discrete models for defects. Further, while substantial open problems remain, sufficient progress has been made to profitably introduce the engineering community to mathematical developments. Conversely exposure to the challenges faced by the engineering community, and to the larger context in which defect motion occurs would benefit the applied mathematics community.

This minisymposium, which is addressed to both applied mathematicians and engineers, has three aims: Firstly, to facilitate interaction between researchers working on various mathematical aspects of defect motion in materials. Secondly, to review mathematical developments for researchers in the engineering community, and vice-versa. Thirdly, to stimulate interaction between applied mathematicians and engineers.

To accomplish the achievement of these goals, the minisymposium will include two review talks: one reviewing mathematical developments for a non-mathematical audience, and the other reviewing developments in the engineering community for a mathematical audience. Specific issues to be addressed in the other talks are: discrete models, passage from discrete to continuum models, multiscale aspects, and defect motion as contributing to other material phenomena.

Atomistic and continuum models of defects in solids. **Weinan E** (Princeton University, USA) IC/MT4843/090

I will give an overview of the atomistic and continuum models of defects in solids. Specifically I will discuss the dynamics of impurity diffusion, dislocation and twin boundary motion as examples of zero, one and two dimensional defects. I will discuss the atomistic mechanisms as well as continuum models for these examples.

A model of distributed faulting in confined brittle materials. **Anna Pandolfi** (Politecnico di Milano, Italy), Sergio Conti (Universität Duisburg-Essen, Germany), Michael Ortiz (California Institute of Technology, USA) IC/MT4833/090

We present a model of distributed damage in brittle materials undergoing triaxial compression. We aim to compute the effective or macroscopic behavior of the material from its elastic and fracture properties; and to predict the microstructures underlying the microscopic behavior. Additionally, we present the numerical implementation of the damage model within a concurrent multiscale framework, and the validation of the model against the experimental data of pertaining to compressive damage in confined ceramics.

Processes of distributed damage in brittle materials have been modelled by a variety of means. Local models of distributed damage have been in some cases misapplied to processes of fracture in brittle solids under tension, where fracture mechanics is expected to govern the behavior of the solid. One of the aims of the present paper is to elucidate the conditions under which damage occurs in a distributed fashion, and therefore can be described by a damage model. We show that distributed damage, as opposed to fracture, is a compressive phenomenon and only occurs when sufficient confinement is present.

The approach followed in the present paper is based on methods of the calculus of variations. We suppose that the displacement field jumps discontinuously across a singular set of co-dimension 1, and that the energy is composed of two terms: the elastic strain energy obtained by volume integration outside the singular set; and the cohesive fracture energy obtained by surface integration over the singular set. However, in contrast to recent work on free-discontinuity problems in fracture mechanics, that has emphasized tensile conditions leading to the formation of isolated dominant cracks, here we envision conditions of triaxial compression resulting in a distributed singular set. We specifically consider singular sets that are composed of recursive or nested faults, and show that these microstructures or damage patterns suffice to fully relax the energy.

A recursive fault pattern may be constructed by introducing into the solid a family of parallel planar cohesive cracks, or faults, and subsequently applying that construction recursively to the intervening matrix between the faults. The state of stress within each level of faulting is uniform, and therefore in equilibrium, although the different levels of faulting are only approximately compatible. Recursive faulting can be implemented simply by means of a recursive call, and the entire microstructure needs not be considered at any time during the construction. The approximate compatibility between levels of faulting has the effect of building additional misfit elastic energy into the microstructure. We estimate this misfit elastic energy simply by modelling the approximate interfaces as rows of dislocation dipoles. This simple estimate permits the calculation of the separation between the faults, and provides a natural termination criterion for the recursive faulting algorithm.

Homogeneous nucleation of dislocations. **Ana Carpio** (Universidad Complutense de Madrid, Spain) IC/MT4853/090

We present a mathematical theory of nucleation of dislocations is crystals. The dynamics of crystal atoms is described by a discrete elasticity model with a periodic dependence on discrete strain which changes with the type of bond. In a perfect 2D cubic lattice, dislocations are nucleated when a large enough shear stress is applied and then move towards the boundary. The resulting pattern depends on the magnitude of the load, the size of the crystal and the periodic nonlinearity. Nucleation corresponds to a bifurcation in the branch of solutions describing sheared lattices as the shear grows. We are able to predict the critical stress for nucleation and the location of nucleation sites.

Relaxation and microstructure formation in single-crystal plasticity. **Sergio Conti** (Universität Duisburg-Essen, Germany) IC/MT4845/090

This contribution deals with single-crystal plasticity with large latent hardening, which signifies that deformations which are single slip at each material point are favored. The resulting nonconvexity of the incremental variational problem induces the formation of fine-scale structures. In a geometrically nonlinear framework, and with rigid elasticity, an explicit relaxation is obtained for the case that a single slip system is active (in the two directions), both without self-hardening and with linear self-hardening. Our construction shows that laminates are formed, and that plastic deformation is present only in one of the two phases. We then extend the result to the non-rigid case, still with only one active slip system. This is done by combining a partial analytical relaxation with a numerical relaxation algorithm. The latter contains both a local optimization of the laminate and a check for optimality, based on the construction of a polyconvex lower bound. As a second example, the full set of fcc slip systems is considered, within linearized kinematics. We show that, by developing microstructures in the form of sequential laminates of finite depth, crystals can beat the latent hardening. The relaxed constitutive behavior is indistinguishable from multislip ideal plasticity. We find, however, that relaxation requires the introduction of slip lines in the microstructure, i.e., lines of concentrated slip and discontinuous displacement.

IC/MP3479/092: Higher-order asymptotic homogenisation and wave scattering in periodic composite structures.

Organiser: Igor Andrianov (RWTH Aachen, Germany)

Many studies in the theory of composite materials are based on the exploitation of the classical continuum model assuming that the original heterogeneous medium can be substituted by a homogeneous one with certain homogenized (so called effective) mechanical properties. However, this idealized assumption can not be applicable to a number of practical problems. In real composites the micro structural scale effects may result in specific non-local phenomena which can not be predicted in the frame of the homogenized medium theory.

Scale effects can be systematically analysed by means of the higher-order asymptotic homogenization method (AHM). In static problems the heterogeneity of the medium results in the induction of an infinite series of displacement fields with successively lower amplitudes. On macro level, instead of homogenized equilibrium equations of continuum mechanics we obtain new equilibrium equations that involve higher order spatial derivatives and thus represent the influence of the micro structural heterogeneity on the macroscopic material's behaviour.

In dynamic problems the physical role of the scale effects is even more significant. When the wavelength of a travelling signal becomes comparable to the characteristic size of heterogeneities, successive reflections and refractions of the waves at the components' interfaces lead to the formation of a complicated sequence of so called pass and stop frequency bands. In this case the composite plays a role of a discrete frequency filter. Application of the AHM provides a long-wave approach valid in the low frequency range. Solution for the high frequencies can be obtained on the basis of the Floquet–Bloch theorem by one of the following approaches: the plane-wave expansions method, the Rayleigh multipole-expansions method, and the Korringa–Kohn–Rostoker method (also known as the multiple scattering method).

The aim of the minisymposium is the presentation and the comparative analysis of the modern approaches for the higher-order simulation of periodic composite structures taking into account the scale effects and the wave scattering phenomena.

Study of wave dispersion in periodic composites by higher-order asymptotic homogenization method. **Vladyslav Danishevskyy** (Prydniprovska State Academy, Ukraine), Igor Andrianov (RWTH Aachen, Germany), Vladimir Bolshakov (Prydniprovska State Academy, Ukraine), Dieter Weichert (RWTH Aachen, Germany) IC/MT3882/092

In the present work an application of the higher-order asymptotic homogenization method (AHM) to the study of wave dispersion in periodic composite structures is considered. It should be noted that the most significant and practically important phenomena caused by the heterogeneity of the composite media arise in dynamic problems. When the wavelength of a travelling signal becomes comparable to the size of heterogeneities, successive reflections and refractions of the waves at the components' interfaces lead to the formation of a complicated sequence of so called pass and stop frequency bands. In this case the composite plays a role of a discrete frequency filter.

As illustrative examples we study propagation of harmonic elastic waves in a layered composite (one-dimensional problem allowing the exact analytical solution) and in a fibre-reinforced composite with a square lattice of cylindrical inclusions (two-dimensional problem). The asymptotic homogenization schemes are developed and the higher-order macroscopic wave equations are derived. Analysis of the obtained solutions shows that the AHM provides a long-wave approach valid in the low frequency range. Solutions for the high frequencies are obtained on the basis of the Floquet-Bloch theorem by expanding spatially varying material properties in Fourier series and representing unknown displacement fields by infinite plane-wave (PW) expansions. However, this approach may run into convergence problems with the increase in contrast between the components properties. Eventually, we can conclude that the higher-order AHM and the PW expansions method can be treated as complementary to each other. The dispersion curves relating the wave numbers and frequencies are obtained; the pass and stop frequency bands are identified; the attenuation factors within the stop bands are evaluated.

Long-wave scattering by a periodic distribution of oscillators on the free surface. **Claude Boutin** (ENTPE, France) IC/MT3922/092

This article is devoted to wave propagation in presence of a periodic distribution of oscillators (3D spring-damped masses) on the surface of an elastic medium. The case of an elastic half-space loaded by quasi-periodic surface forces is studied first. The equivalent boundary conditions at the macro-scale are derived at the first and second order, by assuming the existence of a boundary layer and using a two-dimensional homogenisation method. When the force distribution results from attached oscillators, it is shown that boundary conditions can be expressed in terms of equivalent surface impedance at the first order, with local and non local correctors at the second order. These results are used to study wave refraction by an oscillator layer. The main phenomena - atypical redistribution of mode and mode conversion, frequency range of efficiency, characteristic time of response - are identified. The first correctors are determined analytically for plane waves of oblique incidence. Finally the validity range of the modelling is discussed.

Wave propagation and diffraction in discrete structures: effect of anisotropy and internal resonance. **Claude Boutin** (ENTPE, France), Celine Chesnais (Ecole Nationale des Travaux Publics de l'Etat - CN, France), Hans Stephane (ecole Nationale des Travaux Publics de l'Etat - CN, France) IC/MT4072/092

This paper is devoted to the study of wave propagation within discrete periodic bi-dimensional structures. The problem is tackled by considering a class of structures made of repeated un-braced frames. The behaviour of these frame structures is determined by the distribution of shear force and inner bending in the elements according to their mechanical and geometrical characteristics. Moreover, since resisting elements are only present in two directions, the global system is highly anisotropic.

Assuming the frame size is small compared to the wavelength, the macroscopic equivalent descriptions are obtained by the homogenization method of periodic discrete media. Depending on the considered frame structure and on the order of magnitude of the frequency (relatively to the scale ratio) several families of waves are proven to be possible. Increasing the order of the frequency one obtains:

- pure shear waves propagating in the direction of the frame, while in other directions the regime remains quasi-static;
- modes of shear-compression waves. At this level of frequency the elements reach their resonance (in bending). This internal resonance leads to a frequency depending apparent mass of the system that in turn, induces a dispersion of waves. Note that the quasi-Shear mode propagates except in the directions of the frame (in these directions the diffraction regime is already reached), and the quasi-compression mode reduces to pure compression waves in the directions of the frame.
- full-diffraction range where no propagation modes can exist.

These theoretical results show that the high anisotropy induces very separated diffraction frequencies according to the considered modes. Therefore propagation and diffraction may occur conjointly at the same frequency. To conclude analogies with micromorphic media are discussed.

Continuous models of discrete media valid for the high-frequency domain. **Igor Andrianov** (RWTH Aachen, Germany) IC/MT4151/092

Microstructural effects play a significant role in the mechanical behaviour of heterogeneous materials and are essential in problems of damage mechanics, molecular dynamics, theory of plasticity, mechanics of composites, nanomechanics.

These effects can be taken into account using either discrete or continuous models. Let us focus on the continuum description of the dynamic behaviour of microstructural materials. Each component can be modelled separately by means of the classical continuum, and then the microstructure is considered as a heterogeneous classical continuum. On the other hand, a homogeneous continuum can be used and the influence of the microstructure can be taken into account by averaging. Here three strategies exist: the phenomenological approach (additional terms are added to the energy functional or to the constitutive relation; the structure and character of these terms are postulated), the statistical approach (starting from a heterogeneous classical continuum average values of the state variables are computed to produce enhanced field equations), and the homogenization approach (based on G-limit technique). The applicability of all the above mentioned models in dynamics is restricted to limited ranges of frequencies. At high frequencies, these models either become unstable or presume an infinite speed of the energy propagation. From a physical standpoint, the inapplicability of homogeneous continuum models at high frequencies is fully justified, since the heterogeneity and anisotropy of microstructural materials cannot be ignored as the wavelength size approaches the span of the microstructural irregularity.

We propose a new approach to obtain explicit relations between micrtostructural properties and microstructural parameters. It is based on the asymptotic construction of two limiting cases and further using of two-point Padé approximants.

IC/MP697/092: Geometric and stochastic aspects of the mechanics of complex bodies.

Organiser: Paolo Maria Mariano (Università degli Studi di Firenze, Italy)
Co-organiser: Thomas Pence (Michigan State University, USA)
Co-organiser: Eric Vanden-Eijnden (Courant Institute, NYU, USA)

Stringent industrial requirements of sophisticated performances and of circumstantial control for micro-devices or nanotechnology manufactures (and other types of machinery at multiple scales) can be often satisfied only by resort to or allowance for complex materials. The adjective *complex* beckons to the fact that the substructure influences the gross mechanical behaviour in a prominent way by means of interactions due to substructural changes, interactions that have to be represented directly generating non-trivial geometrical questions. Moreover, geometry plays a crucial role above all to underline the invariant (or better covariant) structures of the models one manages. There is a crucial interplay between geometry and analysis when one looks for the possibility of finding solutions or at least relevant existence theorem, as it occurs in evaluating the existence of ground states of elastic complex bodies. The description of the mechanical behaviour of complex bodies proposes a wide class of challenging problems of mathematical, physical and computational nature from macroscopic-to-nano-world. However, substructures are not necessarily micro or nano; for example in turbulence of polymeric fluids the formation at mesoscopic level of coherent structures due to the interplay between macroscopic motion and microscopic self-organization of polymeric chains influences drastically the whole scenario of the macroscopic motion. This is just an example, of course. Stochastic effects occur in prominent cases as the segregation of phases, turbulence of complex fluids and the interaction between phonon and phason modes in quasicrystals. These effects may also be rare events of crisis. Finally, computations require non standard methods involving approximations over manifolds. In working about complex bodies one becomes aware that often points of departure that seem of disparate nature manifest at the end unexpected connections and common foundations.

The basic aim of the proposed minisymposium is to show different aspects of the mechanics of complex bodies from theory to computations and the subtle connections between them, paying above all attentions on geometrical and stochastic questions arising from physical modelling and on the related computational problems.

A quest for an extended *continuum mechanics.* **Gianfranco Capriz** (Università di Pisa, Italy) IC/MT3190/092

Earlier reflections on balance equations possibly appropriate for hyperfluids or pseudofluids (reflections broached originally so as to dispose of lack of strict objectivity in standard thermal quantities) are instanced again with a different slant. It is alleged that partially chaotic motions can be efficiently branded by assigning pertinent averages, moments and variances and these gauges can be all (not only the first two) considered mechanical; hence the qualifier 'extended'. A few immediate consequences of the approach are derived, open problems are listed, connections or dissensions with widely acknowledged notions are discussed.

Shearing deformations for a class of elastic materials with an internal balance based on a decomposition of the deformation gradient . **Thomas Pence** (Michigan State University, USA), Hasan Demirkoparan (Carnegie Mellon - Qatar) IC/MT2440/092

In order to model certain substructural reconfigurations in solids we consider a standard multiplicative decomposition of the deformation gradient and consider constitutive laws based on separate energy minimization of the decomposition factors. It is found that even very simple constitutive laws formulated on this basis give rise to interesting possibilities for localized deformation. This is demonstrated in boundary value problems involving shearing wherein certain applied traction thresholds, or applied shear thresholds, give rise to energy minimizers involving discontinuity of deformation in an appropriate limiting sense.

Small-scale anisotropy in shear turbulence. **Massimo Casciola** (Università degli Studi di Roma "La Sapienza", Italy) IC/MT2461/092

According to Kolmogorov, isotropy is recovered in the large Reynolds number limit as the scale is reduced and, in the so-called inertial range, universal features (namely the scaling exponents of structure functions) emerge clearly. However this picture is violated in a number of cases, typically in the high shear region of wall bounded flows. The common opinion ascribes this effect to the contamination of the inertial range by the larger anisotropic scales; i.e., the residual anisotropy is

assumed as a weak perturbation of an otherwise isotropic dynamics. This kind of reasoning fails when the anisotropic effects are strong as in the production range of shear dominated flows. This regime is analyzed here by means of both numerical and experimental data for a homogeneous shear flow. A well defined scaling behavior is found to exist, with exponents which differ substantially from those of classical isotropic turbulence. A systematic use of the $\mathrm{SO}(3)$ decomposition on the correlation tensors of velocity fluctuations enables to extract the different anisotropic contributions. They vanish at small scale at a relatively fast rate under weak shear. Under strong shear instead they keep a significant amplitude up to viscous scales, thus leaving a signature on the gradients.

Finally, the general validity of these results is discussed in the context of applications, where more appropriate closure models would be advisable. In fact, as we will show, commonly we find conditions under which statistical isotropy is never recovered and where the anisotropy induced by large scale shear contaminates the entire range of scales up to velocity gradients.

Asymptotic analysis and relaxation of Mumford–Shah type energies with obstacles. **Matteo Focardi** (Università di Firenze, Italy) IC/MT2512/092

Homogenization of particle-reinforced composites and porous bodies may involve minimum problems for Mumford–Shah type functionals with obstacle conditions. For bodies with a periodic distribution of holes, one may be interested in analizing the behaviour of the (say) elastic energy as the diameter of the holes tends to 0. By selecting the Dirichlet energy as a prototype, one analizes the asymptotics as ε tends to 0 of mimimum problems of the type

$$\inf\left\{\int_\Omega |\nabla u(x)|^p \mathrm{d}x + \mathcal{H}^{n-1}(S_u) + \text{ lower order terms} : u \in SBV(\Omega),\ u = 0 \text{ on } \mathbf{B}_\varepsilon \text{ and } \Omega,\right\}$$

where $\Omega \subset \mathbb{R}^n$ is a given regular bounded open set, ∇u and S_u are, respectively, the (approximate) gradient and the set of (approximate) discontinuities of u, and $\mathbf{B}_\varepsilon = \Omega \cap \cup_{\underline{i}\in\mathbb{Z}^n} B_{r_\varepsilon}(\underline{i}\varepsilon)$, with $B_{r_\varepsilon}(\underline{i}\varepsilon)$ the ball centered in $\underline{i}\varepsilon$ of radius $r_\varepsilon > 0$.

The restriction to the Sobolev space $W^{1,p}$, $p > 1$, is classical and has been analyzed in many works after the pioneering results by Marchenko and Khruslov [5], Rauch and Taylor[6,7] and Cioranescu and Murat[2].

The limit energy to be minimized contains an extra term which is a finite penalization keeping track of the local capacity density of the homogenizing obstacles (with the appropriate notion of capacity related to the Dirichlet type energy under consideration). In order to deal with this *relaxation phenomenon*, De Giorgi, Dal Maso and Longo[4] proposed an approach via Γ-convergence arguments for the associated Dirichlet energies[1,3].

Along this line, and taking into account the general case of unilateral constraints, we consider the functionals

$$F_\varepsilon(u) = \int_\Omega |\nabla u|^p \mathrm{d}x + \mathcal{H}^{n-1}(S_u) \quad u \in SBV(\Omega),\ u = 0\ \mathcal{L}^n \text{ a.e. on } \mathbf{B}_\varepsilon,$$

$+\infty$ otherwise in $L^1(\Omega)$, and show that (F_ε) Γ-converges in the L^1 topology to

$$F(u) = \int_\Omega |\nabla u|^p \mathrm{d}x + \mathcal{H}^{n-1}(S_u) + n\omega_n \beta^{n-1} \mathcal{L}^n(\{x \in \Omega : u(x) \neq 0\}),$$

where the coefficient β is finite and different from 0 if and only if $r_\varepsilon \sim \varepsilon^{\frac{n}{n-1}}$.

The term $n\omega_n$ is a capacity related to the *functional capacity of degree 1* of the reference hole $B_1(\underline{0})$. Here, we prove the Γ-convergence result for a generic reference perforation set E by replacing in the limit energy $n\omega_n$ with the 1-capacity of a suitable $\mathcal{L}^n$ representant of E. Moreover, we give an equivalent formulation of the obstacle problem for reference perforations with Lebesgue measure zero[8]. Eventually, we characterize the lower semicontinuous envelope of Mumford–Shah type energies with pure obstacles and show that it can be written by means of an $(n-1)$-dimensional variational measure introduced by De Giorgi in the study of minimal surfaces with obstacles [9].

Geometric models of internal structure and their group analysis. **Jan Slawianowski** (Polish Academy of Sciences, Poland) IC/MT3883/092

Suggested is a class of geometric models of bodies which are complex on the micro- and nano-level. Degrees of freedom of the internal structure of material elements are modelled with the use of homogeneous spaces of some transformation groups suggested by the very geometry of the physical space, like the real affine or unitary group and their subgroups. On the basis of the powerful methods based on group theory performed is a qualitative analysis and also analytical computations concerning the micro- and nano-dynamics. Quantization aspects are discussed because this realm of phenomena is characterized by the convolution and overlaping of the classical and quantum levels of description.

Boundary roughness effects in nematic liquid crystals. **Paolo Biscari** (Politecnico di Milano, Italy) IC/MT3617/092

Nematic liquid crystals possess three different phases: isotropic, uniaxial, and biaxial. The ground state of most nematics is either isotropic or uniaxial, depending on the external temperature. Nevertheless, biaxial domains have been frequently identified, especially close to curved surfaces. In the first part of the talk we show how the surface curvature tensor may be a source of biaxiality[1]. We then show how the boundary conditions weaken if the boundary roughness increases, and relate the microscopic roughness parameters to an effective anchoring potential, that replaces the (strong) boundary conditions[2].

Fluid dynamics of an open quantum system in the high-field regime. **Chiara Manzini** (Università degli Studi di Firenze, Italy), Giovanni Frosali (Università degli Studi di Firenze, Italy) IC/MT3705/092

Electronic devices operating in high-field regimes have become subject of interest for semiconductor modelists. Simulations of these devices were based on fluiddynamical models with parameters adapted to experimental values. More recently, novel models with field-dependent parameters have been proposed. The derivation of *quantum* macroscopic models from kinetic ones as in gasdynamic theory is delicate both from the analytical and the physical point of view. The conservative dynamics of the isolated quantum system has to be broken, by taking into account dissipative interactions with the environment; however, when considering the weak coupling of the system with the environment, a Markovian dynamics can still be adopted. A discussion of physically-consistent quantum kinetic models shall be proposed. Then, we shall consider the high-field Wigner-BGK equation and derive quantum drift-diffusion and quantum hydrodynamic models, containing *explicit* field-dependent terms.

Einstein relation on fractal objects. **Uta Renata Freiberg** (Australian National University) IC/MT4055/092

Many physical phenomena proceed in or on irregular objects which are often modeled by fractal sets. Using the model case of the Sierpinski gasket, the notions of Hausdorff, spectral and walk dimension are introduced. These "characteristic" numbers of the fractal are the "ingredients" of the Einstein relation, expressing the interaction of geometric, analytic and stochastic aspects of a set.

em Keywords*: fractals, self-similarity, Hausdorff dimension, Dirichlet form, Laplacian, spectral dimension, (strong) Markovian process, walk dimension, Einstein relation*

IC/MP56/092: Modeling, analysis and simulation of crystal defects: dislocation and surface step dynamics across the scales.

Organiser: Yang Xiang (Hong Kong University of Science and Technology)
Co-organiser: Dionisios Margetis (Univ. Maryland at College Park, USA)

Crystalline materials are used extensively in the design and fabrication of novel devices. The modeling of such materials, especially their defects, is an area of active research with numerous analytical and computational challenges. This minisymposium focuses on recent advances in the modeling, analysis and simulation of line defects inside crystals (dislocations) and on crystal surfaces (steps). These defects are of atomic size, but they influence the properties of crystals and the corresponding devices at mesoscopic and macroscopic length and time scales. This influence can be due to long-range elastic effects, or to boundary conditions of atomistic (hence, discrete) origin at macroscopic free boundaries. From the viewpoint of physical phenomena, the collective behavior of dislocations determines the plastic deformation of solids; and the motion of steps determines the surface morphology and the lifetimes of nanostructures. From the standpoint of modeling, the atomistic models provide detailed information for the mechanics near the defects; and, on the other hand, continuum models enable predictions at sufficiently large length scales. Hybrid-like theories across scales are also being developed, which, for example, couple simpler models through different length scales, or incorporate useful atomistic detail into continuum models. The invited speakers of this minisymposium will address different aspects of these physical phenomena and modeling approaches, including novel mathematical problems that emerge from them.

Multiscale modeling and simulation for thin film growth. **Russel Caflisch** (University of California, Los Angeles, USA) IC/MT2074/092

This talk presents an application of multiscale modeling and simulation to epitaxial growth of thin films. We describe growth models at three different scales: Monte Carlo atomistic models, island dynamics models and continuum models. The atomistic models include random deposition and hopping of atoms on a lattice. Island dynamics models are coarse-grained in the lateral directions, but are atomistically discrete in the growth direction. They describe step edges and island boundaries as continuous curves. Continuum models are coarse-grained in all directions and describe the epitaxial surface through a continuous height function. Connections between these models are a principal goal of mathematical materials science.

Nonlinear instabilities and shape evolution for single-layer islands. **Joachim Krug** (Universität zu Köln, Germany) IC/MT2006/092

The nonequilibrium evolution of two-dimensional nanoscale structures is a central theme in current surface science. The key theoretical challenge is to bridge the length and time scales between individual atomic processes and the mesoscopic step morphologies that they produce. A highly successful approach to this problem treats the crystal steps as continuous entities, whose dynamics is governed by the interplay between the adatom population on the terraces and the processes at the steps. Depending on whether mass transport occurs predominantly along the step or across the terraces, this results in a local or nonlocal boundary evolution problem. In this talk I report recent progress in the step-dynamical modeling of electro-migration-driven island motion. In the first part the focus is on the local regime, where the problem becomes equivalent to the driven motion of a dislocation loop. The incorporation of crystal anisotropy in the step atom mobility is shown to lead to complex shape evolution scenarios, which include spontaneous symmetry breaking and oscillatory as well as chaotic time dependencies[1]. The predicted behaviors were recently verified in kinetic Monte Carlo simulations of a realistic model for the Cu(100) surface, and quantitative agreement was achieved using suitably parametrized expressions for the

step stiffness and the step atom mobility[2]. In the second part of the talk I consider the nonlocal problem of driven migration of vacancy islands with interior terrace diffusion. In the limit of a strong attachment asymmetry (Ehrlich–Schwoebel effect), a circular island moves at constant speed and remains linearly stable, but a nonlinear instability resulting in the pinch-off of a small island occurs for large driving[3].

Microscopic modelling of the dynamics of crystal surfaces in presence of a macroscopic electric field, and its consequences on spontaneous pattern formation on the nano-scale. **Olivier Pierre-Louis** (Université Joseph Fourier Grenoble, France) IC/MT2151/092

In presence of an electric current in the bulk of a crystal, surface atoms experience a drift, which is called electro-migration. This drift induces a macroscopic mass flux along the surface. Such a mass flux depends on the local geometry, and may redistribute the mass on the surface, thereby creating patterns on the micro or nanometer scale. The understanding of these morphological changes of the surface requires to link the dynamics at different lengthscales: starting from the drift experienced by a single mobile atom at the surface, how can one determine the macroscopic evolution? We will see how the introduction of a intermediate (meso-scopic) lengthscale allows one to handle these changes of scale. The relevant structure at an intermediate lengthscale is the atomic step on the crystal surface. We will first focus on the derivation of the equations of motion of these atomic steps from a microscopic model called a phase field model. We will also discuss how the dynamics of these steps may account for the macroscopic dynamics of the surface.

Crystal surface evolution: from discrete schemes to continuum laws. **Dionisios Margetis** (Univ. Maryland at College Park, USA) IC/MT1027/092

In traditional settings such as fluids and classical elasticity the starting point ("truth") often takes the form of continuum equations for macroscopic variables of interest. But in the modeling of crystalline materials this perspective needs to be changed: The truth is atomistic, or takes the form of discrete schemes, by which evolution laws must be derived at the macroscale. On the basis of this approach predictions can be made for the design, fabrication, and properties of novel solid-state devices. In this talk I focus on recent progress in elucidating the relation of discrete schemes to continuum laws in crystal surface evolution. The governing, discrete equations represent the motion of interacting line defects, "steps" with atomic height. In the appropriate continuum limit nonlinear PDE's are derived for the surface motion. Remarkably, isotropic physical effects at the nanoscale give rise to anisotropies at the macroscale. The PDE's can properly describe the onset of instabilities, particularly "step bunching", by which a continuum description may break down. I will discuss the cases with near- and far-from-equilibrium step kinetics, and progress as well as challenges in the formulation of a continuum theory.

IC/MP56/092: Modeling, analysis and simulation of crystal defects: dislocation and surface step dynamics across the scales. #2

Dislocation dynamics simulations in thin films using the level-set method. **Yang Xiang** (Hong Kong University of Science and Technology) IC/MT1452/092

The control of the density and location of dislocations (line defects) in heteroepitaxial thin film is very important in designing semiconductor-based electronic devices. We have developed a level set method based, three dimensional dislocation dynamics simulation method to describe the motion of dislocations in thin films. The dislocation location is given by the intersection of the zero level sets of a pair of level set functions. This representation does not require discretization and tracking of the dislocation, and handles topological changes automatically. The simulation method incorporates the elastic interactions of the dislocations and the stress fields throughout the film and substrate. Using the above approach, various dislocation motion and interactions within a heteroepitaxial thin film are simulated and analyzed.

Large-scale dislocation dynamics simulations: applications to strength in bulk and finite size systems. **Meijie Tang** (Lawrence Livermore National Laboratory, USA) IC/MT2540/092

This talk will present a front-tracking dislocation dynamics method. The dislocation dynamics method is a numerical tool to quantitatively describe plasticity and strength in crystalline materials. It tracks the collective motion of dislocation line defects and their interactions. It evolves the microstructure formed by the dislocation lines and predicts the yield strength and strain hardening properties. Applications have been made using the LLNL large scale parallel dislocation simulator (ParaDiS) for both bulk and finite sized metallic systems. In these applications, the dislocation dynamics simulations are found to be powerful tools to discover new microstructure [Nature, 440, p1174 (2006)], understand strength in bulk systems, and to explore mechanisms responsible for 'the smaller, the stronger' observation in micro- and submicro- systems in recent experiments.

From electrons to finite elements: a concurrent multiscale approach for metals. **Gang Lu** (CSU Northridge, USA) IC/MT2025/092

We have recently developed a powerful multiscale modeling approach that concurrently couples quantum mechanical calculations for electrons, to empirical atomistic calculations for classical atoms, and to continuum mechanical calculations for finite elements, in a unified description [1]. In specific, the electronic calculations are performed with the plane-wave pseudopotential method based on the density-functional theory (DFT), the classical atomistic simulations with the embedded-atom method (EAM), and the continuum calculations with the Cauchy-Born rule in the local Quasicontinuum (QC) formulation [2]. The multiscale method is implemented in the context of the QC framework with the additional capability to include DFT

calculations for a selection of non-local QC atoms. A novel coupling scheme has been developed to combine the DFT and EAM calculations [3] in a seamless fashion to deal with non-local QC atoms, whereas the local QC atoms are treated in the usual way by the informed finite element calculations. We apply this method to study an edge dislocation in aluminum in the absence and presence of hydrogen impurities at the core. We compare our results to those from the original QC and other atomistic methods. It is clear that our method can provide more accurate descriptions for the defect core properties thanks to the DFT calculations, and yet it can treat much larger systems than standard atomistic and DFT methods thanks to the local QC formulation. If time permits, I will also talk about our recent studies on ductile fracture of Al using the same method.

Generalized Peierls–Nabarro models for curved dislocations. **Pingbing Ming** (Chinese Academy of Sciences), Yang Xiang (Hong Kong University of Science and Technology) IC/MT2058/092

Peierls–Nabarro model is a way of incorporating crucial atomistic features into a continuum framework. Originally it was proposed as a qualitative model for dislocations in solids in order to overcome certain difficulties associated with the continuum theory of dislocations. Subsequent work has greatly improved the accuracy of the model, making it a useful quantitative tool for dislocation structure and dynamics. In this talk, we present a systematic approach for developing accurate Peierls-Nabarro models for general curved dislocations and general crystal structures, in which the dislocation core structure is obtained by the minimization of the total energy including the elastic energy and the energy due to the nonlinear interaction across the slip plane (the misfit energy). We present efficient numerical methods for treating the anisotropic elastic contributions. We also discuss two different ways of developing models for the misfit energy density, the generalized stacking fault energy: one based on symmetry consideration and the other based on direct summation using atomistic potentials. Examples are given for the core structures of straight dislocations and dislocation loops in Al and Cu. I will also talk about the theoretic aspects of this model, in particular, the local and global existence results.

This is a joint work with Yang Xiang (Hong Kong University of Science and Technology), He Wei (Peking University) and Weinan E (PACM, Princeton University).

IC/MP191/093: Dense granular systems: from theory to applications.

Organiser: Lou Kondic (New Jersey Institute of Technology, USA)
Co-organiser: Corey O'Herrn (Yale University, USA)

Dense granular materials appear in a host of applications from the handling of industrial materials to pharmaceutical powders and are relevant to a number of natural phenomena. While significant progress has been reached in understanding dilute systems via kinetic theory and its extensions, progress in the field of dense, slowly sheared systems has been much slower. The issues such as jamming, strong fluctuations of relevant flow properties, history dependence, to name just a few, require development of new research methods. These methods, which vary from discrete modeling via molecular dynamics simulations, extensions of equilibrium statistical mechanics, to development of mesoscale models, reflect multiscale issues which are intrinsic to dense granular systems. The talks in this minisymposium give a wide overview of the current state of the art in this important field, and will cover the topics which will vary from fundamental mathematical issues to applications of granular materials in industrial settings.

Mechanisms for energy dissipation in dense cohesionless granular assemblies: implications for shear banding interpreted as a bifurcation phenomenon . **Antoinette Tordesillas** (University of Melbourne, Australia) IC/MT2819/093

The formation and evolution in two-dimensions of the so-called *persistent shear band* in densely packed assemblies of cohesionless particles are examined using two methodologies: bifurcation analysis within the framework of micromechanical continuum theory and discrete element method (DEM). The former is based on a general micropolar or Cosserat constitutive law, from which several conclusions can be made about the post-bifurcation evolution of the shear band. While many of these conclusions do not depend on the details of the constitutive law, a key advantage of micropolar theory is its link to micromechanically based constitutive laws. It is through micromechanics that a direct link can be made between the mathematical continuum model and observations of the discrete material using particle-based numerical (DEM) and/or experimental techniques.

The motivation for the two-dimensional bifurcation analysis stems from our recent DEM studies which demonstrate that the alternating formation and collapse (via buckling) of load-bearing particle columns or force chains characterize the steady-state (Ṣpersistent T̆) evolution of shear bands, and constitutes the governing mechanism for energy dissipation. Recent experimental findings [1] support these results and further suggest that these mechanisms may be responsible for the observed periodic pattern in the displacements along the shear band axis. The bifurcation analysis shows that a displacement field which is periodic along the shear band axis and displays odd-symmetry across the shear band, leads to a closed form solution for the shear band width. We also show that shear banding is possible in the absence of Cosserat effects Ű in contrast with the one-dimensional bifurcation theory which predicts that shear bands cannot form in the absence of rotational degrees of freedom.

Microstructural studies of dense granular media and their importance to the pharmaceutical industry. **Meenakshi Dutt** (University of Cambridge, UK), James Elliott (University of Cambridge, UK) IC/MT4888/093

Granular materials are agglomerates of particles (10 microns to 10 meters) which interact with one another via dissipative contacts. We will be presenting numerical investigations (using Discrete Element Method (DEM) techniques) of dense granular media generated by gravity settling and constant strain uni-axial compression. The particle size distribution chosen in our study is motivated by X-ray microtomography scans of pharmaceutical excipient compacts (X. Fu *et al.*, Powder Technology 2006). We will discuss the effect of substrate templating (Dutt *et al.*, EPL 2007), and particle size dispersity (Dutt *et al.*, submitted) on the microstructure of these dense packings, and the macroscopic response to strain. These results use the link between the porosity and internal packing structure via a dynamically tesselating algorithm (Benedict *et al.*, Physica A

2007) which calculates the pore network in dense particulate systems. In addition, we will present some predictions of the macroscopic properties of excipient mixtures from investigations of the material microstructure. We will conclude with some discussions on efforts in modeling pharmaceutical powders by using a combination of DEM numerical experiments and X-ray microtomography imaging.

Signal propagation through dense granular systems. **Lou Kondic** (New Jersey Institute of Technology, USA) IC/MT1214/093

We consider propagation of signals through dense granular systems. The results are obtained by relatively large scale (up to 40,000 particles) discrete element simulations in two spatial dimensions. The properties of the signals are used to deduce the basic physical mechanisms of the force and energy transmission. In addition, we discuss the possibility of developing effective models for signal propagation which bridge the spatial scales between micro (grain scale) and meso (hundreds or thousands of grains) description of granular systems. We also discuss the influence of force anisotropy on the characteristics of the propagating signal. Finally, we will present preliminary results regarding signal propagation through dynamic (sheared) granular system.

(For abstract, see session #1 above.)

Jamming, plasticity, and diffusion in dense granular materials. **Robert Behringer** (Duke University, USA) IC/MT1741/093

I will describe recent measurements on systems of photoelastic particles which determine the nature of jamming in a granular material subject to isotropic compression, and then the nature of failure when such a system is subject to shear. Regarding jamming, we obtain data for the pressure , P, the mean contact number per particle, Z, both as functions of the packing fraction, ϕ. We observe a rapid increase in Z as ϕ passes through a critical value. Above ϕ_c, Z and P grow differentially as power-laws in $\phi - \phi_c$ that are in agreement with theory. Regarding plastic failure under shear, we consider the statistical properties of particles within a shear band of a Couette experiment. We consider both locally affine and non-affine behavior. The non-affine displacements characterize local disorder and diffusion, and show gaussian distributions.

Jamming in attractive systems. **Gregg Lois** (Yale University, USA), Corey O'Herrn (Yale University, USA) IC/MT564/093

I will outline recent numerical results on the jamming transition in attractive systems, relevant to cohesive granular materials and powders. As our simulated material is compressed from zero density, we observe three regimes of mechanical behavior that are separated by two second-order critical transitions– percolation and rigidity percolation. This is in contrast to purely repulsive systems that exhibit a single first-order transition. I will give an overview of the mechanical properties in each regime and present measurements of the percolation scaling exponents, which differ from the corresponding lattice values. Although the simulations are athermal, I will demonstrate that the observed behavior also holds for small finite temperatures.

High-density jamming in packings of frictionless aspherical beads. **David Head** (University of Tokyo, Japan) IC/MT1285/093

A convenient, though approximate, means of determining a granular packing's rigidity is to count the number of degrees of freedom of particle motion and constraints of energy invariance, such as fixed interparticle separation. This technique, known as Maxwell counting, seems to give good estimates of rigidity in frictionless spherical and infinite-friction particles. However, the intermediate case of frictionless non-spherical particles has received little attention, perhaps due to a mistaken assumption that it requires non-spherical particles, which are non-trivial to simulate. In fact there is an easier way which is more amenable to efficient simulation, namely to consider spheres of non-uniform mass density such that the particle's centre of mass is displaced from its geometric centre (which still admits non-trivial torque balance equations). Here I will describe initial results from some first simulations employing this approach.

Statistical physics of disordered arrest: from colloidal suspensions to dense granular systems. **Matthias Sperl** (Duke University, USA) IC/MT1622/093

A dense suspension of colloidal hard spheres shows slow and stretched relaxation dynamics over many orders of magnitude in time. It will be shown how this slow dynamics – i.e. the experimental mean-squared displacement – can be fitted and interpreted by a microscopic theory. Changes to the elastic hard-sphere scenario shall be discussed when one introduces (1) attractive interaction, (2) additional soft-core repulsion, and (3) dissipation. Some features found for the dynamics can be used to interpret certain aspects of static granular systems.

IC/MP598/096: Mathematical modeling and numerical analysis of fracture phenomena.

Organiser: Kohji Ohtsuka (Hiroshima Kokusai Gakuin University, Japan)
Co-organiser: Naoshi Nishimura (Kyoto University, Japan)
Co-organiser: Victor Kovtunenko (Universität Graz, Austria)

Mathematical researches on fracture phenomena are of interest to note that the singularity at the edge of cracks generates the crack extension force. The coefficients of singular term are called stress intensity factors in fracture mechanics. This field is constructed of many problems; i.e., crack problems, quasi-static fracture, dynamic fracture, brittle fracture, fatigue fracture, crack path, crack arrest, etc. The purpose of our mini-symposium is to clarify these problems from mathematical viewpoint and to give numerical analysis to simulate fracture phenomena based on mathematical modeling.

However under general situation, crack problem still remain even though crack problem is simplest in this field. Suggested speakers will talk the latest researches on crack problems. In numerical analysis, large scale computations are required for solving complicated fracture problems which include singularities. Latest research results on this topic will be presented by N. Nishimura. In fracture problems, there are many proposals estimating fracture phenomena from mechanical viewpoint.

However, they are independent of each other, and moreover some of them are contradictory. K. Ohtsuka and V. Kovtunenko think that Griffith's energy balance theory will provide basic principle on mathematical modeling of fracture, and Ohtsuka proved that the crack extension force depends only on singularity at the edge of crack in the case of 3-D quasi-static fracture with a crack surface defined by 2-D manifold with the edge under Griffith's principle. In this mini-symposium, we also study Griffith's principle and its modification. Kovtunenko will talk optimization approach to quasi-static crack propagation under non-penetration condition proposed by A. Khludnev.

On inverse crack problems in elastostatics. **Hiromichi Itou** (Gunma University, Japan), Masaru Ikehata (Gunma University, Japan) IC/MT1048/096

In solid mechanics, nondestructive testing has been an important technique in gathering information about unknown cracks, or defects in material. From a mathematical point of view, this is described as an inverse problem of partial differential equations, that is, the problem is to extract information about the location and shape of an unknown crack from the surface displacement field and traction on the boundary of the elastic material. By using the *enclosure method* introduced by Prof. Ikehata we can derive the extraction formula of an unknown linear crack from a single set of measured boundary data. Then, we need to have precise properties of a solution of the corresponding boundary value problem; for instance, an expansion formula around the crack tip. In this talk we will consider the inverse problem concentrating on this point. This research is a joint project with Prof. Ikehata of Gunma University.

Crack detection using topological sensitivity analysis. **Samuel Amstutz** (Université d'Avignon, France), Mohamed Masmoudi (Université Paul Sabatier Toulouse III, France), Imen Horchani (Ecole Nationale d'Ingenieurs de Tunis, Tunisia) IC/MT776/096

The topological sensitivity analysis consists in studying the behavior of a given shape functional with respect a perturbation of the topology of the domain. In general, the nucleation of a small spherical hole is considered. I will show that the concept of polarization tensor allows to extend the analysis to arbitrarily shaped holes and even cracks. Using an appropriate functional, the computation of this sensitivity leads to an efficient and fast method to detect and localize cracks in a domain from boundary measurements. Some numerical experiments in this context will be presented.

Mathematical modeling of stable quasi-static crack extension by extended Griffith energy-balance theory. **Kohji Ohtsuka** (Hiroshima Kokusai Gakuin University, Japan) IC/MT931/096

Griffith's approach to fracture mechanics is very powerful, and there are many extensions and modifications of Griffith's work. Here, upon Griffith's idea, we derive a *criterion for stable and unstable crack extension* of a crack with the shape of arbitrary surface Σ with the edge $\partial\Sigma$ in three-dimensional solids subjected to arbitrary loads. The crack extension process is considered to occur in a quasi-static manner such that inertial effects may be neglected. Therefore, when we refer to time t we use it as a parameter that delineates the history of sequence of events such as loading $\mathcal{L}(t)$ and crack extension $\Sigma(t)$. Under a loading $\mathcal{L}(t)$, if a virtual crack extension $\{\Sigma(t)\}$ is given in the form of the sequence of surfaces with the edge, then we can get the displacement vector as the weak solution of the variational problem defined on $\Omega_{\Sigma(t)} = \Omega \setminus \Sigma(t)$. Here Ω denotes the bounded domain with smooth boundary and is assumed satisfying $\Sigma(t) \subset \Omega$. Griffith's energy balance theory is so that it is applicable only when $\mathcal{L}$ remains constant during crack extension. However, in general, the released energy increases as long as $\mathcal{L}$ remains constant. For this, to consider the stopping of crack extension, we need the modification for the energy release rate to be applicable under varying loads. With this modification, driving new formula $\mathcal{F}_{\Sigma(\cdot)}(t)$, we can extend Griffith's energy balance theory in consideration of second expansion of energies and crack extension resistance with respect to time. We now define that $\Sigma(t)$ is *unstable*, if $\mathcal{F}_{\Sigma(\cdot)}(t) > 0$ for all $t > 0$. We can also derive the criterion of stability.

Quasi-static evolution in brittle fracture based on local minimization. **Christopher Larsen** (Worcester Polytechnic Institute, USA) IC/MT3904/096

Based on Griffith's criterion for crack growth, a method was recently proposed for determining crack paths by taking continuous-time limits of discrete-time variational problems. This has been successfully carried out, but an important difference remains between these solutions and Griffith's model. I will explain the method and the main issues in its implementation, and then describe the remaining gap and some efforts to remove it.

Optimization in constrained crack problems. **Victor Kovtunenko** (Universität Graz, Austria), Alexander Khludnev (Lavrentyev Institute of Hydrodynamics, Russian Federation) IC/MT633/096

Following the optimization approach to brittle fracture, we consider evolution of a crack in a domain as solution of the global problem of minimization of the total potential energy with respect to shape variables. For instance, the shape optimization problem is well-posed with respect to the length-parameter of the crack, that describes its quasi-static propagation by delamination process.

The necessary ingredients include:

Kinematic description of crack evolution by given a-priori vector of the velocity field can be given in two ways: constructing one-to-one coordinate transformation between domains with cracks with the help of nonlinear ODE, or by implicit surfaces solving a linear transport equation.

Modeling of equilibrium of solids with crack is given in the framework of variational formulation of the static problem, accounting conditions of non-penetration between the crack surfaces in the admissible set, which results in constrained crack problems.

The primal-dual shape sensitivity technique of is applied to describe kinematic characteristics of the crack problems with respect to regular perturbations of parameters of the crack shape with given velocity vector field, in particular, to find the energy release rate at the crack tip by means of the first directional derivative.

For numerical optimization, based on the generalized differentiability property, a semi-smooth Newton method is proposed

in the form of primal-dual active-set methodin as the efficient numerical technique for solution of constrained minimization problems, in particular with cracks, due to the property of its unconditional global and, moreover, monotone convergence.

The global optimization is realized in a constructive way on the set of extremal points of the cost functional by the path-following methods, which use the differentiability property of the reduced energy function. Numerical examples present quasi-static propagation of cracks during the delamination process in composite, based on the refinement of the Griffith fracture law in frame of the optimization approach.

Dynamical crack propagation in a 2D elastic body, the out-of-plane state. **Anna-Margarete Sändig** (Universität Stuttgart, Germany), Serge Nicaise (Université de Valenciennes, France), Adriana Lalegname (Universität Stuttgart, Germany) IC/MT981/096

We discuss the propagation of a running crack under shear waves in a rigorous mathematical way for a simplified model. This model is described by two coupled equations in the actual configuration: a two-dimensional scalar wave equation in a cracked bounded domain and an ordinary differential equation derived from an energy balance law. The unknowns are the displacement fields $u = u(y,t)$ and the one-dimensional crack tip trajectory $h = h(t)$. We handle both equations separately, assuming at first that the crack position is known. Existence and uniqueness of strong solutions of the wave equation will be studied and the crack-tip singularities will be derived under the assumption that the crack is straight and moves tangentially. Using an energy balance law and the crack tip behaviour of the displacement fields we finally arrive at an ordinary differential equation for $h(t)$, called equation of motion for the crack tip. We demonstrate the crack-tip motion with the corresponding nonuniformly crack speed by numerical simulations.

IC/MP201/096: Computational aspects in finite electro- or magneto-elasticity.

Organiser: Paul Steinmann (TU Kaiserslautern, Germany)
Co-organiser: Gérard Maugin (Université Pierre et Marie Curie, France)

In the recent years various novel materials have been developed that respond mechanically to the application of electrical or magnetical loading by large strains. Examples are the classes of so-called electro-active and magneto-sensitive polymers. Certainly these materials are technologically very interesting; e.g., for the design of actors in mechatronics or in the area of artificial soft tissue biomechanics.

The minisymposium thus focuses (i) on the modelling of electro- and magneto-elastic materials within the setting of geometrically nonlinear continuum-electro-dynamics (often spezializable to the case of electro- or magneto-elasto-statics) and (ii) in particular to the corresponding computational setting. Thereby a highly nonlinear coupled problem for the deformation and the electric or magnetic (scalar or vector) potential has to be solved, that is only amenable to computational solution techniques.

As an interesting and probably less known aspect the minisymposium highlights also the theoretical and computational treatment of various defects (like e.g., cracks or inclusions), for this example of a coupled multiphysics problem. The study of configurational continuum physics renders a valuable tool for the analyst in order to examine further properties of the solution which would otherwise be hidden.

Simulation of poly-crystalline ferro-electrics based on discrete orientation distribution functions. **Jörg Schröder** (Universität Duisburg-Essen, Germany) IC/MT2154/096

Ferro-electric materials can be found in a wide range of applications in smart materials; e.g., vibration reducing sensors or fuel injection systems. A special characteristic feature of these materials is the appearance of a spontaneous polarization in a certain temperature range. This polarization can be reversed by an applied electric field of sufficient magnitude. The resulting nonlinear material behavior is expressed by characteristic dielectric and butterfly hysteresis loops. In case of single crystals these effects are correlated to the structure of the crystal and especially to the axis of the spontaneous polarization.

The anisotropic material behavior is modeled within a coordinate-invariant formulation for an assumed transversely isotropic material, see [1,2]. The anisotropic response of the material is governed by isotropic tensor functions which depend on a finite set of invariants. In order to model the nonlinear material behavior a switching surface is defined and evolution equations for the remanent quantities are derived. For the consideration of the polycrystalline material behavior we start with a representative meso scale, where the domains consist of unit cells with equal spontaneous polarization. The main equations of the mesoscopic boundary value problem are the balance of momentum and the Gauss law respectively. For the derivation of the boundary conditions on this scale we consider a generalized macrohomogenity condition which equates the macroscopic and the mesoscopic electromechanical work. In this investigation we obtain the macroscopic polycrystalline quantities via a simple homogenization procedure, where discrete orientation distribution functions are used to approximate the different domains. The resulting hysteresis loops for a ferroelectric ceramic are discussed and some numerical examples are presented.

Numerical simulation of electro- and magneto-elasticity. **Duc Khoi Vu** (TU Kaiserslautern, Germany), Paul Steinmann (TU Kaiserslautern, Germany), Gunnar Possart (TU Kaiserslautern, Germany) IC/MT3327/096

Electro- and magneto-sensitive elastomers belong to the class of smart materials that exhibit large displacement and change their mechanical behavior in response to the application of electric or magnetic fields and have been the subject of many researches in the last few years due to their interesting application including robotic arms that are actuated by artificial muscles, adaptive tuned vibration absorbers, stiffness tunable mounts and suspensions and automotive bushing, see for example [1-5].

Besides the various difficulties facing researchers in their effort to produce effective systems driven by electro or magneto-sensitive elastomers, due to their nonlinear electro- and magneto-mechanical coupling behavior the modelling and simulation of these materials is also a challenging task. The governing equations and some simulations of the electroelastic and magnetoelastic coupling problems were addressed in [5-9]. Based on these previous studies, the numerical simulation of nonlinear electro- and magneto-elasticity is addressed

in this work.

The mechanics of interfaces between elastic dielectrics and application towards cracks in piezoelectrics. **Andreas Ricoeur** (TU Bergakademie Freiberg, Germany), Meinhard Kuna (TU Bergakademie Freiberg, Germany) IC/MT4030/096

Interfaces between dielectric solids can be found in laminated structures or composite materials. Dielectric interfaces are also present at the boundaries between solid bodies and fluids or a vacuum. Likewise, the faces of a crack in a dielectric material are interfaces between a solid and vacuum, air or an insulating liquid. If either an electric load is imposed on the aforementioned systems or the bodies exhibit physical properties coupling mechanical and electrical fields, forces and related displacements are induced at the interfaces as well as inside the body. Although sometimes small compared to the effect due to mechanical loads, these forces should be included into a comprehensive analysis of the mechanics of dielectrics.

The theoretical background is based on thermodynamical considerations of linear dielectrics and piezoelectrics including inhomogeneities and defects. Material or configurational forces are calculated from the explicit space-variance of thermodynamical potentials. The forces acting on an interface are derived likewise, introducing the MAXWELL tensor of electrostatics. Here, different approaches are discussed. The results are applied to cracks in piezoelectric ceramics. Considering the crack slit as a medium of finite dielectric permittivity, the boundary conditions on the crack faces are formulated both dielectrically and thermodynamically consistent. Calculating the J-Integral, crack surface loads have to be taken into account. In doing so, the classical contour integration is replaced by a simple jump term. Depending on the modeling of the crack faces, i.e. electrical and mechanical boundary conditions, the approach is only exact for arbitrary cracks if a simplified model for crack surface tractions is applied. In all other cases it is shown to be a good approximation. The influence of different crack face boundary conditions on fracture mechanics quantities is demonstrated by means of analytical examples.

Continuum thermodynamic modeling and simulation of electromagnetic metal forming processes. **Bob Svendsen** (Universität Dortmund, Germany), Jaan Unger (Universität Dortmund, Germany) IC/MT2321/096

The purpose of this work is the formulation and application of a continuum thermodynamic approach to the phenomenological modeling of a class of engineering materials which can be dynamically formed using strong magnetic fields. This is carried out in the framework of a thermodynamic, internal-variable-based formulation in which the deformation, temperature and magnetic fields are in general coupled. This coupling takes the form of the Lorentz force as an additional supply of momentum, and the electromotive power as an additional supply of energy, in the material. In the current approach, the basic thermomechanical field relations for mass, momentum and moment of momentum are obtained from the total energy balance via invariance, and completed by Maxwell's field equations. The constitutive formulation is based on the exploitation of the Müller-Liu entropy principle, here for the case of isotropic thermoelastic, viscoplastic material behaviour. The resulting reduced constitutive and field relations and restrictions are then applied to the modeling and simulation of high-speed electromagnetic forming of metal tubes and sheet metal. The finite-element numerical simulation here is based on a staggered solution scheme involving a Lagrangian mesh and stabilized solid-shell elements for the workpiece together with an ALE-based formulation utilizing Nédélec elements for the electromagnetic part of the problem. Simulation examples will be presented.

A variational formulation for magneto-active elastomers based on the total-energy approach. **Roger Bustamante** (University of Glasgow, UK) IC/MT1611/096

This presentation focuses on variational formulations of a magneto-active elastomer completely surrounded by free (vacuum) space [1]. The free space is considered finite, with an applied magnetic field or magnetic induction vector as the far field boundary conditions. The entire surface of the body is in direct contact with the free space, additionally a mechanical load is applied over a portion of the surface. No displacement constraints are considered.

For this boundary value problem two equivalent variational formulations are proposed, which are formulated in terms of the *total energy function* Ω introduced by Dorfmann and Ogden [2,3]. One of these formulations is based on the use of the displacement field and the magnetic scalar potential (for the magnetic field), the second equivalent formulation is based on the magnetic vector potential (for the magnetic induction) in addition to the displacement.

Important questions regarding the use of the *Maxwell stress* for the boundary conditions are discussed.

Equivalent governing equilibrium equations for nonlinear magneto-elastic solids. **Luis Dorfmann** (Tufts University, USA), Roger Bustamante (University of Glasgow, UK) IC/MT2244/096

In recent years there has been considerable renewed interest in electromagnetic theories of materials capable of large elastic deformations. This is motivated by the need for accurate constitutive equations to support the use of so called 'smart' materials for the development of a number of industrial devices.

The theoretical foundations for a continuum deforming in the presence of an electromagnetic field are given, for example, by Truesdell and Toupin [9], Brown [1], Eringen and Maugin [5] and Kovetz [7]. More recent theoretical works are those by Steigmann [8], Kanakanala and Triantafyllidis [6], Dorfmann and Ogden [3,4] and Bustamente *et al.* [2].

In this presentation we give an overview and evaluate alternative formulations of the governing equilibrium equations for nonlinear magnetoelastic deformations of magneto-sensitive solids. We highlight differences (but in principle equivalent) formulations and show possible restrictions imposed by the magnetic field equations on the form of the constitutive laws. In particular, we provide a detailed comparison of our formulation with the one given by Steigmann [8], Kanakanala and Triantafyllidis [6] and Brown [1].

Surface stability of nonlinear magneto-elastic solids. **Melanie Ottenio** (Université Bordeaux I, France) IC/MT3283/096

Nonlinear magnetoelastic solids offer interesting industrial applications because their damping abilities can be tuned by adequate outside magnetic fields. Here, we propose to derive the equations governing the deformations of infinitesimal disturbances superimposed onto large static fields in magnetoelasticity. The coupling between the equations of mechanical equilibrium and Maxwell's equations complicates the formulation of incremental elasticity. However, our approach is based on Dorfmann and Ogden's work, which allows to obtain the governing coupled equations in a form similar to the form of the governing equations of nonlinear elasticity. Then, we propose to look for the conditions of surface stability when the solid is held in plane strain and a magnetic induction vector is applied along the normal to the surface. How large can be the applied magnetic field and how much can we pre-strain the half-space before reaching the bifurcation criterion are the questions that we try to answer.

A kinetic Monte-Carlo study illustrating control of morphological instability during directional epitaxy. **Michael Saum** (University of Tennessee, USA), Tim Schulze (University of Tennessee, USA) IC/CT2514/092

We consider a Kinetic Monte Carlo (KMC) model of directional epitaxy for both single and multi-species growth. In particular, we present a model for the continuous processing of thin film deposition on a moving substrate. Instabilities in the morphology of the resulting surface are initiated by the presence of the Erhlich-Schwoebel barrier and result in the self assembly of structures with different characteristics. We illustrate how these morphological changes can be controlled by varying parameters such as temperature, the substrate pulling velocity, and deposition flux profile.

Gradient second-order interphase-layer theory of continuous media with micro-structures. **Sergey Lurie** (Russian Academy of Sciences, Moscow), Natalia Tuchkova (Russian Academy of Sciences, Moscow) IC/CT917/092

The interphase layer theory is developed on the base of the continuum media with conserved dislocations [1]. The rigorously formulated continuous media models with microstructure are proposed. Correctness of the developed models is justified by application of the kinematic variational principle based on the consistent formal description of the media kinematics and formulation of the kinematic relations for the media of a different complexity, as well as on the construction of the relevant potential strain energy with the use of the Lagrangian multipliers procedure. The special attention is paid to the analysis of kinematic relations since in the framework of variational description the kinematics of medium fully defines the system of internal volumetric and surface interactions of the body under study. The set of constitutive relations is derived and the corresponding consistent boundary-value problems are formulated. For the first time, the interpretation of all physical characteristics that are responsible for non-classical effects is proposed, and the entire spectrum of adhesion mechanical parameters is described. The general model of continuous media proposed in the present paper is a first rigorous theoretical model that allows to analyze various particular scale effects, e.g., cohesive interactions, surface effects (surface tensions, wettability, capillarity etc.) both in the volume and on a surface within the unified continuum description. By the model it was found that these effects could help to understand-predict macro-micro mechanics of the material, if the boundary conditions and phase effects are modeled across the length scales. The prediction methodology and modeling tools have been developed for numerical simulations and analysis of the stress-strain-stress and mechanical properties across the length scales [2-5]. 1. Mathematical problems for piezoelectric–metallic composites. **David Natroshvili** (Georgia Institute of Technology) IC/CT1069/092

We study the following mathematical problem related to engineering applications: Given is a three-dimensional composite consisting of a piezoelectric (ceramic) matrix with metallic inclusions (electrodes). We derive a linear model for the interaction of the corresponding 4-dimensional thermoelastic field in the metallic part and 5-dimensional thermoelectroelastic field in the piezo-ceramic part.

The main difficulty in the modelling is to find appropriate boundary and transmission conditions for the composed body. The mathematical analysis includes then the study of existence, uniqueness and regularity of the resulting elliptic boundary-transmission problem assuming the metallic and ceramic materials occupy smooth or polyhedral domains.

With the help of the indirect boundary integral equations method we reduce the complex transmission problem to the equivalent strongly elliptic system of pseudodifferential equations involving pseudodifferential operators on manifold with boundary. The solvability and regularity of solutions to these boundary integral equations and the original transmission problem are analyzed in Sobolev-Slobodetski (Bessel potential) H^s_p and Besov $B^s_{p,t}$ spaces. This enables us to investigate also stress singularities which appear near zones, where the boundary conditions change and where the interface meets the exterior boundary. We show that the order of the singularity is related to the eigenvalues of the symbol matrices of the corresponding pseudodifferential operators and study their dependence on the material constants of the composite.

Nanoscale modeling of the elastic contact between a rigid indenter and an elastic half-space. **Dan Dumitriu** (Institute of Solid Mechanics, Romania) IC/CT484/092

In the theory of elasticity, mixed boundary value problems arise naturally in elastic contact problems. This paper deals with the elastic contact between a rigid indenter of known tip geometry and an elastic half-space. Indentation is a method used to analyse the characteristics of materials related to different mechanical processes, such as: fracture, defect nucleation, adhesion, friction, wear. Here the indentation problem is studied at the nanometric scale, where classical continuum mechanics can no more accurately model the elastic contact. New coupled atomistic–continuum methods must be used to solve the elastic nanocontact problem.

At the nanometric scale, EringenŠs nonlocal theory describes better than classical (local) continuum mechanics methods the long-range interactions among the particles in materials. In the classical theory, the balance laws are valid for every part of the body, no matter how small it may be, and the localization condition yields to the vanishing of integrants in the integrals. In the nonlocal theory, this assumption is abandoned, but the localization is still possible with the aid of certain localization residuals, which must integrate to zero. These residuals are the effects of all other points of the body on one point of the body, that means the residuals are the long-range effects of all points at which the balance laws are localised.

The nonlocal formulation is numerically solved using a finite elements code written in C. One has to solve a linear equations system of big dimensions, without dealing with a sparse matrix as in local approaches.

The nanoindentation example presented in the paper concerns a flat punch of arbitrary shape. For parabolic, circular, elliptic and square punches, closed form exact solutions for contact pressures and penetration are obtained, using SneddonŠs dual integral equations. The contact pressures are bounded and continuous functions inside and on the boundary of the contact domain. The availability of exact solutions for these particular flat punches permits to validate the proposed numerical resolution of the nonlocal formulation. Once the numerical code validated, it can be used for any arbitrary shape of the flat punch.

Materials with inter- and intralaminar defects under in-plane compression. **Igor Guz** (University of Aberdeen, UK), Maria Kashtalyan (University of Aberdeen, UK) IC/CT1169/092

Various types of inter- and intralaminar defects may occur in layered materials during the fabrication process or in-service. Interlaminar defects include cracks, zones of non-adhesion, reduced adhesion and slippage, and similar imperfections, while intralaminar defects could be cracks, voids, porosity etc.

When a layered material is compressed along the layers, fracture due to interlaminar defects cannot be predicted using the classical Griffith-Irwin criterion or its generalisations, and therefore fracture due to mechanisms, specific to heterogeneous materials, needs to be considered. One of such mechanisms is internal instability, i.e. the loss of stability in the microstructure of the heterogeneous material. Here the internal instability of non-linear layered materials with inter- and intralaminar defects undergoing finite (large) deformations is investigated. For cleavage-type delaminations, the upper and the lower bounds for critical load are established. The bounds are based on the exact analytical solutions for 3-D problems considered within the model of piecewise-homogeneous medium.

The presence of intralaminar defects is accounted for by replacing the layers with defects with equivalent homogeneous ones with appropriate effective properties. To take account of the in-situ constraint of the neighbouring layers on the effective properties of a particular layer with defects, it is suggested to use the Equivalent Constraint Model of the damaged layer. Previously, the model was successfully used to predict effective properties of cracked layers in fibre-reinforced composite laminates.

The effect of the different types of inter- and intralaminar defects, layer thickness and stiffness on the lower and the upper bounds is examined for a number of non-linear models of materials under various kinds of loading. The obtained results show that the bounds present a good estimation.

Newton's coefficient of restitution at the macro- and nano-scales. **Graham Weir** (Industrial Research, Ltd., New Zealand) IC/CT2077/095

Newtons Coefficient of Restitution, for low velocity impacts between macroscopic rigid-plastic identical spherical particles, depends primarily on the initial relative velocity, Youngs Modulus, particle size and the plastic yield stress. Surface tension becomes important for impacts between nano-scale particles. The major implications of surface tension for impacts at the nano-scale are discussed, and some approximations are possible by referring the nano-scale parameters down to the atomic scale. New results are presented on the order of magnitude for the yield strength of nano-scale material particles.

IC/CTS4629/09: Theoretical topics incl. granular material.

Analysis and simulation of dune evolution: from a dynamical-system perspective. **Serina Diniega** (University of Arizona, USA), Karl Glasner (University of Arizona, USA) IC/CT3028/093

Dunes are common landforms, developing whenever there is a source of granular material, wind of sufficient strength to move this material, and an "obstacle" to induce initial accumulation. They have been found on Earth, Mars, and Titan.

The aim of this research is to formulate a simple BCRE-type model of dune genesis, behavior, and morphology, through numerical simulation and Dynamical Systems analysis. Currently, the model considers a two-dimensional dune field. Coupled partial differential equations govern the exchange of sand between a "static sand" layer (the dune) and a "moving sand" layer. In the equations, simple functions average together the sand transport processes (saltation, reptation, creep) to yield erosion and deposition amounts. The moving layer advects, and diffusion terms account for smoothing processes (air turbulence, avalanching).

Standard Dynamical Systems analysis has been done to nondimensionalize the equations, determine stability about the steady-state system (flat plane of sand with constant flux), and find characteristic scalings of the system. With reasonable parameter values, long-wavelength instabilities were found. These instabilities are the cause of the formation and growth of dune-type structures.

The model has also been numerically simulated, through a two-step process which considers the uncoupled nonlinear parts first. Initial conditions were chosen as random perturbations about the steady-state solution, and periodic boundary conditions were employed to keep the total mass of the system constant. Both random and sinusoidal initial conditions were found to quickly coalesce into a few piles of sand, which moved across the simulation box. As the simulation progressed, the piles continued to coalesce until one large pile of sand remained and moved at a uniform speed across the simulation box.

Numerical analysis of micro-stress evolution in dual-face polycrystals. **Jan Ocenasek** (TU München, Germany), Christian Krempaszky (TU München, Germany) IC/CT3624/009

Wide range of mechanical and thermal treatments of materials and components are commonly applied to obtain characteristic mechanical properties. Identification of macroscopic residual stresses caused by those treatments is essential to prevent undesirable distortion of further machined components or to predict reliably the stress state of parts during working time.

Neutron diffraction brought several advantages in investigation of residual stresses, but its application is limited for example by finite size of excited volume or by microstructural features of investigated material like multiface structure, texture, grain size, precipitations and upcoming interphase and intergranular microstresses. In literature experimental results that are not consistent with considerations of mechanical equilibrium have been explained up to now by assuming nonhomogeneously distributed and anisotropic lattice parameters [Dye D. et al., Metall. and Mat. Transactions 2004].

A numerical study analysing the evolution of stresses in polycrystalline microstructure under several loading conditions is presented. The aim of this study is to better understand the impact of intergranular and interphase stresses on diffraction-based residual stress analysis.

Computer simulations based on representative volume element using periodic boundary conditions (to reduce high computational costs) are presented. Particular grains follow the continuum crystal plasticity constitutive law to capture both elastic and plastic anisotropy of single crystals structures. Voronoi tessellations are used to mimic real spatial morphology of polycrystals. Results are discussed together with experimental data of neutron diffraction measurements.

Newton-like solver for elastoplastic problems with hardening and its local super-linear convergence. **Peter Gruber** (Universität Linz, Austria), Jan Valdman (Universität Linz, Austria) IC/CT3030/096

We discuss a solution algorithm for quasi-static elastoplastic problems with linear hardening. After discretization in time, such problems can be discribed by the minimization of a functional, which depends on the plastic strain non smoothly, and on the displacement and a hardening parameter smoothly. For the most relevant models of hardening, the minimizers for the plastic strain and the hardening parameter can be calculated explicetely. By substitution, one obtains a minimization functional which depends on the displacement only.

A theorem of J. J. Moreau from convex analysis states, that this functional is differentiable and the derivative can be computed explicitely. This is a non trivial result, since the original functional depends non smoothly on the plastic strain, and the plastic strain minimizer depends non smoothly on the displacement.

However, the second derivative of the energy functional does not exist. As a remedy, we utilize a concept of slanting functions, which was recently developed by X. Chen, Z. Nashed and L. Qi. A Newton-like method, exploiting slanting functions of the energy functional's first derivative, is proposed. The local super-linear convergence of this method is shown in the FE-discrete case, and sufficient regularity assumptions are formulated, which imply the local super-linear convergence also in the spatially continuous case.

Time integration of inelastic material models exhibits an order reduction for higher-order methods - can this be avoided?. **Charlotte Kuhn** (TU Darmstadt, Germany), Bernhard Eidel (TU Darmstadt, Germany) IC/CT2302/096

For the numerical treatment of inelastic material behavior within the finite element method a partitioned ansatz is standard in most of the software frameworks; the weak form of equilibrium is discretized in space and solved on a global level, whereas the initial value problem for the evolution equations of internal state variables is separately solved on a local, i.e. Gauss-point level, where strains, derived from global displacements, serve as input, [1].

Applying higher order methods ($p > 2$) to the time integration of plasticity models, an order reduction is reported, where Runge-Kutta schemes have shown hardly more than order two at best, [2].

In the present contribution, we firstly analyze for the ODE case of viscoelasticity the reason for order reduction and in doing so focus on the crucial role of strain approximation for multi-stage methods in time integration. Next, we extend our considerations to the DAE case of plasticity, where the switching point detection must additionally be considered for the generation of consistent initial data. We specify our general procedures for both types of constitutive behavior to Runge-Kutta methods of Radau IIa class and show their improved performance in representative numerical examples.

Configurational forces in a micro-cracked body. **Malika Bongué Boma** (Laboratoire Central des Ponts et Chaussées, France), Maurizo Brocato (École Nationale Supérieure d'Architecture de Versailles, France) IC/CT4380/096

A model assessing the behaviour of a micro-cracked body under slow mechanical loading is presented.

Calling upon the theory of microstructure, the kinematics of the domain is enriched thanks to a variable characterising size and orientation of the crack field. Balance equations and boundary conditions governing the evolution of its dual variables are determined.

The crack field can propagate following the macromotion i.e. the latent microstructure is determined by the macroscopic gradient of deformation. However we deal with a configurational evolution that changes the integrity of the body: considering a non dissipative movement, the crack doesn't recover its initial size after load removing.

We therefore divide the evolution of the body in two fictive evolutions:

- Propagation of the micro-cracks: the body evolves from the reference configuration to an intermediate one without any movement of its material points. We hence define a configurational parameter characterising the propagation velocity of the crack field.
- Deformation of the body: it evolves from the intermediate to the current configuration following the macromotion.

We determine the new balance equations and boundary conditions governing those two evolutions. Some new stresses appear in the model. They will be called micro-configurationnal because they are configurational forces associated to a microstructural variable. Those four stresses are dual to the first and second gradient of deformation and dual to the the crack propagation parameter and its gradient.

Non-local boundary-value problem for a system of singular differential equations and applications to cusped prismatic shells. **George Jaiani** (Tbilisi State University, Georgia) IC/CT4427/015

The paper deals with a system of singular partial differential equations of the first and second order arising in the zero approximation of I.Vekua's hierarchical models of prismatic shells [1], when the thickness of the shell varies as a power function of one argument and vanishes at the cusped edge of the shell [2], [3]. For this system of special type a nonlocal boundary value problem in a half-plane is solved in the explicit form. The boundary value problem under consideration corresponds to stress-strain state of the cusped prismatic shell under the action of concentrated forces and moments.

Deformations of wrinkled fiber-reinforced membranes. **Elena Shmoylova** (Tufts University, USA), Luis Dorfmann (Tufts University, USA) IC/CT4507/015

In this presentation we discuss wrinkling of non-linearly elastic membranes. Some aspects of this phenomenon for isotropic and anisotropic membranes have been investigated in the past and results are available in the literature. However, the development of wrinkled regions in non-linearly elastic membranes reinforced with one or two families of fibers, to the best of our knowledge, has not been investigated.

We consider the modeling of wrinkling of non-linearly elastic membranes as an initial step to improve our understanding of the development and the structural response of many biological and native tissues, for example, wrinkling formation in the human skin. Since most biological tissues have a complex anisotropic structure and often contain naturally formed fibers (e.g. collagen fibers), fiber-reinforced membranes deserve special attention.

We determine wrinkled regions for different geometric layouts, which can be described by the membrane theory. The objective of the work is to determine optimal fibers' orientation that minimizes the wrinkled regions for given boundary conditions. Also, we show that for selected geometric configurations and given boundary conditions, a fibers' orientation may be found which has no effect on the overall wrinkle formation, i.e. the structural response is not influenced by the presence of the reinforcing fibers. We believe that these findings may provide an interpretation of how and why some native fiber-reinforced tissues grow and remodel.

Buckling of a spherical shell embedded in an elastic substrate with a uniaxial stress field at infinity. **Gareth Jones** (University of Oxford, UK), Jon Chapman (University of Oxford, UK), David Allwright (University of Oxford, UK) IC/CT4759/015

For many underwater applications, tiles made of a certain composite material are used to minimise the reflection coefficient of submerged bodies. This material consists of a rubber substrate, containing gas-filled microspheres which are a few microns in diameter. In their application, the tiles are compressed uniaxially, which induces a uniaxial stress field in the material. This will cause the embedded shells to buckle, thus softening the material. To examine this phenomenon we consider the linear elastic problem of an isolated embedded shell, with a uniaxial stress field at infinity in the substrate. The critical stress for buckling is determined by the Rayleigh–Ritz method, expanding the buckled shell displacement in a series of Legendre functions. This numerically-determined critical stress is then examined in the limit as the thickness ratio of the shell tends to zero, with the aid of WKB analysis. We obtain analytic expressions for the critical stress and buckling pattern in this limit.

On kinematics of a parallel robot used for the minimally-invasive surgery. **Doina Liana Pisla** (Universitatea Tehnicã Cluj-Napoca, Romania), Nicolae Plitea (Universitatea Tehnicã Cluj-Napoca, Romania), Calin Vaida (Universitatea Tehnicã Cluj-Napoca, Romania), Adrian Pisla (Technical University Cluj-Napoca, Romania) IC/CT807/095

Robotic systems have been developed in every field where a further progress was constricted due to the human limitations in terms of speed, precision, fatigue, repeatability, strength, etc. Parallel robots offer a higher stiffness and smaller mobile mass than serial robots, thus they allow faster and more precise manipulations. The problems concerning parallel structures kinematics are usually more complicated than for the serial structures. One of the pioneer fields for robots is their assimilation in surgery, especially in minimally invasive procedures which aim the treatment of a disease with minimum damage to healthy tissue and suffering for the patient. The paper presents the geometric and kinematic model of an innovative parallel structure for the manipulation of surgical instruments in minimally invasive surgery. The parallel architecture

has been chosen for its superiority in precision, repeatability, stiffness, higher speeds and occupied volume. Another important feature is the smaller working volume of such a structure, which in this case is a supplementary safety measure, which is provided by the structure itself. The equations, which model the geometric and kinematic models, are pointed out for this robot based on its mathematically determined functional parameters. The results of the kinematical modeling are systematically presented and lead to the facile solving of the parallel structure.

For this new structure the authors will develop a haptic feedback system which will eliminate the one of the biggest complains of the doctors referring to the lack of tissue feeling.

This system will allow doctors, which manipulate the robot to actually feel the resistance of the tissues and organs of the patient thus having a second control besides the visual one. The cheaper structure will allow a wider spread or the robot in the operation room an easier acceptance and a better feedback for further improvements. Some simulation results have been presented.

Stress distribution around a crack in plane micropolar elasticity. **Stanislav Potapenko** (University of Waterloo, Canada) IC/CT3965/094

The theory of micropolar elasticity (also known as Cosserat or asymmetric theory of elasticity) was introduced by Eringen to eliminate discrepancies between classical theory of elasticity and experiments in cases when effects of material microstructure were known to contribute significantly to the body's overall deformation, for example, materials with granular microstructure such as polymers or human bones. These cases are becoming increasingly important in the design and manufacture of modern day advanced materials as small-scale effects become very important in the prediction of the overall mechanical behavior of these materials.

In this presentation we use the boundary element method to find the solution for an infinite domain weakened by a crack in plane Cosserat elasticity, when stresses and couple stresses are prescribed along both sides of the crack (Neumann boundary value problem), and discuss its convergence. To illustrate the effectiveness of the method for applications we consider a crack in a human bone which is modelled under assumptions of plane micropolar elasticity. We find the numerical solution for stresses around the crack and show that the solution may be reduced to the classical one if we set all micropolar elastic constants equal to zero. We come to the conclusion that there could be up to 26 percent difference in quantitative characteristics of the stress around a crack in the micropolar case in comparison with the model when microstructure is ignored.

Analytical solution to the problem of adhesive elastic contact of a sphere with a substrate. **Olesya Zhupanska** (University of Florida, USA) IC/CT3527/015

The renewed interest in adhesive contact problems is associated with the development of advanced measurement techniques, i.e. atomic force microscopy, nanoindentation, which enable testing of mechanical properties of materials at the nanometer scale. Interpretation of some of the measurement results is a challenging problem and is still under discussion. The problem is partially attributed to adhesion of contacting surfaces that influence contact interaction between the instrument tip and tested material surface. The most widely recognized adhesive contact models, i.e. JohnsonŰKendallŰRoberts (JKR) and DerjaguinŰMullerŰToporov (DMT) take into account only the transmission of normal stress whereas contact shear stresses are neglected in the assessment of the mechanical deformation. Meanwhile, the influence of contact shear stresses on the size of the contact area and therefore the normal force-displacement relationship measured in the experiments may be quite significant.

In this work we have developed an exact solution to the problem of adhesive contact of an elastic sphere with a rigid substrate. We have preserved the influence of the shear stresses on the normal displacement in the contact zone and have not applied any additional physical simplification to the solution. Using a carefully chosen general solution in the form of Papkovich-Neuber functions, a special curvilinear coordinate system, namely toroidal coordinates, and the Meler-Fok integral transform we have derived an exact analytical solution to the formulated contact problem. A detailed analysis of the contact stresses, strain, displacement, and contact zone sizes has been performed.

The hybrid methodology to determinate state of material during tensile test. **Leszek Malag** (Koszalin University of Technology, Poland), Leon Kukielka (Koszalin University of Technology, Poland) IC/CT3104/094

The basic problems occur the engineering calculations with finite elements method (FEM) is to acceptance the suitable form of mathematical model, which describe the mechanical properties of analyzed materials as well as obtaining the constants in this model. The macroscopic material models are published in the literature, they are elaborate on the basic tensile test and compression test, which are basic tests permitting of occur the plasticity and the ultimate strength properties. To indeed the influence factor on value of stresses and strains is the shape and dimension of specimen.
The tensile test described in the ISO norm with the foundation is test, where the ultimate strength properties in the studied specimens is average value. Using these properties in numerical calculations it causes that the essential differences between results calculations and experimental measurements occurrence of qualitative and quantitative.
In this paper is propose the new methodology to defining the stresses and strains states, where the finite elements method were used. The proposed hybrid methodology to defining the states of stresses and strains in metallic specimens, were applied in one-axial tensile test. These states were evaluated with elaborated applications in program ANSYS LS-DYNA. The present application allow to obtain the stresses and strains distributions in each place of specimen and in each time duration of the tensile test process.

Ray method for solving boundary-value dynamic problems of arbitrary spatially curved rods. **Yuriy Rossikhin** (Voronezh State University, Russian Federation), Marina Shitikova (Voronezh State University, Russian Federation) IC/CT604/094

The ray method is developed for solving boundary-value dynamic problems connected with the propagation of planes of strong and weak discontinuity in spatially curved linear elastic rods of arbitrary cross-section. Equations of three-dimensional theory of elasticity are used, which at first should be written on the wave surface with the help of the theory of discontinuities in the rectangular system of coordinates, one of which is tangential to the rod's centerline and the other two are the

main central axes of the rod's cross-section, and then are integrated over the rod's cross-sectional area. It is assumed that the discontinuities in stresses on the sections with the normals perpendicular to the rod's centerline can be neglected as compared to those on the sections with the normals parallel to the centerline. Rod's cross-sections remain to be planar during its deformation. These assumptions result in the generation of two wave surfaces in the space-curved rod which propagate with the velocities of bending-longitudinal and rotational-shear waves which are equal to $\sqrt{\frac{E}{\rho}}$ and $\sqrt{\frac{\mu}{\rho}}$, respectively, where E and μ are the longitudinal and shear moduli, respectively, and ρ is the density. When solving boundary-value problems, the values to be found are represented in terms of the ray series [1], wherein coefficients are the discontinuities in partial-time derivatives of the desired functions, and the time passed after wave front arrival at an arbitrary point is the independent variable. The ray series coefficients are determined from the recurrent equations of the ray method within an accuracy of arbitrary functions, which are found then from the boundary conditions. Similar approach was applied in [2] for investigating transient waves in thin elastic plates and shells. Examples illustrating the effectiveness of the ray method during the solution of the problems of the shock interaction, resulting in propagation of transient waves of strong discontinuity in spatially curved rods are presented. This research is supported by the Russian Foundation for Basic Research under Grant No.05-08-17936.

Orthogonality of 3D time-harmonic modes in viscoelastic laminates and the method of far-field evaluation for finite acoustic sources. **Dmitry Zakharov** (Moscow State Univ. of Railway Engineering, Russian Federation) IC/CT864/094

Modes of an infinite laminate subjected to homogeneous boundary conditions on the faces are considered. For the general mode representation supporting angular symmetry the orthogonality relations are derived and expressed using the reciprocity theorem. Exact solutions of some particular boundary value problems are obtained. A method for exact calculation of the far field to an acoustic source given in the form of surface load or body force, localized in a finite region, is suggested. Some examples of practical interests are presented in context of modelling fields, radiated by ultrasonic transducers into the inspection solids.

Trapped modes in elastic waveguides. **Julia Postnova** (Imperial College London, UK), Richard Craster (Imperial College London, UK) IC/CT2434/094

Trapping of energy is a common feature of many wavebearing structures, here we will consider waveguides with slowly varying localized curvature or thickness. Trapped modes occur at particular frequencies (resonant frequencies) and are localized in an area of geometry variation. Localization of energy is often undesirable and it is important to avoid excitation of a structure at resonant frequencies. During the last few decades the existence of trapped modes in non-uniform acoustic and quantum waveguides has been extensively investigated. The purpose of this talk is to discuss the possibility of trapped modes in non-uniform elastic waveguides that have a perturbation in thickness or in curvature and to provide an appropriate theory for obtaining frequencies at which trapped modes are excited. We develop an asymptotic procedure which reduces the governing equations to a single ordinary differential equation including all the essential physics. It is shown that this reduced model has the same functional form for both guides (bent and topographically varying plates), therefore the two problems are mathematically identical. We consider waveguides subject to different types of boundary conditions (traction-free boundaries, rigid-clamped boundaries and a combination of them). For an acoustic bent plate with mixed boundary conditions the sign of the curvature function plays an important role in existence of trapping. We also consider the three-dimensional geometry of a topographically varying plate with waves propagating along the third dimension and decaying with a distance from it. A mathematical explanation and physical argument of the existence of trapped modes depending on different situations are given. Numerical results based upon the Newton-Kantorovich method are compared with the asymptotic solution and good agreement between two methods is shown.

Nonlinear vibrations for non-destructive testings, EDO models. **Bernard Rousselet** (Université de Nice Sophia Antipolis, France) IC/CT3430/094

Non linear vibrations for non destructive testings, ODE models

Recent experimental work show that it is possible to detect damages in structures by measuring non linear vibrations. The starting point lies in several publications of the russian school of physics (Sutin-Donskoy, 1998 Ekimov-Didenkulov-Kasakov in 1999, Zaitsev-Sas 1999); more recently Moussatov-Castagnede-Gusev(2002) .

This presentation focusses on the analysis of the response in the frequency domain of a vibrating structure submited to a force acting exactly at one or two frequencis: apparition of subharmonics, intermodulations between a high and low frequency.

Recently, G. Vanderborck has performed experiments with cables of bridges and has been able to detect defects by looking at the response in the frequency domain: intermodulations appear for the damaged cable.

Models of damage for monitoring cables and beams will be discussed here.

This type of approach has been presented in previous conferences by Vanderborck and the author (Colloque national de Calcul de structures, 2005,2007, SAVIAC 2005, and in meetings of french GDR 2501 ("Etude de la propagation ultrasonore en vue du controle non destructif")) .

Stability of viscoelastic systems under stochastic parametric excitation. **Vadim Potapov** (Dept. of Structural Mechanics, Moscow State Univ., Russian Federation) IC/CT526/096

The stability of viscoelastic systems, excited by parametric loads in the form of random Gaussian stationary processes with rational spectral densities, is investigated. Almost sure stability and stability with respect to statistical moments of different order is analyzed. The estimation of the stability is carried out with help of top Liapunov exponents. For the simulation of input random processes and for the solution of integro-differential equations a numerical method is offered. It is shown that positions of stability boundaries in considered cases differs principally from similar positions, if random loads have the form of Gaussian white noises.

Analytical determination of residual stresses in a butt weld of two thin rectangular plates. **Yuriy Tokovyy** (National Taiwan University), Chien-Ching Ma (National Taiwan University) IC/CT1096/096

Residual strains and stresses caused by welding, influence essential accuracy of manufacturing, durability, and other operational characteristics of welded members of structures. Computational-experimental methods are widely used for determination of residual stress-strain state. One of such methods is the method of conditional plastic strains which is based on the solving inverse problems of mechanics of deformable solids with eigen-strains under experimental information obtained by physical methods. Thus it is supposed that a material of the welded element of structure is elastic with exception of the weld zone which exhibits elastic-plastic behavior.

For solving above mentioned inverse problems, it is necessary for researcher to have a 'convenient' analytical solutions of corresponding direct problems, especially in the case of bounded bodies.

This report presents a technique of finding an exact analytical solution of a direct problem of determination of residual stresses in a rectangular plate with rectilinear butt weld. By solving this problem it is assumed, that two butt-welded plates make one rectangular (main) plate, and the welded seam is modeled as a field of residual strains locally distributed in the main plate. The edges of the main plate are free from force loadings. For construction of the solution to the direct problem, which consists in determination of stress state of the main plate under known field of residual strains, the analytical technique based upon direct integration of the equilibrium and compatibility equations in terms of stresses, proposed by Vihak, is used. Stress tensor components are found in the closed form of an explicit functional dependence on the given residual strains. It is proved that the stresses found are self-equilibrated.

The analysis of a residual stress state of rectangular plate for different ratio of length of its sides is carried out. Influence on a stress state of change of distribution character of residual strains in sites of welds near boundaries is investigated. Comparison of calculated results obtained by the proposed method with results of the known approximate methods is carried out, and also limits of application of the last ones are established.

Asymptotic behaviour of rigid plastic solutions in the vicinity of fictional interfaces and non-local fracture criteria. **Elena Lyamina** (Institute for Problems in Mechanics RAS, Russian Federation) IC/CT473/096

In the case of a rigid/perfectly plastic material model with arbitrary isotropic smooth yield criterion, the velocity fields adjacent to surfaces of maximum friction (surfaces where the friction stress is equal to the shear yield stress) must be describable by nondifferentiable functions where the maximum shear strain rate and the effective strain rate approach infinity. In particular, the equivalent strain rate follows an inverse square root law near the friction surfaces. Modifications of the material model may or may not change the singular character of the solutions in the vicinity of such surfaces. In particular, several models of pressure-dependent plasticity require singular velocity fields in the vicinity of maximum friction surfaces but the asymptotic behaviour of these fields depends on the specific model. A conceptual difficulty related to singular velocity fields appears if the model in question includes an evolution equation. Usually, in such cases solutions have no physical sense. The situation is very similar to that in linear elastic fracture mechanics where stresses are infinite at crack tips. A possible way to resolve this difficulty is to introduce non-local quantities. In the present paper, the initial/boundary value problem consisting of a planar deformation comprising the simultaneous shearing and expansion/contraction of a hollow cylindrical specimen of material is considered. This combined deformation ensures that there are no rigid regions, i.e. the material is everywhere in a state of yield. Symmetry in the circumferential direction dictates that all quantities are a function of the radial direction only. Such a statement of the problem permits rather a simple solution with no simplified assumptions. The material model includes a popular damage evolution equation. It is shown that the local damage parameter cannot be used because the solution has no physical sense. A non-local parameter is proposed to overcome this difficulty.

Conditional Lagrange derivative and its application in modeling of solids. **Peter Béda** (Budapest University of Technology and Economics, Hungary), Gyula Béda (Budapest University of Technology and Economics, Hungary) IC/CT2193/096

Constitutive equations play an essential role in most problems of the mechanics of continua. Such equations are used to take into account the physical properties of materials. There are numerous ways to derive constitutive equations, but no generally accepted one exists. The most critical situation can be found, when inelastic deformations are present. Our paper aims to show what to do in material modeling for an inelastic body. The method we use is based on the virtual work and on the variation of some function W with respect to the strain tensor

$$\int_{t_0}^{t_1}\int_V \sigma\cdot\cdot\delta\varepsilon dV dt \equiv \delta\int_{t_0}^{t_1}\int_V W dV dt.$$

Here, stress, strain and the variation of strain are denoted by σ, ε and $\delta\varepsilon$, respectively. The strain tensor is the Lagrange derivative $\$_\varepsilon$ of W with respect to ε, thus in the uniaxial case the constitutive equation is

$$\sigma\,(=\$_\varepsilon(W)) = \frac{\partial W}{\partial\varepsilon} - \frac{d}{dt}\left(\frac{\partial W}{\partial\dot\varepsilon}\right) - \frac{d}{dx}\left(\frac{\partial W}{\partial\varepsilon'}\right).$$

Generally, Lagrange derivative defines an elastic body. In the following we assume that an additonal equation $K=0$ should also be satisfied and calculate the Lagrange derivative of $F=W+\lambda K$. The first variation of F is called the conditional Lagrange derivative of function W. Then the possible constitutive equation reads

$$\sigma = \frac{\partial A}{\partial\varepsilon}+\lambda\frac{\partial K}{\partial\varepsilon}-\left(\frac{\partial D}{\partial\varepsilon}-\frac{\partial B}{\partial\sigma}+\lambda\frac{\partial^2 K}{\partial\dot\varepsilon\partial\sigma}\right)\dot\sigma-\lambda\frac{\partial^2 K}{\partial\dot\varepsilon\partial\varepsilon}\dot\varepsilon-\left(\frac{\partial E}{\partial\varepsilon}-\frac{\partial C}{\partial\sigma}\right)\sigma',$$

which may describe inelastic behavior, too. The conditions for λ are formulated by the material stability assumption, as in several cases. Here we use Lyapunov stability based concepts.

Modeling, analysis and simulation of the human femur: prosthesis of femur head. **Orlando Martín Hernández Bracamonte** (Universidad Nacional de Trujillo, Peru), José Manuel Olivencia Quiñones (Universidad Nacional de Trujillo, Peru) IC/CT872/009

We report the results obtained when carrying out the analysis of the strengths and strains that take place when prosthesis of femur head are implanted in the human femur. The modeling is made with tools provided by Computer Aided Geometry Design, using Non Uniform Rational B-Splines representations (NURBS). In the analysis of the strengths and strains, produced in the bone-cement-prosthesis interaction, partial differential equations of the coupled system are obtained for the displacements and deformations, that allow to analyze cases of physical and biological loads, under which will be work the implants during their useful life, which also is estimated; because of the frequent phenomenon of bony absorption and the consequent relaxation and loss of the replacement surgery. The obtained equations are solved by finite element method, with the corresponding estimation of the obtained errors. The simulations will be performed using high level software able to show realistic visualizations of the observed phenomena in real time. The fracture of the femur neck is a frequently observed trauma and has taken to the authors to make the present work. The obtained results will allow to make the modeling, analysis and simulation of other bony structures and the implants of the corresponding prosthesis.

Heuristic search for a predictive strain-energy function in nonlinear elasticity. **Dmitri Miroshnychenko** (University of Leicester, UK) IC/CT4003/092

In this work, we present a semi-structural and semi-phenomenological model (Miroshnychenko *et al.* J. Mech. Phys. Solids 53 (2005) 748–770) that emerged in a search for a more powerful and predictive strain-energy function in order to better account for nonlinear elastic behaviour of polymeric materials. This development had been led to by evaluation and comparison of predictive capability for three models: the eight-chain model (Arruda and Boyce J. Mech. Phys. Solids 41 (1993) 389–412), the first stretch invariant model, and the first and second stretch-invariant additive model to reproduce the mechanical behaviour of elastomeric materials in experiments using data due to Treloar (Trans. Faraday Soc. 40 (1944) 59–70).

The eight-chain model produces very similar results to those of the first stretch invariant model. Thus, it is shown that the former can not be greatly enhanced within the limitation of the latter or also, as it happens, of the first and second stretch-invariant additive model. However, significant improvement is critically needed in order to better cope with prediction of data due to Treloar (1944), especially in equibiaxial extension. The semi-structural and semi-phenomenological model that we propose retains the traits and corrects the faults of the eight-chain model, thus conforming more closely to the quintessential, classical data due to Treloar (1944). This composite model and its modification (the filament model) also suggest how a new structural model can be developed that would have only two material parameters and be able to outperfom previous models.

IC/PP3589/092: Analysis of thermal stresses in a visco-elastic tri-material under a point heat-source.

Presenter: Ching-Kong Chao (National Taiwan University)

A general solution for a thermoviscoelastic trimaterial combined with a point heat source and a point heat sink is presented in this work. Based on the method of analytic continuation associated with the alternation technique, the solutions to the heat conduction and thermoelastic problems for three dissimilar, sandwiched media are derived. A rapidly convergent series solution for both the temperature and stress field, expressed in terms of an explicit general term of the corresponding homogeneous potential, is obtained in an elegant form. The hereditary integral in conjunction with the Kelvin-Maxwell model is applied to simulate the thermoviscoelastic properties, while a thermorheologically simple material is considered. Based on the correspondence principle, the Laplace transformed thermoviscoelastic solution is directly determined from the corresponding thermoelastic one. The real time solution can then be solved numerically by taking the inverse Laplace transform. A typical example concerning the interfacial stresses generated from a combined arrangement of a heat source and sink are discussed in detail. The corresponding thin film problem is also discussed.

Keywords: thermoviscoelasticity; trimaterial; interfacial stresses; analytic continuation

IC/PP841/094: Elastoplastic problem for cylindrical shells with crossing cracks.

Presenter: Iryna Kostenko (Lviv, Ukraine)

The solution of problem of fracture for a cylindrical shell weakened by cracks with plastical areas is constructed with using the δ_k- model. The generalized δ_k- model is used to construct a mathematical model of shell, plasticity strips at the crack extension are modelled by fictitious cracks, the faces of which are under unknown normal $N$and bending moments M. These stresses and moments satisfy the corresponding plasticity conditions for shells

The crack faces do not come in contact in the process of strain. It is assumed that the crack sizes, the load value and material behaviour are such that plastical strains develop at the crack extension in the form of a thin strip throughout the shell thickness.

Centers of cracks are allocated along the guiding $\beta = 0$ (β is normalized to radius R of a middle surface of the shell coordinate along the generatrix.) It is assumed that the shell is under the conditions of cyclic symmetry and may be considered as a cylindrical panel $|\beta| \le \beta_0$ with a crack $|\alpha| \le \alpha_0, \beta = 0$ ($\alpha_= l/R, l$ is a half-length of a real crack, $\alpha_0 = l_0/R, l_0 = l_0/R, l_0-$ length of plastical area before the top of crack, α normalized to Rcoordinate along the guiding $\beta = 0, k-$ is the number of cracks).

Numerical analysis behavior of parameter $\alpha_0 = l_0/R$, when value of parameter $N_2^0/(2h\sigma_T))$ is known. Parameter $\delta_k$is obtained from such equation:

$$\delta_k = a_1 v_1 + a_N v_N + a_M v_M,$$

where a_1, a_N, a_M- known coefficients, which was founded as a solution of system of singular integral equation satisfying the corresponding plasticity conditions for shell.

IC/PP4042/094: Longitudinal waves at a micropolar fluid/solid interface.

Presenter: Dilbag Singh (Punjab University, Chandigarh, India)
Co-author: Sushil Kumar Tomar (Panjab University, Chandigarh, India)

In this paper, we have explored the possibility of propagation of plane waves in a micropolar fluid of infinite extent. The phenomena of reflection and transmission of longitudinal elastic at a plane interface between a homogeneous micropolar fluid half-space and a micropolar solid half-space has also been investigated. It is found that there exist four plane waves propagating with distinct speeds in a micropolar fluid. All the four waves are found to be dispersive and attenuated. The reflection and transmission coefficients are found be the functions of the angle of incidence, elastic properties of the half-spaces and frequency of the incident wave. Frequency equation for the Stoneley waves at micropolar solid/fluid interface has also been derived. Numerical computations have been performed for a specific model. The dispersion curves and attenuations of existed waves in micropolar fluid have been computed and depicted graphically. The variations of various reflection and transmition coefficients are are also shown against the angle of incidence. The real and imaginary parts of phase velocity of Stoneley waves have also been plotted with non-dimensional wavenumber. Results of some earlier workers have been deduced from the present formulation.

IC/PP4890/095: Particle dynamic method for solution of physical and geometrical nonlinear problems of elasticity.

Presenter: Muaed Oshkhunov (Kabardino-Balkarian State University, Russian Federation)

The discrete method of solid media into interactions particles is presented. Interaction potential between particles depends only on distance and may imitate physical and geometrical nonlinear properties of media. Classic problems of elasticity are realized as limit state with respect to time of dynamic system of particles. Various discrete models and relations of these algorithms with finite element methods are discussed. The numerical results and comparison with the classic solutions of elasticity are presented. Besides the temperature and phase confirmation are also considered.

IC/PP912/096: Variational coupled formulation of the Navier–Stokes problem in Lagrangian coordinates.

Presenter: Natalia Tuchkova (Russian Academy of Sciences, Moscow)
Co-author: Sergey Lurie (Russian Academy of Sciences, Moscow)

The variational formalism of formulation of non-holonomic media models is offered. This approach is based on the formal generalization of continued mechanics models of deformable bodies on the four-dimensional space of events with a four-dimensional vector of the generalized displacements. Time of process is included in the generalized four-dimensional system of coordinates and considered as one of independent coordinates.

As kinematic connections it is proposed to use generalized the Cauchy relations for a four-dimensional vector of the generalized displacement media: a four-dimensional vector of the generalized displacement. The general form of the constitutive equations for non-holonomic media is established. These constitutive equations are defined with the help of the non-integrability conditions for possible work of internal force factors.

The variational equation non-holonomic linear media is obtained and the appropriate initial and boundary problems are formulated. It is proved strictly, that within the framework of the offered model irreversible processes proceed with positive dissipation, and the second law of thermodynamics takes place. In result, the couple model of the dynamic thermoelasticity with dissipative properties is formulated and the appropriate initial -boundary problems is written. As a special case the combined model of creep and a relaxation is received.

The couple variational formulation of the Navier–Stokes problem in Lagrangian coordinates is obtain, allowing to formulate the consistent system of initial and boundary conditions. Within the framework of specific model the generalized equation of heat conductivity is received, the treatments of Fourier hypothesis (for heat flow) and Duamel–Neumann hypothesis are given also.

This work is supported by the Russian Foundation for Basic Research (Project 05-07-90134 and Project 06-01-00051).

IC/PP4187/096: Stochastic finite-layer method.

Presenter: Marek Wyjadlowski (Technical University Wroclaw, Poland)

The finite layer method provides the efficient method for the analysis of soil deposits which are horizontally stratified. The method can be used to analyse the settlement under two and three dimensional conditions. The settlement of horizontally layered soil deposits can be analysed by breaking the load into Fourier Components. For better accuracy, a larger number of harmonics is required for computations. Each of these Fourier components can be analysed separately and the final solution can be obtained by syntetizing the component solutions. The paper deals with the analysis of randomly inhomogeneous media as soils. In many practical cases, the soil profile can be approximated by horizontal layers which have properties varying in the horizontal directions. The paper combines the FLM and effective Stochastic techniques Monte Carlo Simulation to solve the problem of foundation settlement.

IC/PP762/015: Deformation state of flexible cylindrical shells in pre-critical region.

Presenter: Olga Tumashova (Lvivska Politechnica, Ukraine)

The problems of equilibrium of thin elastic shells in precritical region of deforming are given with the nonlinear systems of connectied differential equations. The problems of deforming thin elastic cylindrical shells with variable thickness and curvature in one direction, based on the solving two-dimentional nonlinear problem. This nonlinear problem are solved using difference approximations, linearization, a stable method of discrete orthogonalization. Consider the elastic shallow cylindrical panel $(2a * 2b)$ with variable thichness and curvature, which is under the normal surface load q. Describing nonlinear task about the strain of shallow shells under the strength influences in supposition, that curvature or thickness-variables can be written down, as the solving system of differential equa-

tions of type:

$$\begin{aligned} \frac{\partial \vec{N}}{\partial x} &= \vec{F}(x, y, \vec{N}, \frac{\partial \vec{N}}{\partial y}, \frac{\partial^2 \vec{N}}{\partial y^2}, \frac{\partial^3 \vec{N}}{\partial y^3}, \frac{\partial^4 \vec{N}}{\partial y^4}, q) \\ B_1 \vec{N} &= \vec{b}_1\,, \quad x = \pm a \\ B_2 \vec{N} &= \vec{b}_2\,, \quad y = \pm b \quad , \end{aligned}$$

where $\vec{N} = \{N_x, N_{xy}, Q_x, M_x, u, v, w, \vartheta_x\}$.

This nonlinear problem is solved using the methods: difference approximations, linearization and discrete orthogonalization. Consided the deformation of the elastic shallow cylindrical panel with variable thickness and curvature is under the influence of normal surface load q.

10: Fluid Mechanics, Minisymposia

IC/MP290/010: **Multiphysics and multiscale methods in hydrodynamics.**

Organiser: Luca Bonaventura (Politecnico di Milano, Italy)
Co-organiser: Fausto Saleri (Politecnico di Milano, Italy)
Co-organiser: Edie Miglio (Politecnico di Milano, Italy)

The simulation of complex hydrodynamics phenomena involves the presence of different space and time scales and different physical phenomena. In order to resolve all the time and space scales a full 3D Navier–Stokes system should be solved; in practice this is too expensive from the computational point of view hence the use of some reduced (low-dimensional or simplified) models is advisible. The adoption of these simplified models in all the domain can cause a low level of accuracy in the solution so a suitable coupling between the full model and the reduced ones is required. The same idea can be used in order to (partially) include 3D effects into 2D models (or 2D effects into 1D models). Moreover, even from the physical point of view, some effects due to complex phenomena occuring in water flow (e.g. sedimentation) can be simulated by means of suitable reduced model.

The aim of the minisymposium is to collect contributions emphasizing the usefulness of multiscale and multiphysics methods in order to efficiently solve the above mentioned problems.

An iterative procedure to solve a coupled athmosphere-ocean turbulence model. **Tomás Chacón Rebollo** (Universidad de Sevilla, Spain), Stephane Del Pino (Commissariat à l'Energie atomique, France), Driss Yakoubi (Université Pierre et Marie Curie, France) IC/MT1568/010

In this contribution we focus our attention on the modelling of the surface layer between the athmosphere and the ocean. We are interested in designing effective procedures to solve the following coupled model:

$$\begin{aligned} -\nabla\cdot(\alpha_i(k_i)\nabla\mathbf{u}_i)+\nabla p_i &= \mathbf{f}_i && \text{in } \Omega_i,\\ \nabla\cdot\mathbf{u}_i &= 0 && \text{in } \Omega_i,\\ -\nabla\cdot(\gamma_i(k_i)\nabla k_i) &= \alpha_i(k_i)|\nabla\mathbf{u}_i|^2 && \text{in } \Omega_i,\\ \mathbf{u}_i &= 0 && \text{on } \Gamma_i,\\ k_i &= 0 && \text{on } \Gamma_i,\\ \alpha_i(k_i)\partial_{\mathbf{n}_i}\mathbf{u}_i - p_i\mathbf{n}_i + c_i(\mathbf{u}_i-\mathbf{u}_j)|\mathbf{u}_i-\mathbf{u}_j| &= 0 && \text{on } \Gamma,\\ k_i &= \lambda|\mathbf{u}_1-\mathbf{u}_2|^2 && \text{on } \Gamma, \end{aligned} \tag{1}$$

where Ω_i is a bounded domain of $\mathbb{R}^d$, of boundary $\partial\Omega_i = \Gamma_i \cup \Gamma$, $\Gamma = \partial\Omega_1 \cap \partial\Omega_2$ being the interface between the two fluids. Γ is assumed to be flat. Each of the two turbulent fluids is modelled by a simplified one-equation turbulence model whose unknowns are the velocity $\mathbf{u}_i$ and the turbulent kinetic energy (TKE) k_i. In the first equation we model the generation of eddy viscosity. The quantity $\alpha_i(k_i)$ is the turbulent viscosity. The fluids are assumed to be incompressible (second equation). In the third equation we model the generation of TKE by means of a production source term, and also the turbulent dissipation of TKE: the function $\gamma_i(k_i)$ is also a turbulent diffusion. We assume non-slipping boundary conditions in the boundary parts Γ_i for simplicity (fourth and fifth equations). The sixth equation globally models the interaction of the two boundary layers on one and another side of the interface Γ as friction effects, by means of a set of boundary conditions similar to Manning's law. Finally, the last equation models the generation of TKE in the interface. The coefficients c_i and λ are positive. We assume that the turbulent diffusions α_i, γ_i belong to $W^{1,\infty}(\mathbb{R})$ and verify that $\alpha_i \geq \nu$ and $\gamma \geq \nu$, for some $\nu > 0$. The eddy diffusions usually are unbounded functions, but this renders the analysis extremely hard, so we consider a simplified model, that still includes several realistic non-linear interactions.

This system was studied[1] where existence and uniqueness of small smooth solutions were proved. Spectral and Finite Element discretizations were studied in subsequent papers by the same authors and co-workers. In these papers, the ability of these discretization techniques to approach the solutions of model (1) was proved. However, in both cases the discretizations achieved consisted in fully non-linear sets of algebraic equations.

Our purpose here is to derive iterative procedures to solve our system that decouple the interactions of the problem, leading mainly to linear problems.

Iterative procedure. Let us introduce the function space $\mathbf{X}_i = \{\mathbf{v} \in \mathbf{H}^1(\Omega_i)^d;\ \mathbf{v} = 0 \text{ on } \Gamma_i\}$. Consider also two conjugate positive real numbers r and r' such that $r > d$. We introduce the following iterative procedure to solve the coupled system:

find $(\mathbf{u}_i^{n+1}, p_i^{n+1}, k_i^{n+1}) \in \mathbf{X}_i \times L^2(\Omega_i) \times W^{1,r'}(\Omega_i)$, such that $\forall \mathbf{v}_i \in \mathbf{X}_i$:

$$(\alpha_i(k_i^n)\nabla\mathbf{u}_i^{n+1}, \nabla\mathbf{v}_i)_{\Omega_i} - (\nabla\cdot\mathbf{v}_i, p_i^{n+1}) + c_i(|\mathbf{u}_i^{n+1}-\mathbf{u}_j^{n+1}|(\mathbf{u}_i^{n+1}-\mathbf{u}_j^{n+1}), \mathbf{v}_i)_\Gamma = (\mathbf{f}_i, \mathbf{v}$$

and $\forall q_i \in L^2(\Omega_i)$ we require that $(\nabla\cdot u_i^{n+1}, q_i) = 0$, with $k_i^{n+1} = 0$ on Γ_i, $k_i^{n+1} = \lambda|\mathbf{u}_1^{n+1} - \mathbf{u}_2^{n+1}|^2$ on Γ, such that

$$\forall \phi_i \in W_0^{1,r}(\Omega_i),\ (\gamma_i(k_i^n)\nabla k_i^{n+1}, \nabla\phi_i)_{\Omega_i} = (\alpha_i(k_i^n)|\nabla\mathbf{u}_i^{n+1}|^2, \phi_i)_{\Omega_i}. \tag{2}$$

Observe that the problem for the $\mathbf{u}_i^{n+1}$ (first equation in (.1)) is in reality non-linear due to the presence of the Manning-like source term. This is a mild non-linearity due to the monotonic nature of this term, that may be made explicit in practice if mass-lumping techniques are used.

Our main result states that if the sequences $(\mathbf{u}_i^n)_n$ and (k_i^n) are bounded in $W^{1,3+\epsilon}(\Omega_i)^d$ and $W^{1,3}(\Omega_i)$, then, for small enough data (in a convenient sense), the iterative scheme (.1)–(2) is contracting. This proves in addition the uniqueness of solutions of the coupled model.

We shall present some numerical tests realized with the software FreeFEM3D (see [2]) in meaningful situations, that agree with the expectations of this result.

Assimilation of images for river hydraulic simulations. **Jérôme Monnier** (Université Grenoble I, France), Xijun Lai (Chinese Academy of Sciences), Marc Honnorat (Université Grenoble I, France), Francois-Xavier Ledimet (INRIA Rhône-Alpes, France) IC/MT2664/010

A major difficulty in the numerical simulation of river hydraulic flows is bound to model parameters definition. Variational data assimilation makes it possible to combine the model and observation data in order to identify the value of model parameters consistent with reality. However, in river hydraulics, observation data are available only in very small quantities. Water level measurements can be available at gauging stations, but it is the main channel only and they are very sparse in space. Velocity measurements are even rarer and uncertain, since they require complex human interventions. Consequently, in practice these observations are usually not sufficient to take full advantage of data assimilation for identification purposes. This lack of data is all the more problematic in case of extreme events such as floods. Thus, remote sensing data such as video and spatial images offer a large potential which is not fully exploited yet. In this talk, we address the assimilation (in

addition to classical data)of the following two types of images : 1) video images of particles flowing at surface; 2) satellite images of the flood plain. In case 1), this led us to extend the method to extra lagrangian data. The trajectory of particles advected by the flow bring information on the surface velocity using an extra transport model. In case 2), we defined an appropriate cost function and adopted a temporal strategy into the variational data assimilation process. These methods are implemented into our software DassFlow. The direct code is a HLLC Riemann solver for 2D shallow-water equations. The cost functions are minimized using a Quasi-Newton algorithm, which implies the computation of its gradient using an adjoint model. The latter is created with the help of the automatic differentiation tool Tapenade. Numerical twin data assimilation experiments demonstrate that these approaches makes it possible to improve the identification of model parameters. If considering real flows, difficulties arising from the shallow-water model incompleteness are pointed out. **References** 1. "Lagrangian data assimilation for river hydraulics simulations" M. Adaption of hierarchical multiscale hydrodynamical models. **Daniela Capatina-Papaghiuc** (Université de Pau et des Pays de l'Adour, France), Mohamed Amara (Université de Pau et des Pays de l'Adour, France), David Trujillo (Université de Pau et des Pays de l'Adour, France) IC/MT1912/010

We are interested in the hydrodynamical modeling and numerical simulation of an estuarian river flow. Since the use of a realistic 3D model would engender a huge computational cost, our goal is to implement different lower-dimensional models on adequated regions of the river and then to automatically couple them. Several 2D and 1D hydrodynamical models of shallow water type exist in the literature, but their mathematical justification is rather heuristic. We employ here some new hydrodynamical models, derived in a unified manner in a variational framework. For this purpose, we put the physical time-discretized 3D problem, based on the Navier-Stokes equations and satisfying natural boundary conditions, under a nonlinear mixed weak form and then we obtain the simpler models by a projection method. This approach avoids any closure problem that one usually encounters in the shallow water system and moreover, all the models provide a 3D velocity and pressure.

The key point is that we thus get hierarchical models : the 1D problem is a conforming approximation of the 2D horizontal, respectively vertical models, which are both conforming approximations of the 3D one. This hierarchy allows a natural coupling, in the sense that the transmission conditions between the different models are implicitly contained in the formulations. The coupling is then achieved through residual *a posteriori* error indicators. One can note that a different coupling strategy, also based on *a posteriori* model estimators using the dual-weighted residual method, was developed by Braack and Ern and applied to the shallow water system by Perotto.

In this talk, we briefly describe the derived models, their mathematical analysis and the comparison with the classical shallow water equations and then we focus on the model adaption. We define the model indicator between the 3D model and a generic lower-dimensional approximation and we prove its reliability. For this purpose, we adapt a result of Brezzi, Rappaz and Raviart established for finite dimensional approximations of nonlinear problems to our multiscale approximation at the continuous level. Finally, the discretization of the previous models will be discussed and numerical tests will be presented, illustrating the implementation of the adaptive coupling between the 1D and any of the two 2D models.

IC/MP290/010: Multiphysics and multiscale methods in hydrodynamics. #2

Organiser: Luca Bonaventura (Politecnico di Milano, Italy)

Co-organiser: Edie Miglio (Politecnico di Milano, Italy)

(For abstract, see session #1 above.)

A section-averaged model for mobile-bed river hydraulics. **Alberto Deponti** (Università degli Studi di Torino, Italy), Luca Bonaventura (Politecnico di Milano, Italy), Edie Miglio (Politecnico di Milano, Italy), Giorgio Rosatti (Università degli Studi di Torino, Italy) IC/MT1411/010

A section-averaged model for mobile-bed river hydraulics is presented and analysed. The model is based on the conservation equations of liquid mass, solid sediment mass and momentum. By using appropriate closure formulae for sediment transport and for bottom friction, a system of three non-linear hyperbolic equations is obtained. In particular, for the sediment transport process, empirical closure formulae are used; these impose a highly non-linear relation between sediment and liquid discharges. The equations are averaged over the channel cross-section in order to account for irregular geometries. By using appropriate averaging coefficients, the model is capable to account for two-dimensional phenomena such as non–uniformities in velocity distribution and sediment transport across the section, non-uniformities in bottom friction and in morphological modification along the wet contour.

Analysis of the system eigenstructure shows the importance of considering arbitrary cross-sections for properly describing hydraulic flows and morphological modifications of the cross-section induced by sediment transport process. The analysis also shows that these two physical processes are strongly coupled throughout a wide region of flow regimes around unitary Froude number; particularly, the width of this region is strongly affected by cross-section geometry and by the sediment transport regime. For these reasons, a coupled numerical model is implemented. The model imposes the conservation of total mass (liquid and solid) and computes hydraulic flows and morphological modifications of the cross-section at the same time. Applications to idealised benchmarks and realistic test cases will be presented and discussed.

High-order upwind scheme for modelling turbulent shallow water flow in hydraulic structures. **M. Elena Vazquez-Cendon** (Universidade de Santiago de Compostela, Spain), Luis Cea (Universidade da Coruña, Spain) IC/MT2419/010

An unstructured finite volume model for quasi-2D free surface flow with wet-dry fronts and turbulence modelling is presented.

The convective flux is discretised with either a an hybrid second-order/first-order scheme, or a fully second order scheme, both of them upwind Godunov's schemes based on Roe's average. The hybrid scheme uses a second order discretisation for the two unit discharge components, whilst keeping a first order discretisation for the water depth. In such a way the numerical diffusion is much reduced, without a significant reduction on the numerical stability of the scheme, obtaining in such a way accurate and stable results. It is important to keep the numerical diffusion to a minimum level without

loss of numerical stability, specially when modelling turbulent flows, because the numerical diffusion may interfere with the real turbulent diffusion.

In order to avoid spurious oscillations of the free surface when the bathymetry is irregular, an upwind discretisation of the bed slope source term [1] with second order corrections is used. In this way a fully second order scheme which gives an exact balance between convective flux and bed slope in the hydrostatic case is obtained.

The $k-\varepsilon$ equations are solved with either an hybrid or a second order scheme [3].

The results given by a first order scheme, the hybrid scheme and the fully second order scheme are compared in several free surface shallow flows. A first order scheme may give rather good predictions for the water depth [3], but it introduces too much numerical diffusion and therefore, it excessively smooths the velocity profiles. This is specially important when comparing different turbulence models, since the numerical diffusion introduced by a first order upwind scheme may be of the same order of magnitude as the turbulent diffusion. In all the numerical simulations the importance of using a second order upwind spatial discretisation has been checked.

A Roe-type scheme for two-phase gravitational granular flows with bottom topography. **Marica Pelanti** (École Normale Supérieure de Paris, France) IC/MT2411/010

We study a depth-averaged model of gravity-driven mixtures of solid grains and fluid flowing over non-flat basal surface. In particular, we are interested in applications to geophysical flows such as avalanches and debris flows, which typically involve both solid material and interstitial fluid.

The model system consists of mass conservation and momentum balance equations for the solid and fluid components, and it can be shown to be hyperbolic at least when the difference of phase velocities is sufficiently small.

Difficulties in the numerical approximation of the model equations arise from the presence of non-conservative products that involve the derivatives of the unknowns and that couple together the sets of equations of the two phases. Here we numerically solve the model system by a high-resolution finite volume scheme based on a Roe-type Riemann solver. Several numerical tests are presented and discussed. In particular, we show that numerical results of the two-phase model with indefinitely large interphase drag agree with the exact solution of the reduced model that can be derived theoretically by assuming that drag is strong enough to drive instantaneously phase velocities to equilibrium.

Work done in collaboration with François Bouchut (ENS Paris) and Anne Mangeney (IPGP).

IC/MP21/033: Theoretical aspects of 3D water waves.

Organiser: Gérard Iooss (Université de Nice Sophia Antipolis, France)
Co-organiser: Mark Groves (Loughborough University, UK)

The theory of two-dimensional water waves has seen a vigorous renewal of interest in the last fifteen years, a development fuelled by the emergence of powerful new mathematical methods such as spatial dynamics and variational techniques. The study of three-dimensional water waves has additional mathematical difficulties, in particular due to the presence of a two-dimensional free surface (with or without surface tension), the impossibility of using complex-variable techniques (which are well adapted to two-dimensional potential flows), and the occurence of a richer set of inherent symmetries. However, three-dimensional waves are certainly the more interesting variety from a physical point of view. The last five years have witnessed significant progress in this area, including results at a mathematical level (concerning periodic or spatially localised waves), at a numerical level (new fundamental simulations of large amplitude waves), and at an experimental level (involving experiments designed to explain observations and inspire theoreticians). This minisymposium presents an interdisciplinary spectrum of researchers working on three-dimensional water waves and focuses upon mathematical results on the Euler equations (with a free surface or interface) and studies of model equations.

On solitary water-wave interactions. **Walter Craig** (McMaster University, Canada) IC/MT3429/033

Existence and stability of fully-localised 3D gravity-capillary solitary water-waves. **Mark Groves** (Loughborough University, UK) IC/MT3557/033

A solitary wave of the type advertised in the title is a critical point of the Hamiltonian, which is given in dimensionless coordinates by

$$H(\eta,\xi)=\int_{\mathbb{R}^2}\left\{\frac{1}{2}\xi G(\eta)\xi+\frac{1}{2}\eta^2+\beta\sqrt{1+\eta_x^2+\eta_z^2}-\beta\right\},$$

subject to the constraint that the impulse

$$I(\eta,\xi)=\int_{\mathbb{R}^2}\eta_x\xi$$

is fixed. Here $\eta(x,z)$ is the free-surface elevation, ξ is the trace of the velocity potential on the free surface, $G(\eta)$ is a Dirichlet-Neumann operator and $\beta>1/3$ is the Bond number.

In this talk I show that there exists a minimiser of H subject to the constraint $I=2\mu$, where $0<\mu\ll 1$. The existence of a solitary wave is thus assured, and since H and I are both conserved quantities its stability follows by a standard argument. 'Stability' must however be understood in a qualified sense due to the lack of a global well-posedness theory for three-dimensional water waves.

Non-symmetric three-dimensional gravity water waves: part I. **Gérard Iooss** (Université de Nice Sophia Antipolis, France), Pavel Plotnikov (Lavrentyev Institute of Hydrodynamics, Russian Federation) IC/MT5015/010

We consider travelling water waves in a potential flow on an infinitely deep fluid layer, which form a bi-periodic horizontal pattern on the free surface, in absence of surface tension. The pattern is not of diamond type, the two basic wave vectors K_1 and K_2 having different lengths. The waves may be considered as the nonlinear superposition of two plane waves, with corresponding wave numbers K_1 and K_2, and amplitudes ε_1 and ε_2, provided that at the bifurcation, K_1, K_2 and the bifurcation parameters μ (built with a wave length, the acceleration of gravity and the velocity of the waves) and the direction of propagation $\mathbf{u}_0$, satisfy the dispersion relation.

We first show how to build the asymptotic expansion of bifurcating 3-dimensional waves defined up to a horizontal shift, as a power series of the amplitudes $\varepsilon_1, \varepsilon_2$, the direction of propagation being close to $\mathbf{u}_0$. All coefficients may be computed explicitely in terms of the two angles made by K_1 and K_2 with $\mathbf{u}_0$. Due to the *occurence of small divisors*, the main difficulty for proving the existence of solutions, possessing the above asymptotic expansions, is the inversion of the linearized operator at a non trivial point, for applying the Nash–Moser theorem. This operator is the sum of a second order differentiation along a certain vector field (having a *non zero rotation number*), and an integro-differential operator of first order, both depending periodically of coordinates.

The idea of the method follows [1] and [2], with the additional difficulty due to the above non-zero rotation number. This talk shows *how to proceed formally* to this inversion provided two irrationality conditions on the parameters are realized. The precise conditions are provided in the next talk by P. Plotnikov.

Non-symmetric three-dimensional gravity water waves: part II. **Pavel Plotnikov** (Lavrentyev Institute of Hydrodynamics, Russian Federation), Gérard Iooss (Université de Nice Sophia Antipolis, France) IC/MTR/

We consider periodic waves at the surface of an infinitely-deep perfect fluid, only subjected to gravity g and resulting from the nonlinear interaction of two symmetric travelling waves with the wave vectors K_1, K_2 and magnitudes ε_i. We deal with non-resonance case when the dispersion equation has the only basic symmetric solution in the lattice of periods. Our goal is to prove of existence of solutions to the nonlinear problem bifurcating from the trivial solution close to the asymptotic solutions constructed in the lecture by G. Iooss. The essential difficulty here is that we assume the absence of surface tension, which leads to a so-called *small divisor problem*. As it was shown in the previous lecture by G. Iooss that the linearised operator at a non-trivial point can be reduced, by the change of independent variables , to a canonical pseudodifferntial operator with constant coefficients in the principal part. The peculiarity of our problem is that the small divisors form clusters in the lattice of periods. We employ a modification of the Weyl theory on uniform distributions of irrational numbers modulo 1 to deduce the effective estimates of small divisors and to prove the invertibility of the principle part of the canonical operator. The most substantial ingredient of our approach is the descent method which allows to reduce the canonical pseudodifferential equation on the 2-dimensional torus to a Fredholm type equation (see[1,2]). Finally we exploit the Nash–Moser implicit function theorem and prove the existence of bifurcating doubly-periodic symmetric waves for any value of the parameters ε_i in a product of one-dimensional Cantor sets dense at 0.

Gravity-capillary lumps and related problems. **Triantaphyllos Akylas** (MIT, USA) IC/MT583/033

Fully localized three-dimensional solitary waves, commonly referred to as *lumps*, have received far less attention than two-dimensional solitary waves in dispersive wave systems. Most studies have considered the long-wave limit where lumps are described by the Kadomtsev–Petviashvili (KP) equation. In the water-wave problem, in particular, lumps of the KP type are possible only in the strong-surface-tension regime, a condition that limits the water depth to a few millimetres.

We report on a new class of lumps that is possible under less restrictive physical conditions. Rather than long waves, these lumps bifurcate from linear sinusoidal waves of finite wavenumber at an extremum of the phase speed. As the group and phase velocities are equal there, small-amplitude lumps resemble fully localized wavepackets with envelope and crests moving at the same speed, and the wave envelope along with the induced mean-flow component are governed by a coupled Davey–Stewartson equation system of elliptic-elliptic type. The lump profiles feature algebraically decaying tails at infinity owing to this mean flow.

In the case of water waves, lumps of the wavepacket type are possible when both gravity and surface tension are present on water of finite or infinite depth. Moreover, a linear stability analysis of gravity-capillary solitary waves, that also bifurcate at the minimum phase speed, reveals they are unstable to transverse perturbations, suggesting a mechanism for the generation of lumps.

This generation mechanism is further explored in the context of the two-dimensional Benjamin (2-DB) equation, a generalization to two spatial dimensions of the model equation derived by T.B. Benjamin for uni-directional small-amplitude long interfacial waves in a two-fluid system with strong interfacial tension.

Dynamics of solitary gravity-capillary waves. **Paul Milewski** (University of Wisconsin, Madison, USA) IC/MT3467/033

In contrast with gravity waves, where localized, solitary waves exist only in two dimensions and only in shallow water, localized capillary–gravity waves exist in any depth and in both two and three dimensions. In three dimensions these waves were recently found, numerically, in a variety of models and in the full Euler equations ([Milewski], [Yang and Akylas], [Parau, Vanden-Broeck and Cooker]) and proven to exist analytically ([Groves and Sun]).

Little, however, is known about their dynamics. Although some aspects of these waves may be described using Nonlinear Schrödinger type equations, these equations do not seem to capture important features of the waves and their dynam-

ics. We discuss these differences and propose model equations in two and three dimensions which capture more closely the features and dynamics of the waves as compared to full Euler calculations in two-dimensions. The unidirectional model equation, in two dimensions, takes the form

$$R_t + i\mathcal{H}R = \mathcal{N}(R)\,, \tag{1}$$

where $\mathcal{N}$ is a quadratic nonlinear term and where the linear operator has the full deep-water capillary-gravity Fourier symbol

$$\widehat{\mathcal{H}} = sign(k)\sqrt{|k|(1+k^2)}\,. \tag{2}$$

We also discuss briefly the forced problem where waves are generated by a moving pressure force, simulating some aspects of wind-wave generation.

This is joint work with Benjamin Akers.

Long internal-wave models. **Jean-Claude Saut** (Université Paris-Sud, France) IC/MT3460/033

We present a systematic derivation of long waves models for internal waves together with a rigorous justification. This is a work in collaboration with Jerry Bona, Thierry Colin and David Lannes.

Justification of 3D asymptotics for water-waves. **David Lannes** (Université de Bordeaux, France) IC/MT4125/010

The water-waves equations admit many kinds of asymptotic regimes, depending on the physical characteristics of the flow: shallow/deep water, large/small amplitude, long/short waves, isotropic/anisotropic, bottom variations, etc. Such asymptotic models include: KP equation, 2DH Boussinesq, Shallow-water, Green-Naghdi, Serre equations, etc.

A systematic way to derive all the corresponding asymptotic models will be described. In order to rigorously justify them (i.e., in order to prove that their solutions converge to the exact solution of the full water-waves equations), a general well-posedness theorem for the water-waves equations will be proved. A crucial point is the boundedness of a particular energy, uniformly with respect to all the physical parameters.

IC/MP967/100: Complex flows: theoretical and computational aspects.

Organiser: Nils Svanstedt (Chalmers University of Technology, Sweden)

The minisymposium will view theoretical modeling of complex flows in porous media, in fluid/structure interaction and in heterogeneous fluids. Various tools for upscaling will be presented. The symposium will also view recent development in computational aspects of complex flows. Various multiscale finite element approaches will be presented.

Adaptive variational multiscale methods: a general framework. **Axel Målqvist** (UC San Diego, USA), Michael Holst (University of California, San Diego, USA), Mats Larson (Umeå University, Sweden) IC/MT1278/100

We present a framework for construction and error analysis of adaptive variational multiscale methods. We use a systematic technique for approximating the impact of the fine scale part of the solution on the coarse scale part of the solution. The fine scale is approximated by a sum of solutions to decoupled localized problems, which are solved numerically on a fine grid partition of a patch of coarse grid elements. The sizes of the patches of elements may be increased to control the error caused by localization. We derive error estimates in the energy norm which captures the dependency of the crucial discretization parameters: the coarse grid mesh size, the fine grid mesh size, and the sizes of the patches. Based on the error estimates we present an adaptive algorithms that automatically tunes these critical parameters.

Homogenization of gas–water flow processes in porous media. **Insa Neuweiler** (Universität Stuttgart, Germany) IC/MT2220/100

Modeling of water balances in partly saturated heterogeneous porous media often requires upscaled flow models. Such upscaled models can be derived using homogenization theory. They are based on a scale expansion and are therefore valid for specific flow regimes. Upscaled models and their effective parameters will be discussed for gravity dominated and for capillary dominated flow.

The effective parameters of the upscaled models depend on the structure of the heterogeneous parameter field. If the detailed structure is unknown, estimates have to be found, which are based on a simple characterization of the heterogeneity. Usually heterogeneous structure is characterized by second order statistical moments of the parameter fields (i.e. variance and correlation function). However, only multi-Gaussian fields are sufficiently characterized by these parameters. Stochastic properties of natural soil are mostly far from multi-Gaussian. If fields are not multi-Gaussian, other measures such as connectivity of certain materials could be better suited to characterize heterogeneous structures. The influence of connected paths of different parameter values will be demonstrated and different methods to quantify connected structures will be discussed.

Differential effective medium theory is a method to estimate the effective parameters, where information about measures for the connected structures can be taken into account. It will be demonstrated, that such methods yield better predictions than second order theory methods, if fields have connected extreme values. Except for the effective model parameters, connected parameter structures have an influence of the trapping of fluid during the flow process, which may lead to irregular fluid distributions or an unstable displacement front. The influence of trapping will also be discussed in the talk.

The work was done in collaboration with Hartmut Eichel and Hans-Jörg Vogel.

Multiscale mixed/mimetic FEM on complex geometries. **Stein Krogstad** (SINTEF ICT, Norway), Jørg Aarnes (SINTEF, Norway), Knut-Andreas Lie (SINTEF ICT, Norway) IC/MT2295/100

We consider a multiscale mixed finite element method (MsMFEM) for the modelling of porous media flow on models with complex geometrical features. The MsMFEM formulation is based on a hierarchical grid approach, where subscale effects are taken into account through the use of basis functions which are numerical solutions of local subscale/subgrid flow problems. By using these basis functions to discretize the global flow equations on a coarse grid, one can retain the efficiency of an upscaling method, while at the same time produce detailed and conservative velocity fields with subgrid resolution.

In reservoir simulation, the subgrid is typically given by a geomodel represented in a corner-point grid format, which is the industry standard for modelling complex reservoir geometry. As a result, the subgrid may be highly irregular. Thus, to apply the MsMFEM to such models, there are mainly two challenges. First, one needs a stable and conservative subgrid-solver for the local flow problems, and second, one needs means of choosing suitable coarse grids.

In this talk, we focus on the second challenge, coarse gridding for MsMFEM on models with complex geometrical features. One of the main advantages of the MsMFEM formulation is in the great flexibility with respect to grids. In fact, the coarse grid can in principle be any partition of the subgrid, where each coarse block is a connected collection of subgrid cells. However, we argue that in the process of generating coarse grids, one should follow certain simple guidelines to improve overall accuracy. Based on these guidelines, we discuss processing techniques aiming towards a fully automated gridding procedure. The presented methodology will be illustrated through numerical examples.

Stochastic homogenization of convection–diffusion problems. **Nils Svanstedt** (Chalmers University of Technology, Sweden) IC/MT2892/100

We study the asymptotic behaviour for a class of convection–diffusion problems where both the convection field and the diffusion process are random. By using G-convergence for monotone operators we obtain a homogenized problem where the homogenized operator is chaeacterized explicitly. Wee also show some numerical simulations.

IC/MP3867/101: Experimental and numerical aspects of 3D water waves.

Organiser: Gérard Iooss (Université de Nice Sophia Antipolis, France)
Co-organiser: Mark Groves (Loughborough University, UK)

The theory of two-dimensional water waves has seen a vigorous renewal of interest in the last fifteen years, a development fuelled by the emergence of powerful new mathematical methods such as spatial dynamics and variational techniques. The study of three-dimensional water waves has additional mathematical difficulties, in particular due to the presence of a two-dimensional free surface (with or without surface tension), the impossibility of using complex-variable techniques (which are well adapted to two-dimensional potential flows), and the occurence of a richer set of inherent symmetries. However, three-dimensional waves are certainly the more interesting variety from a physical point of view. The last five years have witnessed significant progress in this area, including results at a mathematical level (concerning periodic or spatially localised waves), at a numerical level (new fundamental simulations of large amplitude waves), and at an experimental level (involving experiments designed to explain observations and inspire theoreticians). This minisymposium presents an interdisciplinary spectrum of researchers working on three-dimensional water waves and focuses upon numerical simulations and experiments.

Experimental investigation and modeling of deep-water patterns of surface waves. **Diane Henderson** (Pennsylvania State University, USA) IC/MT3569/101

We present experiments in which we generate patterns of deep-water surface waves and investigate the geometric properties and the stability of these patterns. Craig & Nicholls (2002) found solutions to the fully nonlinear inviscid water wave equations whose periodic cell structure is rectangular. Iooss & Plotnikov (2006) found solutions for the same equations in different parameter regimes in which the periodic cell structure is hexagonal. We try to find these solutions in the experiments. We examine the stability of the patterns in the experiments and in asymptotic models, including the nonlinear Schrödinger (NLS) equation and a vector form of the NLS equation. In the inviscid models, the patterns are unstable to modulational perturbations. But we find that any amount of damping, of the right type, no matter how small, stabilizes this well-known instability both in the model equations and in the experiments. The NLS and VNLS equations, modified for damping, do a good job of predicting the evolution of the wave patterns with perturbations added. This work is joint with Harvey Segur, Joe Hammack, John Carter, Matt Patterson and others.

Computation of 3D interfacial waves and related flows. **Emilian Părău** (University of East Anglia, UK) IC/MT4066/101

Numerical computations of three-dimensional gravity and gravity–capillary interfacial waves are presented. Solutions of the fully nonlinear equations are calculated by boundary-integral equation methods. A configuration consisting of two superposed fluids bounded above by a free-surface is also considered. Further results are presented for time dependent free surface flows.

Numerical computations of 3D gravity-capillary waves. **Jean-Marc Vanden-Broeck** (University of East Anglia, UK) IC/MT1996/101

Three dimensional gravity capillary waves are considered. Accurate numerical computations are presented for the full Euler equations. The numerical methods are based on boundary integral equation techniques. Numerical evidence of three dimensional solitary waves is presented. The waves have decaying oscillations in the direction of propagation and monotonic decay in the direction perpendicular to the direction of propagation. Further results are presented for interfacial waves and time dependent free surface flows.

Numerical stability of a KdV equation with a negative forcing. **Sungim Whang** (National Institute for Mathematical Sciences, Republic of Korea), Jeongwhan Choi (Korea University, Republic of Korea) IC/MT2028/101

The waves at the free surface waves of a incompressible and invisid fluid in a two dimensional domains with horizontal rigid flat bottom with a small obstruction are considered. A time dependent KdV equation with a negative forcing is derived and studied both theoretically and numerically. The existence of a negative solitary-wave-like solution of the equation near the Froude number is proved and the numerical stability of the solution is also studied. The numerical stability of the positive both symmetric and unsymmetric solitary-wave-like solutions are also studied.

IC/MP64/103: Vortex dynamics.

Organiser: Hassan Aref (Danmarks Tekniske Universitet, Denmark)
Co-organiser: Paul Newton (University of Southern California, USA)

In 1858 Helmholtz published his seminal paper "Über Integrale der hydrodynamischen Gleichungen, welche den Wirbelbewegungen entsprechen", (J. reine u. angew. Math. **55**, 25–55), wherein he established his three laws of vortex motion in much the same way one finds them in any advanced textbook today. P. G. Tait later published an English translation, "On integrals of the hydrodynamical equations which express vortex motion", (*Phil. Mag.* **33**, (1867) pp.485–512). For the next century or so vortex dynamics matured as a subfield of fluid mechanics, always commanding at least a major chapter in treatises on the subject; e.g., Lamb's *Hydrodynamics* (1932) or Batchelor's *Introduction to Fluid Dynamics* (1967). In due course entire treatises were devoted to vortex motion; e.g., Poincaré's *Théorie des Tourbillons* (1893), Villat's *Lecons sur la Théorie des Tourbillons* (1930), Truesdell's *The Kinematics of Vorticity* (1954), and Saffman's *Vortex Dynamics* (1992). The range of applicability of Helmholtz's work grew to atmospheric and oceanographic flows, to all branches of engineering and applied science, aerodynamics in particular, and ultimately, to superfluids, including these days Bose–Einstein condensates. Today, one can scarcely imagine an investigation in fluid mechanics that does not invoke the role of vorticity or vortices in some way. Nevertheless, while vortices and vortex motion are ubiquitous, vortex dynamics retains a characteristic *flavor* deriving from its Lagrangian interpretation and from its frequently intuitive, *mechanistic* description of flow phenomena. At the same time vortex dynamics has consistently demanded rather sophisticated mathematical tools, in part because of the counterpoint between Lagrangian and Eulerian aspects that the field constantly demands. The minisymposium will bring leading experts in vortex dynamics to ICIAM and stimulate discussion across a broad range of mathematical fluid dynamics.

150 years of vortex dynamics. **Hassan Aref** (Danmarks Tekniske Universitet, Denmark) IC/MT1356/103

We are approaching the sesquicentennial of Helmholtz's seminal paper of 1858 in which the study of vortex motion was launched. In this lecture I will give a description of the laws of vortex motion. I will describe some of the models of vortices that have been studied and the wealth of phenomena that have been addressed using the theory of vortex motion. These include the totally erroneous notion of Kelvin that atoms are a kind of vortex motion in the ether, an idea that led to huge amounts of high quality work even though the application turned out to be misguided. Experiments by the American physicist Mayer on pattern formation by floating magnets were seized upon by Kelvin and his followers as illustrating the periodic table of the elements. Later, in 1911-12, T. von Kármán provided a remarkable application of the vortex dynamics of Helmholtz in his explanation of the structure and stability of bluff body wakes, an application that has stood the test of time. Some 35 years after that, through work by Onsager and Feynman, it was realized that superfluids could nucleate and sustain vortices that obeyed Helmholtz's dynamical equations. In 1979 the first experiments visualizing vortex arrays in rotating superfluid ^{4}He were reported. Understanding the geometry of the patterns formed by the vortices has been of ongoing interest. Recently, similar patterns have been observed in Bose-Einstein Condensates (BEC). Several highlights of the rich and sometimes bizarre history of vortex dynamics will be presented, with appropriate recognition of the topics to be presented by other authors in the minisymposium.

Self-similar collapse of the straight vortex-filament dodecapole. **Yoshi Kimura** (Nagoya University, Japan) IC/MT2711/103

The vortex dodecapole, the superposition of three equal-strength, orthogonal, vortex quadrupoles, was proposed by Rich Pelz and his co-workers as a candidate initial condition for a finite-time singularity in ideal hydrodynamics. In this paper, we examine the simplest model of the vortex dodecapole in which the vortex tubes are replaced with straight vortex filaments of infinitesimal thickness. It is demonstrated that this model permits a self-similar collaps solution which provides the time dependence of $\sqrt{t - t_c}$ where t_c, the collapse time, depends on the initial configulation. This time dependence agrees with the one observed in the direct numerical (pseudo spectral) simulations of the vortex dodecapole.

(This work is a part of collaboration with Rich Pelz who passed away suddenly in 2002.)

Point-vortex models of bluff body wakes. **Mark Stremler** (Virginia Tech, USA) IC/MT3080/103

When a two-dimensional bluff body wake is modeled as two oppositely-signed point vortices in a singly periodic strip, any choice of vortex positions gives a uniformly translating relative equilibrium. In the case of the staggered Kármán street, the wake translates along its length, and adjacent co-moving points (i.e., stagnation points in a frame moving with the vortices) are joined by streamlines. For small deviations from this ideal case, however, the wake translates obliquely, and the streamline structure becomes more intricate. Fluid entrained in the wake can be wrapped around many of the vortices before passing through to the other side. I will discuss the bifurcations that occur in the streamline topology of obliquely translating vortex streets and the influence of this structure on mixing in wakes.

The Kármán vortex street appears consistently in the wakes of rigid bluff bodies. If the body is instead free (or forced) to oscillate, the resulting wake structure can be much more exotic, with three or more vortices shed per period. I will present relative equilibrium configurations of singly periodic point vortex systems as models of these exotic wakes. When three vortices are shed per period, the possible configurations can be determined systematically. The focus here will be on those configurations that translate along the wake. The streamline topology in various exotic wake models will also be discussed.

Asymmetric equilibria via Brownian ratchets. **Paul Newton** (University of Southern California, USA) IC/MT1351/103

We formulate the problem of finding N-vortex equilibria in terms of the linear algebra problem $A\vec{\Gamma} = 0$, where A is an MxN configuration matrix whose entries are made up of inter-vortical distances, and $\vec{\Gamma} \in R^N$ is the vector of vortex strengths. In order for an equilibrium to exist, A must be rank-deficient, and the dimension of the nullspace corresponds to the number of free parameters available in choosing the vortex strengths. We randomly place N points in the plane, perform a singular value decomposition on A, and use the smallest singular value as a 'ratchet'. At each step, we allow the points to execute a random walk, and retain the new configuration only if the smallest singular value is reduced. This way, we can drive the configuration to an equilibrium (at least one singular value is zero) corresponding to an A matrix with any desired rank. The Frobenius norm allows us to measure the size of the equilibrium and distances between equilibria. We will also comment on uses of the pseudospectrum of A to understand the robustness of the configuration.

IC/MP234/103: **General solutions of fluid dynamics.**

Organiser: Victor Miroshnikov (College of Mount Saint Vincent, USA)

General solutions of fluid dynamics create a necessary mathematical framework for solving numerous boundary-value problems and bring understanding of general properties of fluid flows away from boundaries. The general solutions also build up a positive approach to the millennium problem on the existence of smooth solutions of the Navier–Stokes equations by constructing explicit solutions in the form of the Boussinesq–Rayleigh series, which provide a straightforward relation between formulations of unsteady problems in various dimensions. This minisymposium focuses on new developments in analytical, symbolic, and numeric algorithms for computing the general solutions of the Navier–Stokes, Stokes, and Oseen equations, considers applications of the general solutions for creeping flows, Poiseuille flows, and flows away from boundaries, and also addresses possible generalizations of the general solutions.

General solutions of the Navier–Stokes equations in various dimensions. **Victor Miroshnikov** (College of Mount Saint Vincent, USA) IC/MT2781/103

General solutions of the unsteady Navier-Stokes equations in one, two, and three dimensions are derived symbolically as the Boussinesq-Rayleigh series in a coordinate and continued numerically by parallel computing. The main results of this presentation are sorted in three groups. First, several exact theorems are proved for the Navier-Stokes equations and the Stokes equations since the differential and tensor recurrent relations may be written in the closed form. For instance, it is shown that flows away from boundaries may be decomposed into the following basic flows: the Couette flow, the Poiseuille flow, the Bernoulli flow and the Stokes flow. Second, symbolic existence theorems are obtained since computation, validation, and convergence of the free and forced general solutions of the Navier-Stokes equations is treated symbolically. Third, new numerical algorithms of evaluation, continuation, and visualization of multi-scale flow structures are developed. In three dimensions, the nested vortex pairs of the Poiseuille flow are visualized by stream surfaces and stream tubes formed by streamlines with constant integration times, which continue two-dimensional isocurves of the streamfunction. Comparison of mixing by the Poiseuille flow in one, two, and three dimensions is given through simulated animations, which display connections between flows in various dimensions.

General solutions of the Stokes equations and their applications. **Tirumalasetty Amaranath** (University of Hyderabad, India) IC/MT2617/103

The Stokes[1] equations have been one of the most extensively studied equations ever since Stokes discussed the resistance experienced by a slowly moving sphere. These equations have prompted mathematicians to develop a rich mathematical theory of slow, viscous flows which have benefited both scientists and engineers alike. There are numerous sphere theorems and solutions in literature which provide simple formulae for calculating physical quantities like drag and torque experienced by a sphere starting from Lamb's[2] solution till a recent solution of Stokes equations due to Palaniappan *et al.*[3]. We review the applications of the solution due to Palaniappan *et al.*[3], which we showed is a complete general solution, for the problem of an arbitrary Stokes flow past a sphere under different boundary conditions. The earliest formula for drag and torque acting on a sphere in an unbounded arbitrary Stokes flow was given by Faxen[4]. Such formulae have also been derived using the solution proposed in[3]. We also discuss another complete general solution of Stokes equations proposed by us, which is suitable for discussing the problem of an arbitrary Stokes flow involving plane boundaries. Payne and Pell[5] derived a formula for drag on an arbitrary body in an axisymmetric flow. An analogous result was obtained by Lawrence and Weinbaum[6] who calculated the force on an arbitrary axisymmetric body in an oscillatory motion. Although some methods have been derived earlier to develop exact solutions for axisymmetric bodies of different shapes, there seems to be no general method, albeit approximate, which gives the solution for the problem of non-axisymmetric Stokes flow for arbitrary shaped bodies, even for the simple case of an ellipsoid. A numerical method has been suggested by us to solve the problem of an arbitrary Stokes flow past a body of arbitrary shape.

General solutions of the Oseen equations. **B. Sri Padmavati** (University of Hyderabad, India) IC/MT2620/103

Flows at low Reynolds numbers are governed by the Stokes[1] equations. However these equations do not provide a satisfactory explanation of Stokes paradox; i.e., in explaining the validity of these equations at sufficiently large distances from the boundary. Oseen[2] modified Stokes equations by including a linearized convective term to them to explain it. These equations are known as Oseen equations. Lamb[3] proposed solutions of both Stokes and Oseen[2] equations. However Lamb's solution of Oseen equations which is commonly used is not adequate to represent all solutions of Oseen equations.

We shall discuss some results pertaining to divergence free vector fields which are relevant to Oseen equations and present a solution of Oseen equations. We also discuss some other previously known solutions of Oseen equations. We explain the merits of the new solution and highlight its advantages. We further show that it is a general solution, in the sense that, every other solution of Oseen equations can be represented in the form given by this new solution.

Explicit description of isotropic tensor of high rank using polyadics for microhydrodynamics. **Teruo Kumagai** (Tokyo University of Science, Japan) IC/MT34/010

The purpose of this paper is to describe explicitly the isotropic tensor of high rank in three-dimensional space using the polyadic algebra for the recent continuum mechanics such as microhydrodynamics. The derivation of the Navier–Stokes equation for viscous flows needs an explicit description of a relation between strain and stress under the assumption of slight deformations and isotropic properties of the fluids. The strain–stress relation has already been derived using the isotropic ten-

sor of the rank up to 4. However there are left rooms to derive the isotropic tensor of the higher rank than 4. In this paper the isotropic tensor of the high rank is derived using the polyadic algebra. The polyadic, the direct product of unit vectors, denotes merely a combination of unit vectors, but is effective to represent the tensor for the transformation of coordinates. The isotropic property of fluids means the invariable property of the tensor for the rotation of the coordinates. The polyadic expression represents the tensor of rank n as the summation of combinations of unit vectors. For example n=0,1,2,3 and 4 means a scalar,a vector,a dyadic,a triadic and a tetradic respectively. The isotropic tensor of the high rank with even number is concluded to be described explicitly as the summation of combinations of the Kronecker delta, while the isotropic tensor of the high rank with odd number is concluded to be described as the summation of both of the Kronecker delta and the Edington epsilon. For example the isotropic tensor of rank 4 is described explicitly as the summation of three kinds of products of the Krönecker delta. This equation leads directly to the Navier–Stokes equation and the basic equtaion for microhydrodynamics.

IC/MP224/103: Mathematical analysis of the Euler equations and its applications.

Organiser: Hisashi Okamoto (Kyoto University, Japan)

The Euler equations are the governing equations of incompressible inviscid fluid motion. Mathematical results on the Euler equations are fewer than those of the Navier–Stokes equations. However, they are sources of many interesting phenomena such as vortex filaments, vortex sheets, and possible singularities. From a mathematical viewpoint these are far from well-understood, despite intensive numerical simulations. The present mini-symposium summarizes the current status of the mathematical study on the Euler equations and related equations.

On the Lagrangian dynamics for the 3D incompressible Euler equations. **Dongho Chae** (Sungkyunkwan University, Republic of Korea) IC/MT1504/103

In this talk we discuss the dynamical behaviors along the particle trajectories for some quantities of the 3D inviscid incompressible fluids. We construct ordinary differential equations satisfied by scalar quantities composed of spectrum of the deformation tensor, the hessian of the pressure and the direction field of the vorticity, and discuss the dichotomy between the finite time singularity and the long time behaviors of the various scalar quantities.

A personal survey on similarity solutions of Euler's equations. **Hisashi Okamoto** (Kyoto University, Japan) IC/MT2094/103

In this talk, I will survey some exact solutions of Euler's equations of inviscid incompressible fluid. They are obtained as solutions to some equations which are simpler than Euler equations. Those simplified equations include the Proudman-Johnson equation, equations for axisymmetric flows, and that for von Kármán's swirling flows. Since the velocity field of those solutions do not decay at infinity, their properties may not have a direct physical implication. But, if used locally in space region, they reveals interesting features and are helpful to understanding real flow phenomena. In this sense, reviewing a current status would not be uninteresting to application oriented scientist as well as mathematicians. I will begin with the issue of existence/non-existence of blow-up solutions, and then I will give some remarks concerning the role of the convection and stretching terms. It will be revealed that the convection terms prevent the solutions from blowing up. I then show some numerical experiments, from which conjectures are derived.

Blow-up and regularity problems of hypoviscous fluid equations. **Koji Ohkitani** (The University of Sheffield, UK) IC/MT2198/103

In this work, we treat generalised incompressible fluid equations with modified dissipativity. We consider specifically modifications of 1D Burgers and 3D Navier-Stokes equations, where the Newtonian viscosity is replaced with hypoviscous term $-\nu(-\triangle)^{\alpha}$, $(0 < \alpha < 1)$. The latter equations read with standard notations

$$\frac{\partial \boldsymbol{u}}{\partial t} + (\boldsymbol{u}\cdot\nabla)\boldsymbol{u} = -\nabla p - \nu_{\alpha}(-\triangle)^{\alpha}\boldsymbol{u},$$
$$\nabla\cdot\boldsymbol{u} = 0.$$

After reviewing some previous works on the subject, we will be particularly interested in the case $\alpha = 1/2$, which lies just between the Euler and Navier-Stokes equations.

In one space dimension, we will show that the Burgers equation with $\alpha = 1/2$ will generally lead to blow up in finite time. In three dimensions, we will consider under what conditions the solutions to hypoviscous equations remain smooth and decay in time.

Analytical behavior of an incompressible flow in a porous media. **Diego Cordoba** (Consejo Superior de Investigaciones Científicas, Spain) IC/MT2199/103

Here we study the analytical structure of a mass balance equation in a porous medium. Detailed mathematical criteria are developed as diagnostics for self-consistent numerical calculations indicating non-formation of singularities.

IC/MP4402/105: Recent advances in vortex dynamics: applications.

Scalar transport and conditional averaging in an annular swirling jet. **Jochen Fröhlich** (Universität Karlsruhe, Germany), Manuel García-Villalba (Universität Karlsruhe, Germany), Wolfgang Rodi (Universität Karlsruhe, Germany) IC/MT4117/107

The paper presents large eddy simulations of co-annular swirling jets into an open domain at practical Reynolds number. In each of the jets a passive scalar is introduced and its transport is computed. If the exit of the pilot jet is retracted strong coherent flow structures are generated. Average and instantaneous fields are discussed. They are compared with corresponding experimental data and very good agreement is found. Probability density functions of the scalar concentration and turbulent fluxes are determined to assess the mixing efficiency of the flow. A conditional averaging technique is devised and applied to velocity and scalars. These data show the strong impact of the coherent structures on the mixing process.

Vortical flow in thermo-acoustic devices. **Katsuya Ishii** (Nagoya University, Japan), Masahiro Ishigaki (Nagoya University, Japan), Shizuko Adachi (RIKEN, Japan), Kazuto Kuzuu (Nagoya University, Japan), Masahiro Ishigaki (Nagoya University, Japan) IC/MT4128/107

The thermo-acoustic spontaneous oscillation phenomenon plays an important role in a thermo-acoustic engine. This oscillation occurs in a long tube with large thermal gradient. The phenomena in a 2D closed long tube are investigated by the numerical calculation of the compressible Navier-Stokes equations, in which the center part of the tube wall is cold(T=Tc) and the side parts of tube wall and both end walls are hot(T=Th). While any oscillations are not observed when the temperature ratio(Th/Tc) is smaller than 7, we observe a spontaneous oscillation when the temperature ratio(Th/Tc) is larger than 9.1. In this oscillation, the center of tube is an antinode of velocity and the ends of a tube are nodes. The wide boundary layer is observed and the time averaged values of pressure and temperature are constant in the hot part of tube. On the other hand, the boundary layer is narrow and the averaged values of pressure and temperature are different in the cross section. We also observe vortical flow and additional pressure flucutuation in the cold part of tube. We analyze the oscillation mechanism in detail and discuss the relationship of the oscillation phenomenon and vortex motion in the cold part of the tube.

Aircraft-wake vortices: prediction and mitigation. **Frank Holzäpfel** (DLR Oberpfaffenhofen, Germany), Thomas Gerz (DLR Oberpfaffenhofen, Germany) IC/MT4358/107

As an unavoidable consequence of lift, aircraft generate a pair of counter-rotating vortices, the so-called wake vortices. These vortices may exert a serious danger on following aircraft if the separation between leading and following aircraft is not sufficient. The incentive of today's wake vortex research still rests on the empirically motivated separation standards between consecutive aircraft introduced in the 1970s. These aircraft separations fix the capacity of congested airports in a rapidly growing aeronautical environment.

Two approaches are addressed that aim at increasing airport capacity without compromising safety. One approach is to directly impact wake vortex strength and stability by constructive measures at the aircraft wings. For example, suitable secondary wake vortex pairs are generated by differential flap settings that may trigger instrumental vortex instabilities. On the other hand, the dominant influence of meteorological parameters like turbulence, wind shear, and temperature stratification on wake vortex fate is utilized. The physical mechanisms that control the interaction of wake vortices with their environment in the meantime are largely understood. This knowledge constitutes the basis for predicting wake vortex behavior along the glide slope and dynamically adjusting vortex separations.

The current talk will present large eddy simulations that are employed within both approaches, the developped real-time wake vortex prediction model (P2P) and the Wake Vortex Prediction and Monitoring System (WSVBS) which has demonstrated its functionality at Frankfurt airport during winter 06/07.

Vortex-wake mitigation of an airfoil with winglets by active rudders. **Robert Schöll** (RWTH Aachen, Germany), Ralf Hörnschemeyer (RWTH Aachen, Germany), Sebastian Kauertz (Airbus Deutschland GmbH, Germany), Rolf Henke (RWTH Aachen, Germany) IC/MT4387/107

Wake vortices pose a hazard to airplanes and limit the capacity of airports. The wake vortex hazard has been a subject of research for over 30 years, yet the physical processes determining vortex decay are not fully understood. In the present investigation, experiments with a rectangular planform wing are conducted with the goal of influencing and mitigating the vortex wake by the generation of additional vortices. The experiments are carried out in a water towing tank, where two-component particle image velocimetry is used as the measurement method. This setup allows the measurement of the wake up to 40 wing spans downstream of the model.

The model is equipped with ailerons and winglet-integrated rudders, which can be set up to create a system of multiple trailing vortices. By setting appropriate deflection angles, an inherently unstable vortex system can be created, which breaks down considerably faster than the system produced by a clean wing configuration. Through stability analysis, frequencies can be identified at which short wave instabilites develop. The rudders integrated in the winglets are then oscillated at those frequencies with the aim of fostering short wave instabilities, leading to accelerated decay of the vortex system. After a modification of the model, it is possible to oscillate the ailerons as well.

Preliminary results show that the wake is influenced much more effectively when both ailerons and winglet rudder are oscillated, as compared to the case with rudder oscillation only.

IC/MP129/106: Mathematics and computations of complex flows.

Organiser: Traian Iliescu (Virginia Tech, USA)
Co-organiser: Anastasios Liakos (United States Naval Academy)

Complex flow phenomena occur in many areas of the sciences and engineering. In turn, they give rise to many interesting themes of fluid dynamics such as high Reynolds-number flow and large-eddy simulation for Newtonian fluids and high Weissenberg-number flow for viscoelastic fluids. Applications of these areas include, amongst many others, energy consumption optimization and global climate change estimation, polymer-processing operations (extrusion, injection molding), and sustained plasma confinement for controlled thermonuclear fusion and liquid-metal cooling of nuclear reactors respectively.

This minisymposium will focus on the modeling, analysis, and simulation of phenomena occurring in the flow of the aforementioned fluids and on underlying questions of numerical analysis and computational issues. Thus, it will be of interest to a broad audience of applied mathematicians, numerical analysts, and computational scientists.

Advances in MHD flow simulation. **Amnon Meir** (Auburn University, USA), Paul Schmidt (Auburn University, USA), Kang Jin (Auburn University, USA) IC/MT188/106

Magnetohydrodynamics (MHD) is the theory of the macroscopic interaction of electrically conducting fluids with a magnetic field. It is of importance in connection with many engineering problems such as plasma confinement, liquid-metal cooling of nuclear reactors, the CZ crystal growth process, and electromagnetic casting.

In the viscous incompressible case, MHD flow is governed by the Navier-Stokes equations and the pre-Maxwell equations giving rise to challenging problems of mathematical analysis and numerical approximation. We will discuss recent advances in MHD flow simulation.

Mathematical issues concerning the Boussinesq approximation for thermally coupled viscous flows. **Paul Schmidt** (Auburn University, USA), Jesus Ildefonso Diaz (Universidad Complutense de Madrid, Spain), Jean-Michel Rakotoson (Université de Poitiers, France) IC/MT289/106

The flow of a viscous, heat-conducting fluid under the force of gravity is governed by a system of balance equations for momentum, mass, and energy. In the so-called Boussinesq approximation, this system reduces to the Navier–Stokes equations for an incompressible fluid, coupled to a semilinear heat equation; the main coupling terms are buoyancy and viscous heating. Frequently, the latter is negligible, in which case the resulting initial-boundary value problems are well posed in the same sense as for the classical Navier–Stokes equations without thermal coupling. However, in situations where viscous heating cannot be neglected, well-posedness is an open question. We analyze the ensuing mathematical issues and present preliminary results for a simplified model.

Mathematical modelling and numerical simulations in blood rheology. **Adelia Sequeira** (Universidade Técnica de Lisboa, Portugal) IC/MT4360/106

Blood is a multi-component mixture with complex rheologic characteristics which interacts both mechanically and chemically with vessel walls, giving rise to complex fluid-structure interaction models whose mathematical analysis is still incomplete and which are difficult to simulate numerically in an efficient manner. Experimental investigations over many years show that blood flow exhibits non-Newtonian behaviour such as shear-thinning, viscoelasticity, thixotropy and yield stress and its rheology is influenced by numerous factors including plasma viscosity, rate of shear, hematocrit, level of erythrocytes aggregation and deformability. Hemodynamic analysis of blood flow in vascular beds and prosthetic devices requires the rheological behaviour of blood to be characterized through appropriate constitutive equations relating the stress to deformation and rate of deformation.

In this talk we present a short overview of some constitutive models that can mathematically characterize the rheology of blood and some numerical simulations to illustrate its phenomenological behaviour. Using a mesoscopic lattice Boltzmann flow solver for non-Newtonian shear thinning fluids, we present a recent three-dimensional numerical study of the dynamics of leukocytes rolling and recruitment by the endothelial wall, based on in vivo experimental measurements in Wistar rat venules. Preliminary numerical results obtained for a comprehensive model of blood coagulation and clot formation, that integrates physiologic, rheologic and biochemical factors will also be presented. The corresponding three-dimensional simulations were obtained for a shear-thinning blood model using a finite volume semi-discretization in space and a three-stage Runge-Kutta time integration method.

On finite-element variational multi-scale methods for incompressible turbulent flows. **Volker John** (Universität des Saarlandes, Germany), Adela Kindl (Universität des Saarlandes, Germany) IC/MT3486/106

Variational Multiscale (VMS) Methods are a new approach for the simulation of turbulent flows. Their key feature consists in the application of a turbulence model only to so–called resolved small scales which are defined by appropriate projections. This is in contrast to the classical Large Eddy Simulation (LES) where the turbulence model is applied to all resolved scales and the resolved scales are defined by spatial averaging.

The parameters of a VMS method are the turbulence model and the spaces for the large scales and the resolved small scales.

There are several ways for the realization of a VMS method in the context of finite element discretizations. The talk gives an overview on Finite Element VMS methods and numerical examples will be presented to compare the different approaches.

IC/MP129/106: Mathematics and computations of complex flows. #2

(For abstract, see session #1 above.)

Finite-element method for viscoelastic fluid flows. **D Sandri** (Université Lyon 1, France) IC/MT2806/106

In this minisymposium we discuss the finite element (FE) method for the approximation of viscoelastic fluid flows. We consider the approximation of fluid flows obeying the Oldroyd model and particularly we study the purely viscoelastic case, the so-called Maxwell model, important in practice.
For the numerical approximation of the Maxwell model we study two kinds of methods : a method using a technique of splitting and usual FE methods based on finite element spaces satisfying inf-sup conditions relating tensor and velocity.

We also present numerical results for these methods and we discuss their stability.

Simulation of flow-induced microstructure development in liquid-crystal polymeric materials. **Christopher Cox** (Clemson University, USA) IC/MT3694/106

Liquid crystal polymers are found in commercial applications (e.g., Dupont Kevlar) and natural materials (e.g., spider silk). There is wide-spread interest in gaining deeper understanding of the flow properties of these fascinating and complex materials.
The goal of this effort is to simulate flows of liquid-crystalline polymer materials using tensor-order constitutive equations formulated by Rey and coworkers. Of particular interest is the development of textural effects and their influence on stress growth. The system of nonlinear partial differential equations governing the variation of (scalar, vector, and 2nd-order tensor) dependent variables will be described. Then the finite element formulation for this system will be discussed. Solutions under various flow conditions will be presented, beginning with simple test cases. Some comparisons to experimental results will also be provided.

This talk summarizes work conducted jointly by Professors Amod Ogale and Barr von Oehsen at Clemson University and Alejandro Rey at McGill University, Clemson University graduate students Edward Duffy and Santanu Kundu, and the speaker.

This work is supported primarily by the ERC program of the National Science Foundation under Award Number EEC-9731680.

Breaking complexity in fluid-structure interaction problems. **Georges-Henri Cottet** (Université Grenoble I, France) IC/MT3979/106

The main challenge in fluid-structure interaction problems comes form the necessity to combine models that are inherently different. A typical example is the dynamic of a living cell, which combines flow models inside the cell, elastic properties on the membrane and biochemical processes on the membrane and inside the cell.

From the numerical point of view, a common approach is to associate finite element-element type models for the fluid part with Lagrangian description of the elastic media. However these solutions are hard to implement, especially for 3D dynamics, and time-consuming. An alternative approach is to embed the whole system in a single Eulerian approach for which finite-difference algorithms are very cheap including for 3D complex behaviors. The fluid/structure interface is implicitly captured with a level-set method. Elastic properties are also formulated in terms of level-set functions. We will describe this approach and show some ongoing work in our group concerning applications in biomechanics, engineering and graphics animation.

Grid-filter models for large-eddy simulation. **Roland Bouffanais** (École Polytechnique Fédérale de Lausanne, Switzerland), Michel Deville (École Polytechnique Fédérale de Lausanne, Switzerland) IC/MT4014/106

A new interpretation of approximate deconvolution models (ADM) when used with implicit filtering as a way to approximate the projective grid filter is presented. Consequently, a new category of subgrid models, the grid filter models (GFM) is defined. ADM appear as a particular case of GFM since only approximate deconvolution is achieved. GFM can be either used with the standard filtered Navier–Stokes equations or with the formulation commonly used with ADM. The latter formulation requires an additional assumption leading to an incomplete modeling of the subgrid scales.

Based on GFM and ADM using these two different formulations of the filtered Navier–Stokes equations, several large-eddy simulations of the flow in a lid-driven cubical cavity have been carried out using the spectral element method. Numerical results for Reynolds number Re $= 12\ 000$ are presented and compared with direct numerical simulation (DNS) results found in the literature. In addition, An under-resolved DNS has also been carried-out to prove that the under-resolution is effective.

It is proved that the deconvoluted formulation, usually used with ADM, leads to an under-dissipative character of the subgrid model and explains the need of additional dissipative terms. Conversely, when using the standard filtered formulation, no additional term is needed which is of great relevance considering the confined nature of the flow and the high-order numerical method used. These results show an improvement over standard ADM-based subgrid models for large-eddy simulation.

Work done in collaboration with M.A. Habisreutinger.

IC/MP3638/106: Complex flows: mathematics and computations.

Organiser: Traian Iliescu (Virginia Tech, USA)
Co-organiser: Anastasios Liakos (United States Naval Academy)

Complex flow phenomena occur in many areas of the sciences and engineering. In turn, they give rise to many interesting themes of fluid dynamics such as high-Reynolds number flow and large eddy simulation for Newtonian fluids and high Weissenberg number flow for viscoelastic fluids. Applications of these areas include, amongst many others, energy consumption optimization and global climate change estimation, polymer-processing operations (extrusion, injection molding), and sustained plasma confinement for controlled thermonuclear fusion and liquid-metal cooling of nuclear reactors respectively.

viscoelastic fluids. Optimality and uncertainty in CFD: what is the best simulation ?. **Pierre Sagaut** (Université Pierre et Marie Curie-Paris 6, d'Alembe, France) IC/MT195/106

Numerical simulation of complex flows is at the very heart of many theoretical and industrial problems. Here, the notion of flow complexity is associated to its sensitivity/dependency with respect to large number of physical and numerical parameters. Typical physical parameters are the non-dimensional numbers such as the Reynolds number, geometrical parameters (e.g., a solid body shape), but also all parts of the physical model such as parameters that appear in turbulence models. Numerical parameters are the initial condition and the numerical errors, etc.

In almost all cases of real engineering relevance, many physical parameters are not precisely known, some of them being totally unknown. The validity of turbulence models is also not fully mastered in such configurations. In addition, the influence of the numerical errors on the solution, and their nonlinear couplings with the physical models is not fully understood.

Therefore, CFD for complex configurations is still an art, since its requires a lot of heuristics and *know how*. The present talk will present some results obtained by the author and many collaborators dealing with the quantification of flow sensitivity with respect to numerical and physical uncertainties, and the search for an *optimal* computational setup. A key tool for this is the parametrization of the space of the solution spanned by the physical model and the numerical method. The sensitivity of the solution is then defined as the local Jacobian of the solution in this space. The response surface approach is used for that purpose, based on both the Kriging and the Polynomial Chaos methods. It will be shown that, in some case, the *true* solution (as obtained from wind tunnel experiments or Direct Numerical Simulation) does not belong to the space of possible solutions. The use of a surface response approach makes it possible to define the *best* or *optimal* solution, once a measure of the error, defined as some kind of distance between the computed and the reference solutions, has been defined. It will be shown that (as can be expected), different definitions of the error yield different *best* solutions. An interesting observation is that the error is a non-convex function which exhibits several local minima in most cases, rendering the search for the *best* computational domain a difficult task. In some practical cases, such as the flow around a 2D wing, it will be shown that heuristic values of the parameters of the turbulence model and the artificial viscosities in the Jameson scheme are observed to correspond to a local minimum of the error.

Another interesting output of the surface response approach, which does not rely on any linearization approximation, is that

it allows for the description of the space of possible solutions of the computational model through statistical indicators, such as pdf and exact error bars.

A two-level Smagorinsky model. **Traian Iliescu** (Virginia Tech, USA) IC/MT187/106

A two-level method for discretizing the Smagorinsky model for the numerical simulation of turbulent flows is proposed and analyzed. The two-level algorithm consists of solving a small nonlinear system of equations on the coarse mesh, and then using that solution to solve a larger linear system on the fine mesh. We demonstrate numerically that for an appropriate choice of grids, the two-level algorithm is significantly more efficient than the standard one-level algorithm.

Recent advances in the discretization of flows with shear-dependent viscosities. **Luigi Berselli** (Università di Pisa, Italy) IC/MT240/106

We consider non-newtonian flows with shear dependent viscosity, having in mind the classical Smagorinsky model but also more general flows capable of shear thinning/thickening. We prove some estimates for the space-time discretization showing optimal convergence for the time discrete problem.

IC/MP426/001: Fast solvers for saddle-point problems with applications in fluid dynamics.

Organiser: Guido Kanschat (Texas A&M University, USA)
Co-organiser: Maxim Olshanskii (Moscow State University, Russian Federation)

We review the state of the art of the development and analysis of efficient solution methods for saddle-point problems occurring in incompressible flow computations.

Several solution methods for Stokes and Navier–Stokes equations have been developed over the last decades. During the last years some convergence to block-preconditioning of the saddle-point problems could be observed. This type of preconditioners seems to offer the greatest flexibility with respect to the actual flow model (low/high Reynolds number, stationary/instationary, non-/Newtonian) and has been studied in a considerable amount of publications. The speakers of this minisymposium have been involved in these developments and in the application of this approach to various discretizations of flow problems. We will discuss the state achieved in analysis and application of these methods as well as future trends.

Symmetric indefinite preconditioners for saddle-point problems with applications to PDE-constrained optimization problems. **Walter Zulehner** (Universität Linz, Austria), Joachim Schöberl (RWTH Aachen, Germany) IC/MT2275/106

We consider large scale sparse linear systems in saddle-point form. A natural property of such indefinite 2-by-2 block systems is the positivity of the (1,1) block on the kernel of the (2,1) block. Many solution methods, however, require that the positivity of the (1,1) block is satisfied everywhere. To enforce the positivity everywhere, an augmented Lagrangian approach is usually chosen. However, the adjustment of the involved parameters is a critical issue. We will present a different approach that is not based on such an explicit augmentation technique. For the considered class of symmetric and indefinite preconditioners, assumptions are presented that lead to symmetric and positive definite problems with respect to a particular scalar product. Therefore, conjugate gradient acceleration can be used.

An important class of applications are optimal control problems. It is typical for such problems that the cost functional contains an extra regularization parameter. For control problems with elliptic state equations and distributed control a special indefinite preconditioner for the discretized problem is constructed which leads to convergence rates of the preconditioned conjugate gradient method that are not only independent of the mesh size but also independent of the regularization parameter. Numerical experiments are presented for illustrating the theoretical results.

Performance of saddle-point preconditioners in two practical settings. **Howard Elman** (University of Maryland, USA) IC/MT5023/106

Discretization of the incompressible Navier–Stokes equations and solution of the nonlinear algebraic equations by Newton or Picard iteration requires the solution of systems of equations with saddle point structure. We give an overview of preconditioning methods for these problems, and we demonstrate the effectiveness of the methods in several practical settings. In particular, we have integrated them into a general purpose finite element package, MPSalsa, developed at Sandia National Laboratories, and we show that they are very efficient for solving models of enclosed flow and flows over obstacles in two and three dimensions. We demonstrate the effective implementation of the ideas in a large-scale parallel setting, using multigrid for component problems. Moreover, we show improvements in performance (with speedups of factors of five to ten for large problems) achieved in comparison to more traditional methods used for incompressible flow, including the SIMPLE algorithm and domain decomposition strategies. Finally, we show that these methods can be used effectively to solve incompressible flow problems that arise in a model used to construct microfluidics devices for measuring the properties of mixing fluids.

Fast solvers for viscoelastic flows. **Daniel Loghin** (University of Birmingham, UK) IC/MT2768/106

Numerical simulations of viscoelastic flow problems require the solution of large, typically sparse, systems of equations which inherit the (highly) nonlinear coupling of the original PDE model. Recent approaches, such as the elastic viscous split stress (EVSS) methods, while allowing more flexibility and the treatment of complex rheological models come at the cost of increased problem size. At the same time, there is an evident lack of efficient solution techniques. In this work we introduce and analyze a class of implicit iterative solvers based on a Schur complement approach. The technique is based on identifying a suitable decoupling of the original system of PDE through an approximation to a Schur complement operator. We illustrate our approach on discretizations of EVSS formulations of Oldroyd-type fluid models.

Augmented Lagrangian approach for saddle-point problems with indefinite $(1,1)$-block. **Maxim Olshanskii** (Moscow State University, Russian Federation) IC/MT545/106

We discuss block preconditioners for a system of linear algebraic equations of saddle-point type having indefinite and not necessarily symmetric (1,1) block. The approach is based on considering an augmented system and a special multilevel method as an inner solver for a preconditioned Krylov subspace method. To explain convergence properties of the method we first prove bounds on the eigenvalues of the augmented (1,1) block. Next we consider the application of the method to solve a problem arising in the linear instability analysis for the Navier-Stokes equations. Several new results are proved for the Schur complement of the linearized Navier-Stokes equations. This provides further insight into the convergence properties of the approach.

Saddle-point preconditioners for higher-order discontinuous Galerkin discretizations of flow problems. **Guido Kanschat** (Texas A&M University, USA) IC/MT460/106

Non-symmetric H-matrix preconditioners for the Navier–Stokes equations. **Sabine Le Borne** (Tennessee Technological University, USA) IC/MT1039/106

The ability to solve large, sparse saddle point systems arising from the Navier–Stokes equations is critical to the success of numerical fluid flow simulations. Linear systems are typically solved by iterative methods, and their convergence can be accelerated by use of suitable preconditioners. A variety of preconditioning methods for saddle point problems has been significantly extended within the last decade. Several of these preconditioners are formulated in a general framework and require the solution of subproblems which, if solved exactly, imply the solution of dense linear systems of equations. A prominent example for such a subproblem is the solution of a Schur complement problem.

Hierarchical ($\mathcal{H}$-)matrices provide a powerful technique to compute and store approximations to dense matrices in a data-sparse format. In this talk, we will illustrate how to exploit $\mathcal{H}$-matrix techniques in the construction of efficient preconditioners for saddle point problems. We will conclude with numerical results for a variety of resulting preconditioners.

Preconditioning and convergence in the right norm. **Andy Wathen** (University of Oxford, UK) IC/MT1407/106

The Minimum Residual methods MINRES (for symmetric matrices) and GMRES (for non-symmetric matrices) are widely used for solving the large dimensional linear(ized) systems which derive from approximation of saddle-point (and other) problems. Almost universally preconditioning is used in an attempt to get convergence in a feasible computing time. One affect of the preconditioner with these methods however is to change the norm in which the residual is minimised.

In this talk we will show that appropriate block diagonal preconditioning for the Stokes problem not only guarentees mesh-independent convergence (as proved well over a decade ago in joint work with David Silvester) but also gives convergence in the natural norm for the problem ie. in the 'right' norm!

This is joint work with Howard Elman and David Silvester

Variations on pressure convection–diffusion preconditioners for saddle-point problems. **Raymond Tuminaro** (Sandia National Laboratories, USA) IC/MT1580/106

Pressure convection-diffusion (PCD) preconditioners introduced by Kay, Loghin, and Wathen have been successfully applied to several benchmark flow problems. This talk considers three algorithm variations. The first centers on the development of a new set of boundary conditions for the Poisson and convection-diffusion operators that must be defined for the preconditioner on the pressure space. The new boundary conditions are motivated by Fourier analysis of model flow problems. The second PCD variant is based on a block factorization that resembles the SIMPLE algorithm. The key advantage is that both approximate L and U factors can be employed cheaply within the preconditioner (as opposed to the standard method that uses only the U factor). The third variant considers the reuse of Krylov information between inner preconditioning solves.

Numerical results are given illustrating the benefits to the new variants on a variety of problems.

IC/MP692/106: **The Lagrangian-averaged Navier–Stokes alpha (LANS-α) turbulence model: theory, simulation, and comparison with related models.**

Organiser: Mark Petersen (Los Alamos National Laboratory, USA)

The LANS-α model is a sub-grid scale turbulence model that uses Lagrangian averaged velocity fields to address the turbulence closure. It modifies the nonlinearity of the Navier–Stokes equation, rather than the dissipation, resulting in a turbulence model without enhanced viscosity. LANS-α is a member of a hierarchy of equations developed using asymptotic methods on the Lagrangian in Hamilton's principle. These equations have desirable characteristics, such as conservation of energy and potential vorticity in the absence of dissipation, and Kelvin's circulation theorem.

The LANS-alpha model was introduced in Chen *et al.* (1998), and has since been tested in a variety of numerical simulations. In high Reynolds-number pipe flow, simulations matched observations of mean velocity over several orders of magnitude and showed that the LANS-α model could accurately describe turbulence over a wide range of scales. In forced isotropic turbulence in a three-dimensional periodic domain, the energy spectrum $E(k)$ was proportional to $k^{-5/3}$, as expected (Chen *et al.*, 1998). The LANS-α model was more accurate than a dynamic large-eddy simulation when measured against a reference solution from a high-resolution direct numerical simulation (Geurts and Holm, 2002). A quasi-geostrophic model, developed by Holm and Nadiga (2003), showed that the LANS-α can capture the qualitatively correct time-mean circulation

in the double-gyre problem at a resolution four to eight times courser than a traditional QG model. The LANS-α model was found to affect the baroclinic instability in a two-layer quasi-geostrophic model; it lowers the critical wavenumber, reduces the bandwidth of the instability, and preserves the value of forcing at the onset (Holm and Wingate, 2005).

The LANS-α model is now being tested in primitive equation ocean–climate models, where the gains in the resolution of small-scale processes must be weighed against the computational cost of the turbulence model.

A study of the Navier–Stokes-α model for 2D turbulence. **Evelyn Lunasin** (UC Irvine, USA), Susan Kurien (Los Alamos National Laboratory, USA), Mark Taylor (Sandia National Laboratories, USA), Edriss Titi (Weizmann Institute and University of California, Israel) IC/MT804/106

The Navier–Stokes-α sub-grid scale model of turbulence is a mollification of the Navier–Stokes equations in which the vorticity is advected and stretched by a smoothed velocity field. The smoothing is made by filtering the velocity field over spatial scales of size smaller than α. The statistical properties of the smoothed velocity field are expected to match those of Navier-Stokes turbulence for scales larger than α, thus providing a more computable model for those scales. For wavenumbers k such that $k\alpha > 1$, corresponding to scales smaller than α, there are three possible scalings of the energy spectrum, arising from three dynamical timescales in the model equations: one from the smoothed field, the second from the rough field and the third from a combination of the two. Using two-dimensional turbulence as the test case, we measure the scaling of the spectra from high-resolution simulations of the Navier-Stokes α-model, keeping all parameters other than α fixed. We show that the energy spectrum of the smoothed velocity field scales as k^{-7} in the enstrophy cascade regime, consistent with dynamics dominated by the timescale of the *rough* velocity field. This result implies that the rough velocity field plays a crucial role in the development of the smoothed field even though the latter is the purported model for the Navier–Stokes turbulence. This effect must be taken into account when performing accurate simulations of the α-model.

A new energy-conserving Lagrangian method for the rotating shallow water equations, derived using Voronoi diagrams in Hamilton's action principle. **Matthew Dixon** (Imperial College London, UK) IC/MT920/106

Geometric numerical methods seek to transfer powerful concepts in geometric mechanics to computational fluid dynamics. It is well known that the continuum LANS-α model is derived from Hamilton's action principle and the resulting flow has variational structure. A suitable class of numerical methods for the LANS-α model should also be derived from a discrete Hamilton's principle so that the discrete flow field too has variational structure.

In this talk, I shall present my research on the design of a new Lagrangian method for rotating shallow water with bottom topography which is derived from a semi-discrete Hamilton's action principle. The novel part is the use of a Voronoi diagram to represent the density field. This is dynamically reconstructed at each time step and therefore avoids mesh tangling problems encountered by many Lagrangian methods. This property together with the versatility of the Voronoi diagram makes this method attractive for the long-time simulations on the sphere required for modelling of the earth's climate. The action principle prescribes the form of the discrete gradient and divergence operators required for the semi-discrete shallow water equations to conserve energy. By choosing the form of the discrete curl operator, the semi-discrete divergence and potential vorticity equations are also derived. Potential vorticity is only conserved when the divergence of the discrete curl operator is zero, however. Numerical results of long-time shallow water simulations on an f-plane confirm that this method conserves mass (locally) and energy, and remains stable at larger time steps. We close this talk with a discussion of how this approach can be extended to the LANS-α model by considering the shallow water-α model.

Fluid and numerical stability in the LANS-α model. **Beth Wingate** (Los Alamos National Laboratory, USA) IC/MT4554/106

We present two stability results for the LANS-α model. The first result shows that the LANS-α model's regularization moves the baroclinic instability to lower wave numbers while preserving all the classical baroclinic instability theorems. The second result shows that the LANS-α model, for the fastest waves in climate models, can take a larger maximum allowable time step.

The LANS-α turbulence model in primitive-equation ocean modeling. **Mark Petersen** (Los Alamos National Laboratory, USA), Matthew Hecht (Los Alamos National Laboratory, USA), Darryl Holm (Imperial College London, UK), Beth Wingate (Los Alamos National Laboratory, USA) IC/MT4560/106

POP, the Parallel Ocean Program developed and maintained by Los Alamos National Laboratory, is widely used by the ocean and climate modeling community. Like all numerical models, computational time limits the spatial resolution at which POP can operate; standard climate simulations use grids of 0.5 to 1 degree in latitude and longitude. This resolution does not capture the motion of eddies at the Rossby radius of deformation, and thus lacks the correct energy cascade and heat transport at these scales. The Lagrangian-Averaged Navier–Stokes-α (LANS-α) model, developed by Darryl Holm and colleagues at Los Alamos, improves statistics such kinetic energy, eddy kinetic energy, and temperature profiles with a smoothed advecting velocity and an additional nonlinear term. I will discuss the implementation LANS-α in POP, and present results from a channel-domain experiment that is an idealization of the Antarctic circumpolar current.

Regularization modeling of mixing in stratified turbulence. **Bernard Geurts** (Universiteit Twente, The Netherlands) IC/MT4724/106

The effects of stable and unstable stratification on the turbulent transport in a shear layer are quantified by monitoring global geometric properties of constant density surfaces, such as their area and wrinkling. The flow is simulated using direct and large-eddy simulation, in which regularization modeling for the subgrid scales in the momentum and the scalar equations is adopted and compared to dynamic subgrid modeling. The effects of high Schmidt number in the context of large-eddy simulation is investigated.

On the inertial subrange of symmetry-preserving regularization models for turbulent flow. **Roel Verstappen** (Rijksuniversiteit Gronigen, The Netherlands) IC/MT4727/106

Most turbulent flows cannot be computed directly from the (incompressible) Navier–Stokes equations because they possess too many scales of motion. In the quest for a dynamically less complex mathematical formulation, we consider symmetry-preserving regularizations of the convective nonlinearity. The regularized system should be more amenable to approximate numerically, while its solution has to approximate the low wave-numbers of the Navier–Stokes solution; *i.e.*, at least the first part of inertial subrange is to be approximated properly.

In this talk, we prove, using the arguments of Foias *et al.* (*CRAS I*, 333(5):499–504, 2001), that for any skew-symmetric regularization the energy flux through a wavenumber κ is nearly constant and, hence, independent of the viscosity and κ, throughout a certain range of wavenumber $\kappa_f \leq \kappa \leq \kappa_e$, where κ_f denotes the highest wavenumber of the forcing and κ_e can be estimated in terms of the solution of the regularized system. This rigorous result shows that for $\kappa_f \leq \kappa \leq \kappa_e$ the conditions prevailing in the inertial range for the energy cascade are strictly satisfied for any skew-symmetric regularization of the Navier–Stokes equations. A simple dimensional analysis gives then Kolmogorov's $-5/3$ spectrum.

Lagrangian coherent structures in atmospheric and ocean flows. **Jerrold Marsden** (California Institute of Technology, USA) IC/MT4801/106

We will report on progress towards understanding transport and entrainment processes in ocean and atmospheric flows. Special emphasis will be given to Hurricane dynamics. The computational methodology is based on Lagrangian Coherent Structures, a generalization of invariant manifolds to the time dependent context using George Haller's idea of locating ridges in the finite time Liapunov exponent field. In particular, Typhoon Nabi and Hurricane Katrina will be analyzed and Poincaré-Smale lobe dynamics will be shown to be a dominant transport mechanism.

Mathematical study of certain analytical sub-grid scale of turbulence. **Edriss Titi** (Weizmann Institute and University of California, Israel) IC/MT4806/106

In this talk I will discuss the subtleties and challenges in the mathematical study of the Navier-Stokes and Euler equations. Moreover, I will discuss recent developments in the mathematical study of certain analytical sub-grid scale models of turbulence.

IC/MP520/107: Recent advances in vortex dynamics: theory and computation.

Organiser: Denis Blackmore (New Jersey Institute of Technology, USA)
Co-organiser: Patrick Bontoux (Université Paul Cézanne Marseille, France)
Co-organiser: Chjan Lim (Rensselaer Polytechnic Institute, USA)

The last thirty years have witnessed an explosion of research innovations in vortex dominated flows ranging from Hamiltonian, nonlinear dynamics and classical differential equations analysis of vortex structures to state-of-the-art computational and experimental studies of vortex phenomena. These advances have had a profound effect on applications of fluid mechanics in science, engineering and industrial research, which have led to innovations in aircraft, ship and engine design, and have dramatically enhanced our understanding of ocean dynamics and meteorology, to name just a few areas.

An outstanding slate of distinguished researchers will describe an interesting variety of novel methods and approaches in vortex dynamics, and will discuss applications of their results to problems in science and engineering. The advances presented will embrace the analytical, computational, and experimental aspects of vortical flow research. This minisymposium is a continuation of a very successful series of minisymposia staged by the organizers and their colleagues at major conferences throughout the world over the last several years, the last of which was an embedded session at the GAMM Annual Meeting in Berlin in 2006.

Vortex phenomena in film-cooling flows. **Wolfgang Schroeder** (RWTH Aachen, Germany) IC/MT3745/107

The jet-in-a-crossflow problem is investigated using large-eddy simulations; i.e., the Navier–Stokes equations plus a set of transport equations for several species to simulate a non-reacting gas mixture are solved. Various density and velocity ratios of the outer flow and the injected jet are analyzed and the numerical results are compared with particle-image velocimetry measurements. Conclusions concerning the impact on the cooling efficiency are drawn.

Stability and transitions in fluid dynamics and geophysical fluid dynamics. **Shouhong Wang** (Indiana University, USA) IC/MT4108/107

I shall address in this talk the structure, its formation, its robustness/stability and transitions of fluid flows and geophysical fluid flows, focusing on the connections between the structure in the physical spaces and the dynamics of the flows. This is an important and challenge problem. I shall present some recent progresses, based on two recently developed theories: a geometric theory for incompressible flows and a dynamic bifurcation theory for nonlinear evolution equations. I shall present these theories together with examples on boundary layer separation and on dynamic bifurcation in fluid dynamics and geophysical fluid dynamics to demonstrate the main issues and ideas involved. In particular, I shall present how the Taylor vortices are formed in the Taylor-Couette-Poiseuille flow. This is joint work with Tian Ma.

Motion of integrable four-vortex points on sphere. **Takashi Sakajo** (Hokkaido University, Japan) IC/MT3447/107

We consider the motion of the four vortex points on a sphere when the moment of vorticity vector is zero, which is an integrable dynamical system. With the reduction method that is successfully developed by Aref and Stremler in the integrable planar 4-vortex problem, we give a complete description of the integrable system. We also investigte whether the fully or partial self-similar collapse of the four vortex points is possible or not.

The spherical integrable four-vortex problem is of significance more than just an unsolved problem. In general, a periodic orbit of the N vortex points defines a two-dimensional homeomorphism on the sphere with N fixed points, which is called the N-braids. According to Thurston-Nielsen theory, the N-braids is topologically classified into three types: periodic, pseudo-Anosov(pA) and reducible. The pA map induces a complex behavior, known as the topological chaos. Since it is mathematically proved that the 3-braid on sphere is always periodic, we need to consider the more than three vortex points

in order to obtain the pA N-braids. On the other hand, while it is generally difficult to find a periodic orbit, the integrable four-vortex problem provides us with infinitely many periodic orbits, which helps us find the pA braids. In the present talk, we examine the topological structure of the periodic orbits and observe the chaotic particle mixing due to the pA 4-braids.

Invariant tori in perturbed three-vortex motion. **Denis Blackmore** (New Jersey Institute of Technology, USA), Lu Ting (Courant Institute, NYU, USA), Omar Knio (Johns Hopkins University, USA) IC/MT4357/107

The motion of three-point vortices in an ideal fluid in a plane comprises a Hamiltonian dynamical system that is completely integrable, so it exhibits numerous periodic cycles and quasi-periodic orbits on invariant tori. Certain perturbations of three-vortex dynamics in a plane, such as three-vortex motion in a half-plane, are also Hamiltonian, but not completely integrable. Yet these perturbed systems may still have periodic trajectories and invariant tori close to those for the unperturbed dynamics. Extending recent work by the authors (to appear in J. Math. Phys.), invariant tori approximating those for the unperturbed system are located and analyzed using a combination of classical analysis, asymptotics, and KAM theoretical methods. The results and approximation methods used are then illustrated via simulations for several perturbations of three vortex dynamics such as three vortices in a half-plane, the restricted four vortex problem in the plane, and three coaxial vortex rings.

Dynamics of planar vortex clusters with binaries. **Lu Ting** (Courant Institute, NYU, USA), Omar Knio (Johns Hopkins University, USA), Denis Blackmore (New Jersey Institute of Technology, USA) IC/MT3520/107

We study planar motion of N point vortices with two close together relative to their distance from the others, and call such a pair of vortices a *binary*. It is shown that the leading order representation of the dynamics can be viewed as being comprised of $(N-1)$ vortices, with the binary treated as a single vortex located at its center of vorticity. In particular, the effects of the fast rotaion of the binary appear as higher order corrections. This leads to a two-time and two-length (multiple) scale perturbation problem. We begin by applying this multipe scale scheme to the analysis of a system in the case $N = 3$ with a binary to describe various aspects of the motion. The analysis is then extended to the study of N vortex problems (viewed as perturbations of three vortex dynamics) for systems containing one or more binaries. In addition, the analytical methods developed are used to interpret dynamical features observed in several numerical examples involving three or more vortices with clusters that include binaries.

Decomposing the platonic-solid vortex equilibria on the sphere. **Paul Newton** (University of Southern California, USA) IC/MT3502/107

We will describe a new method of finding and classifying N-vortex relative equilibrium configurations on the sphere. The problem is formulated as one in linear algebra, $A\vec{\Gamma} = 0$, which is obtained by requiring that all intervortical distances remain fixed. One must find a basis set for the nullspace of a non-normal ($A^TA \neq AA^T$) configuration matrix A. The vector $\vec{\Gamma} \in R^N$ is the vector of vortex strengths. The method is described for the 5 Platonic solid configurations on the sphere, where a point vortex is placed at each vertex. The full set of vortex strengths which make these configurations equilibria is surprisingly rich, as obtained by using the singular value decompostion of the configuration matrix A. The talk is based on M. I. Jamaloodeen, P.K. Newton, 'The N-vortex problem on a rotating sphere. II. Heterogeneous Platonic solid equilibria', Proc. Roy. Soc. A, 462, (2006), 3277-3299.

Statistical equilibrium predictions for quasi-2D flows with complex boundaries. **Chjan Lim** (Rensselaer Polytechnic Institute, USA) IC/MT3587/107

Equilibrium statistical mechanics have been applied to macroscopic flows using formulations - canonical or microcanonical in the kinetic energy of the flow - based on either a vortex gas, lattice or spectral representation of vorticity, predominantly in simple domains with either no boundaries or periodic boundary conditions. Most experiments however are performed in no-slip boxes. Furthermore, many interesting phenomena in geophysical flows are found in the category of coupled fluid - container systems such as the those concerning the super-rotation of a barotropic fluid coupled through a torque mechanism to a massive rotating sphere. We give a statistical equilibrium theory - wherein the kinetic energy is not a Hamiltonian and the angular momentum of the fluid can vary - for this class of coupled flows with complex boundaries and show how to obtain predictions of phase transitions under these non-standard conditions. Only the smallest possible set of constraints are retained in our new formulation - energy, total circulation, enstrophy - because complex boundary conditions implies that higher vorticity moments and angular momentum are not conserved even in the absence of viscosity.

Scaling of space-time modes with Reynolds number in two-dimensional turbulence. **Nicholas Kevlahan** (McMaster University, Canada) IC/MT4242/107

It has been estimated that the number of spatial modes (or nodal values) required to uniquely determine a two-dimensional turbulent flow at a specific time is finite, and is bounded by $Re^{4/3}$ for forced turbulence and Re for decaying turbulence. The usual computational estimate of the number of space-time modes required to calculated decaying two-dimensional turbulence is $\mathcal{N} \sim Re^{3/2}$. These bounds neglect intermittency, and it is not known how sharp they are. In this paper we use an adaptive multi-scale wavelet collocation method to estimate for the first time the number of space-time computational modes $\mathcal{N}$ necessary to represent two-dimensional decaying turbulence as a function of Reynolds number. We find that $\mathcal{N} \sim Re^{0.9}$ for $1\,260 \leq Re \leq 40\,400$ over many eddy turn-over times, and that temporal intermittency is stronger than spatial intermittency. The spatial modes alone scale like $Re^{0.7}$. The β-model then implies that the spatial fractal dimension of the active regions is 1.2, and the temporal fractal dimension is 0.3. These results suggest that the usual estimates are not sharp for adaptive numerical simulations. The relatively high compression confirms the importance of intermittency and encourages the search for reduced mathematical models of two-dimensional turbulence (e.g. in terms of coherent vortices).

IC/MP280/107: Particle transport by the atmosphere.

Organiser: Robert McKibbin (Massey University, New Zealand)
Co-organiser: Shigeo Kimura (Kanazawa University, Japan)

Talks and discussion will take place on windborne particle transport, dispersion, trapping and deposition (volcanic ash, pollen, pollution, yellow sand, spray droplets, snow, etc.). Often, these application areas are discussed at specialist conferences on, for example, volcanology, or environment, or horticulture, etc. This minisymposium will bring these researchers together to discuss methods, techniques and share good practice in solving these complex geophysical problems.

Topics and applications include particle transport/dispersion/trapping; dispersion in forest canopies; models of tephra dispersal/volcanic ashfall; yellow sand; numerical simulation of pollutant transport in the atmosphere; droplet motion and sprays; particle tracking models; wildfires; snow dispersion.

Sedimentation of volcanic particles. **Costanza Bonadonna** (Université de Genève, Switzerland), Jeremy Phillips (University of Bristol, UK) IC/MT3056/107

Particle fallout is one of the main products of explosive volcanic eruptions and occurs after material has been explosively ejected from a vent producing an eruption column, which is a buoyant plume of particles (tephra) and gas rising typically to stratospheric levels. Tephra can be transported in the atmosphere for significant distances, leading to dispersal over thousands of square kilometers around the volcano, and is a significant hazard causing respiratory problems to human and animals, serious damage to buildings and affecting economic sectors such as agriculture and tourism for many years after an eruption. The study of tephra dispersal represents an important aspect of hazard mitigation but it also provides important insights into eruptive-column dynamics. As a result, the study of tephra sedimentation has followed two main directions: (i) the detailed investigation of the dynamics of tephra fallout and (ii) the mitigation of tephra hazards. The first approach tries to capture the complex processes of particle transport in volcanic plumes and in the atmosphere, using a mixture of deterministic and probabilistic methods, whereas the second approach focuses on reliable mapping of tephra dispersal using predominantly probabilistic methods. In this talk we review the formulation of existing models of tephra dispersal, and discuss recent advances in computation methods that have allowed development of more sophisticated formulations. In particular, we identify important processes such as particle aggregation and the effects of particle shape on settling velocity that are currently poorly understood, and identify key areas of future development, including integration with remote sensing methods to improve model validation.

High-resolution numerical simulations of buoyant plumes from intense heat sources and implications for particle transport. **Philip Cunningham** (Florida State Universty, USA) IC/MT2616/107

Buoyant plumes arise routinely in a wide variety of geophysical contexts, examples of which include plumes from wildfires and volcanoes; many such plumes are important for the transport of particles in the atmosphere. Much information about the macroscale aspects of buoyant plumes can be obtained by application of the so-called entrainment hypothesis, which assumes that the flow is self-similar well above the source and that the mean inflow across the edges of the plume is proportional to the mean vertical velocity along the plume centerline. Although this approach has largely been successful in describing plume behavior over a wide range of scales, experimental estimates of the entrainment rate in buoyant plumes have varied widely, apparently due to the role of the coherent vortices that are generated in the near-source region and that impact entrainment in the far field. Moreover, for plumes from intense heat sources in the presence of nonuniform ambient flows, the assumption of similarity may break down and numerical solution of the governing equations is required. Well-resolved numerical simulations of thermal plumes are still somewhat rare, however, and a detailed understanding of the turbulent dynamics of buoyant plumes remains elusive.

In this talk, the structure and dynamics of buoyant plumes arising from isolated heat sources both in calm conditions and in the presence of an ambient cross flow are examined using a large-eddy simulation (LES) model. The basic structure and behavior of the simulated plumes will be presented, along with the dependence of this structure and behavior on parameters such as the speed of the ambient cross flow and the intensity of the heat source (i.e., the buoyancy forcing). Results from the LES model illustrate the role and significance of coherent vortices in plume dynamics. Indeed, in the presence of an ambient flow, the interaction between the vorticity in the cross flow boundary layer and the buoyancy generated vorticity in the plume results in the generation of several types of coherent vortical structures that dominate the structure and behavior of the plume. Finally, the dynamics of buoyant plumes in the presence of more complex environmental flows will be considered, such as the case of buoyant plumes interacting with density currents. The implications of the results for particle transport in the atmosphere will be addressed.

Organized flow structure and turbulent diffusion in a forest canopy. **Shigeo Kimura** (Kanazawa University, Japan) IC/MT1222/107

The wind velocities and turbulent properties in a plantation of *Quercus variabilis* Blume and *Quercus serrata* Murray belonging to deciduous tree were measured with ultrasonic anemometers. The values of the eddy diffusion coefficient during summertime have about one half of those in winter. When the density of the leaves is high, the dependency of the eddy diffusion coefficient on wind velocity is found to be very weak. The measurements imply that tree leaves reduce eddy scales by behaving as elastic obstacles.

When the fluctuating pattern of the vertical and horizontal velocities, and the temperatures at the height of 16m during summertime are analyzed as time series data, it is found that there is a dominant frequency of about 0.01 Hz in the time series. It is conceivable that the eddy-like structure whose center is positioned on the boundary of forest canopy and the open air is moving horizontally with an average velocity. The appearance of intermittent turbulent flows of sweep and ejection, which closely relate a horizontal wind velocity with a vertical one, also shows that a vertical coherent structure is formed in the canopy. In addition, the time interval between different vertical positions, indicates an eddy structure, where the flow in the lower half of the forest always precedes that in the upper half and in the open atmosphere, i.e. an elongated eddy is inclined backward and is centered on the canopy boundary.

Analytic solutions to the particle transport equations for a non-uniform atmosphere . **Robert McKibbin** (Massey University, New Zealand) IC/MT407/107

Solid and liquid particles ejected into the atmosphere by volcanic or hydrothermal eruptions, or dust and sand swept up by storms, are subsequently dispersed by atmospheric wind currents. The particles fall under gravity while being advected by the mean wind and dispersed by turbulence. Particle sizes are generally not uniform, and may change during flight, either by particle coalescence and/or fragmentation, or, in the case of fluids, by evaporation. The wind (speed, direction and dominant turbulence length scales) may also change with elevation and with time.

A quantitative model that reflects these influences on particle dispersal is outlined. The elevation-dependent features listed above are included, as well as time-dependent settling speed. In particular, analytic solutions to the advection-dispersion equations that describe the motion of the particles are found. The variation of conditions with elevation are treated by using a piecewise-constant wind velocity and dominant turbulence length scale and settling speed; this is the way that data are provided for most of the numerical schemes currently available.

Numerical results calculated directly from the derived analytical formulae are used to provide examples of the method.

IC/MP216/107: Mixing in industry and the environment.

Organiser: Jean-Luc Thiffeault (Imperial College London, UK)
Co-organiser: Emmanuel Villermaux (Université de Provence Aix-Marseille I, France)

Stirring and mixing of substances by fluid flow has been an area of active research for many decades, a reflection of its great importance for geophysical as well as industrial applications. The types of flows considered range from extremely viscous (e.g. food processing) to turbulent (e.g. combustion); from small scales (e.g. microfluidics) to large scales (e.g. atmospheric flows). Experiments have recently improved dramatically due to progress in digital optical technology. Mathematically, tools from dynamical systems, partial differential equation analysis, and stochastic analysis have been applied fruitfully to mixing problems. This minisymposium focuses on recent experiments and theory, and how these impact environmental and industrial applications.Topics addressed include:

- Measurements of stirring and mixing properties of flows;
- Optimization techniques for mixing flows;
- Measures of efficiency and diagnostics of mixing;
- Mathematical foundation of mixing:
  - The role of topological constraints;
  - Recent work on describing the concentration distribution;
  - The computation of rates of mixing.

Of particular interest is the identification of new industrial challenges for the mixing community, as well as determining which recent techniques are most promising for practical applications.

The finest scales in turbulent mixing of passive scalars. **Jörg Schumacher** (TU Ilmenau, Germany) IC/MT1183/107

The mixing of passive scalars in turbulent flows is a process with numerous applications reaching from spreading of pollutants in the stratosphere and the transport of salinity in the ocean to non-premixed combustion of fuel. Frequently, the Schmidt number which is formed as the ratio of the kinematic viscosity to the diffusivity of the passive scalar exceeds the unit value significantly. In this case, the viscous-convective range of scalar turbulence is established between the Kolmogorov dissipation scale of the flow and the Batchelor diffusion scale of the scalar. Very fine scalar filaments which are associated with strong gradients can be generated in this regime similar to chaotic advection.

The following work aims at studying the processes which cause the finest scales in turbulent mixing. We will discuss statistical and geometrical aspects of the dynamics on sub-Kolmogorov and Kolmogorov scales. As it will turn out, a continuum of local diffusion and dissipation scales is present rather than one characteristic cut-off scale. This is intimately related to the strongly intermittent nature of the dissipation rate fields for both, the passive scalar and the advecting flow.

Our investigations are based on direct pseudospectral simulations in a periodic box with large resolutions. The flow is a homogeneous isotropic turbulence which is generated by a large-scale random forcing. Scalar tubulence is sustained by an outer constant mean scalar gradient. Much effort has been put into the sufficient spectral resolution here, which significantly exceeds the usually adopted ones. This limits the range of accessible Taylor microscale Reynolds numbers on one side, but opens the opportunity for detailed studies in the far-dissipation range of the flow on the other side. Therefore, we will also present some results on the velocity statistics in the viscous range, such as statistical properties of higher order velocity gradient moments.

Chaotic mixing in industrial devices. **Emmanuelle Gouillart** (CEA Saclay, France), Olivier Dauchot (CEA Saclay, France), Stéphane Roux (Saint-Gobain, France), Jean-Luc Thiffeault (Imperial College London, UK) IC/MT2639/107

Low-Reynolds-number mixing devices are widely used in many industrial applications, such as food engineering and polymer processing. Flows are then laminar and mixing can thus be problematic without the help of turbulence. Understanding the mechanisms of laminar mixing is therefore crucial to reduce the energetic and environmental cost of mixing installations. To this respect, we know since the eighties and the introduction by Aref of the notion of *chaotic advection* [H. Aref, "Stirring by chaotic advection", J. Fluid Mech. **143**, 1984] that flows with simple time dependency can nonetheless exhibit very complicated Lagrangian dynamics due to chaos, and hence good mixing.

We report on experiments of chaotic mixing conducted in a closed vessel where a moving stirrer mixes a low-diffusivity dye with viscous fluid, and analyze quantitatively the rate at which the initial blob of dye is mixed by the flow. We find that the decay of dye concentration is slower than expected from most previous theoretical studies. The peripheral fluid region "sticking" to the vessel wall is indeed shown to slow down the whole mixing process despite exponential stretching occurring in the bulk. A minimal one-dimensional model allows us to mimic this phenomenon and yields scalings for the concentration distributions similar to the experimental observation, thus shedding light on the basic mechanisms of mixing in batch stirring devices.

Shear effects on passive scalar spectra. **Dario Vincenzi** (Max-Planck-Institut Göttingen, Germany) IC/MT2713/107

The effects of a large-scale shear on the energy spectrum of a passively advected scalar field are investigated. The shear is superimposed on a turbulent isotropic flow, yielding an Obukhov–Corrsin $k^{-5/3}$ scalar spectrum at small scales. Shear effects appear at large scales, where a different, anisotropic behaviour is observed. The scalar spectrum is shown to behave as $k^{-4/3}$ for a shear fixed in intensity and direction. For other types of shear characteristics, the slope is generally interme-

diate between the $-5/3$ Obukhov–Corrsin and the -1 Batchelor values. The physical mechanisms at the origin of this behaviour are illustrated in terms of the motion of Lagrangian particles. They provide an explanation for the scalar spectra that are shallow and dependent on the experimental conditions in shear flows at moderate Reynolds numbers.

Work done in collaboration with A. Celani, M. Cencini, E. Villermaux, M. Vergassola.

Clusters and voids of inertial particles transported by turbulence. **Massimo Cencini** (Università degli Studi di Roma "La Sapienza", Italy) IC/MT1170/107

Small impurities like dust or droplets suspended in turbulent flows are finite-size particles whose density may differ from that of the fluid and thus cannot be modeled as fluid tracers. The description of their motion, which is much more complex than that of fluid tracers, must account for their finite response time, i.e. their inertia –whence the name *inertial particles*. Remarkably such particles display strong spatial inhomogeneities even if the carrier flow is incompressible, a phenomenon known as *preferential concentration*, whose statistical description is an open issue with many industrial and environmental applications. We mention rain droplets formation and spray combustion in Diesel engines. Inertial particles are also relevant to aerosols, pollen or chemicals dispersion in the atmosphere.
Results of direct numerical simulations are presented here for inertial particles transport in homogeneous, isotropic, fully developed turbulence. The statistics of their distribution is investigated at very small scales where they form (multi)fractal objects; such clustering is very efficient for particles lighter than the fluid which transport them. At larger scales, particles do not cluster into fractal objects and different approaches are needed for understanding their statistics; here voids are the dominant structures for heavy particles. Consequences of these observations for the development of models for inertial particles transport will be also discussed.

Stretching fields and lines in the transport dynamics of the Western Mediterranean. **Emilio Hernandez-Garcia** (Universitat de les Illes Balears, Spain) IC/MT2580/107

Hyperbolic points and their manifolds organize the phase space of dynamical systems. In the Lagrangian description of fluid transport they determine transport routes and mixing properties. Stretching fields are correlated with these structures and thus provide an heuristic method to approximate them. Calculations of the above mentioned objects has been performed in simplified model flows since some time ago. More recently, increased computer power and theoretical insight are allowing their identification in realistic and in observed fluid flows. In this talk I will describe recent work on the location of Lagrangian structures in velocity fields obtained from realistic simulations and from satellite altimetry of the surface layers of the Mediterranean sea. Finite Size Lyapunov exponents are found to be useful quantities to characterize stretching and compressing distributions, and their implications for mixing. Direct calculation of hyperbolic points and their stable and unstable manifolds turns out to be more complex, but allows the use of the tools of lobe dynamics to characterize fluid transport. This is illustrated here for the surface circulation in the Balearic front area.

Chaos, mixing and DNA analysis in pulsed source–sink systems. **Mark Stremler** (Virginia Tech, USA) IC/MT3053/107

DNA microarray analysis is a fluid-based, high-throughput screening technology that is helping redefine the approach to discovery in biomedical research. DNA 'target' molecules in solution are identified according to their sequence through interactions with complementary 'probe' molecules immobilized on the microarray. The standard practice of relying on diffusive 'target' transport imposes severe limitations on the speed and reliability of this technology. The logical approach is to move these molecules with an imposed flow. Efficient operation requires that the solution be well mixed and that individual molecules do not continually revisit the same area of the microarray, which suggests that chaotic transport will enhance performance. A system of pulsed source-sink pairs can produce chaotic advection in the high-aspect-ratio domains needed for microarray analysis. An analytical model of source-sink flow in a Hele-Shaw cell is used to characterize the behavior of the system as the parameters are varied, and optimal system performance is identified using standard chaos diagnostics. These analytical results are compared with an experimental analysis of mixing in a prototype system. Finally, experimental DNA hybridization results clearly demonstrate the significant signal enhancement that is produced by the presence of chaos in the system. This enhancement results in reduction of hybridization times by as much as an order of magnitude while significantly increasing the sensitivity of the test and the accuracy of the results.

Mesohyperbolicity in aperiodic flows. **Igor Mezić** (University of California, Santa Barbara, USA) IC/MT3052/107

A number of different criteria have been proposed for dynamical systems analysis of mixing in incompressible fluid flows with aperiodic time-dependence. Here we show that several of these criteria can be unified into a single finite-time criterion that depends on the Lagrangian average velocity gradient tensor. Okubo-Weiss criterion is obtained for the limit when the time interval T goes to zero, while the Lyapunov exponent criterion is obtained in the case when $T \to \infty$. Examples of controlled flows, microfluidic flows and oceanographic flows are studied.

The linked twist map approach to fluid mixing. **Rob Sturman** (University of Leeds, UK) IC/MT2867/107

Fluid mixing is a topic which spans a wide range of applications and disciplines. In recent years the tools of topological dynamical systems have been successfully employed to place the subject of chaotic mixing on a mathematical footing. In this talk we argue that the field of ergodic theory will play the next crucial role in supplying results on mixing which have a direct impact on applications.

In particular, the linked twist maps of the now classical ergodic theory literature are systems for which ergodicity, strong mixing and the Bernoulli property can be shown for sets of full measure. We show that such systems can be viewed as paradigm models for the design of fluid mixers. We give examples from diverse areas, such as microfluidics, granular flow and DNA hybridization to support this, and emphasize the key directions in which the theory could be advanced to allow a greater connection with applications.

IC/MP284/108: Influence of surfactant on interfacial flows.

Organiser: Michael Siegel (New Jersey Institute of Technology, USA)
Co-organiser: Michael Booty (New Jersey Institute of Technology, USA)

Interfacial fluid dynamics provides fertile ground for the development of analytical and numerical techniques in the study of free boundary problems. A particularly challenging class of problems arises from consideration of the effect of surfactant on the deformation and evolution of fluid interfaces. This is due to the complexity of the surfactant transport problem, which introduces coupling between surface and bulk surfactant concentrations and fluid motion, and the dependence of surface tension on surfactant concentration. Numerical computations are further complicated by the need to track highly distorted interfaces and to resolve thin boundary layers of bulk surfactant concentration. Challenges also occur in understanding how surfactants influence or may be used to control interfacial dynamics in biological and chemical applications.

The talks in this minisymposium report on recent advances in paradigmatic problems of surfactant dynamics. These include surfactant-driven instabilities in pipe and channel flows, surfactant effects on the pinch-off of bubbles and jets, and the fingering instability of a surfactant-laden droplet. The final talk presents recent results on the modeling and simulation of vesicles made of lipid bilayers, and discusses the parallels between the dynamics of vesicles and surfactant covered drops.

Surfactant-driven instability in two-fluid pipe and channel flows. **Mark Blyth** (University of East Anglia, UK) IC/MT1220/108

We consider the role of insoluble surfactant in a variety of interfacial flow phenomena. First, two-layered viscous channel flow is shown to become unstable at zero Reynolds number to a linear mode associated with the presence of surfactant. Nonlinear boundary integral calculations show that the growing wave begins to steepen and may either saturate or overturn and break. Nonlinear results at arbitrary Reynolds number computed using an immersed interface method show similar effects. The effect of both small and large wall corrugations are quantified via both linear and nonlinear calculations. Axisymmetric core annular flow in the presence of surfactant is also considered. In this case, no new instability is introduced by the surfactant; nevertheless it still has a generally destabilising influence. Nonlinear computations at arbitrary Reynolds number reveal that the surfactant plays an important role in determining the morphology of the interface, including the development of pointed waves, slugs and drops.

Spreading, dewetting and fingering in surfactant-driven thin liquid films. **Omar Matar** (Imperial College London, UK) IC/MT1367/108

The spreading of surfactant on thin liquid films is central to a number of applications including coating flow technology, surfactant replacement therapy and oil-spill cleanup. The spreading is driven by surfactant concentration gradients, which give rise to gradients in surface tension and Marangoni stresses that spread the surfactant in the direction of higher surface tension and give rise to large deformations in the thin film. Following the deposition of a droplet of surfactant solution on an initially undisturbed thin film, a thickened front is formed at the surfactant leading edge, which advances downstream of a severely thinned region, near the original point of deposition. A number of experimental studies have shown that the spreading process is accompanied by intriguing physical phenomena. Examples of such phenomena include a fingering instability that targets the thinned region. The shape of the fingers and the degree of their branching depends on the surfactant concentration and on the film thickness. Other examples involve autophobing and subsequent dewetting, which occur in situations wherein the surfactant head-group is attracted to the solid substrate underlying the liquid film through electrostatic interactions. In this talk, we present our model derived using lubrication theory which comprises a system of coupled evolution equations for the film thickness and surfactant concentration; the surfactant is allowed to exist in the bulk as a monomer and a micelle (if the concentration exceeds the critical micelle value) and on both the air-liquid and liquid-solid interfaces. Using transient growth analyses and transient numerical simulations of the two-dimensional evolution equations we demonstrate the mechanism responsible for the fingering instability. We also show results that capture the main observations in the autophobing experiments by including a disjoining pressure term in our model, which depends on the presence of surfactant and its basal adsorption.

The effect of surfactant on bubble and thread dynamics. **Michael Siegel** (New Jersey Institute of Technology, USA), Michael Booty (New Jersey Institute of Technology, USA) IC/MT3406/108

After a brief overview of the role of surfactants in the dynamics of interfacial fluid flow, we focus on two examples in the dynamics of surfactant-laden bubbles. In the first example, a surfactant-laden bubble is rapidly stretched by an imposed flow to form a dumb-bell shape, then the imposed flow is reduced to zero so that the bubble evolves solely under the action of surface tension. The usual mode of clean bubble breakup is changed by surfactant and a slender, quasisteady thread forms connecting two parent bubbles. The dynamics is elucidated by a combination of direct numerical simulation and long wave asymptotic analysis. In the second example, a surfactant-laden bubble is stretched by a steady extensional flow. Asymptotic analysis based on the slenderness of the bubble is used to find steady bubble shapes in terms of the capillary number or strain-rate of the imposed flow. At sufficiently large strain rates, a long wave analysis models the formation of experimentally observed tip-streaming filaments from the bubble end-points. In both examples, the role of effects such as small interior fluid viscosity and small diffusion of both adsorbed and dissolved surfactant is discussed.

Dynamics of surfactant-covered drops in linear flows. **Petia Vlahovska** (Dartmouth College, USA) IC/MT3425/108

Surfactants modify interfacial properties and significantly affect drop behavior in flow. I will present a systematic study of the dynamics of a drop, which is covered with a monolayer of insoluble surfactant, in linear viscous flows, both unbounded and in the presence of a wall. The effect of viscosity contrast is included. Analytical expansions for weak flows and high viscosity drops are developed. Numerical results with three-dimensional boundary integral simulations are used to explore large deformations. The results show that surfactant generally enhances drop deformation, certainly under small-deformation conditions. The steady-state drop shape and surfactant distribution are independent of viscosity contrast in straining flows (e.g. hyperbolic, axisymmetric strain). The drop shape and surfactant distribution are insensitive to viscosity contrast under small deformation conditions for any linear flow; the effect of the rotational component at higher-order. Under finite deformation conditions, the distortion of the drop shape and surfactant distribution decreases for large viscosity contrast in flows with rotation. The theory quantifies the effect of surfactant on the rheology of dilute emulsions, and predicts non-Newtonian features such as shear thinning viscosity and normal stress. I will also present calculations of the far-field hydrodynamic interactions of a surfactant-covered drops, and results about collision efficiencies and migration away from a bounding wall.

Convective instability and optimal growth in flow over a backward-facing step. **Dwight Barkley** (University of Warwick, UK), Hugh Blackburn (CSIRO, Melbourne, Australia), Spencer Sherwin (Imperial College London, UK) IC/CT3197/102

Flow over a backward-facing step has long been a prototype for transition to turbulence in separated shear flows. Despite this, there has never been a close correspondence for this flow between what is seen in experiments and what is found in numerical stability computations. In particular, linear stability analysis has show that this flow is linearly (absolutely) stable well beyond the Reynolds numbers at which experiments show the flow to become unsteady. For some time this discrepancy has been thought to be due to the fact that the flow is convectively unstable, but previous numerical demonstrations of the convective instability of the flow have been rather qualitative.

In this talk we present result from an analysis of the optimal growth problem for the backward-facing step. We discuss how this correctly addresses the issue of convective instability of the flow. We give results from highly accurate spectral-element computations results showing pairs of optimal modes which are strongly amplified by the separated shear layer. Moreover, the evolution of these modes closely resembles what is seen in experiment.

Jeans' gravitational instability of a thermally-conducting, unbounded, partially-ionized plasma. **Aiyub Khan** (Jodhpur, India) IC/CT3898/102

The gravitational instability of an infinitely extending homogenous, partially ionized plasma, permeated by an oblique magnetic field, has been studied to investigate the effects of Hall currents, finite conductivity, viscosity, collision with neutrals and thermal conductivity on the growth rate of the disturbance. The dispersion relation obtained has been solved numerically, and it has been found that Hall currents and collision with neutrals have a destabilizing influence on the growth rate while the other mechanisms reinforce the gravitational instability. JeansŠ criterion, derived within a purely hydrodynamic framework, has been rediscussed along a nonextensive kinetic theory. A new JeansŠ criterion was deduced, which depends on the nonextensive parameter q and the standard JeansŠ wave number is recovered in the limiting case $q = 1$.

Key words: Partially Ionized; JeansŠ Criterion; Thermal Conductivity. In collaboration with Shaista Shaikh

Instabilities in buoyant flows under localized heating. **Ana Mancho** (Consejo Superior de Investigaciones Científicas, Spain), Maria Cruz Maria Cruz (Universidad de Castilla-La Mancha, Spain), Henar Herrero (Universidad de Castilla-La Mancha, Spain) IC/CT2364/107

We study, from the numerical point of view, instabilities developed in a fluid layer with a free surface, in a cylindrical container which is non-homogeneously heated from below. In particular we consider the case in which the applied heat is localized around the origin. An axisymmetric basic state appears as soon a non-zero horizontal temperature gradient is imposed. The basic state may bifurcate to different solutions depending on vertical and lateral temperature gradients and on the shape of the heating function. We find different kinds of instabilities: extended patterns growing on the whole domain which include those known as targets, and spiral waves. Spirals are present even for infinite Prandtl number. Localized structures both at the origin and at the outer part of the cylinder may appear either as Hopf or stationary bifurcations. An overview of the developed instabilities as functions of the dimensionless parameters is presented in this article.

Stability of the non-isothermal flow between co- and counter-rotating disks. **Artur Zielinski** (TU Poznan, Poland), Ewa Tuliszka-Sznitko (TU Poznan, Poland) IC/CT2380/102

The 3D DNS computations are performed to study the isothermal and not-isothermal transitional flow between two co- and counter-rotating disks enclosed by two rotating cylinders. Computations have been performed for the wide range of Reynolds numbers and different end-wall conditions including throughflow. For chosen examples 3D LES computations are performed. The investigation of the lam.-turb. transition process inside the inter-disk 3D rotating flow is of great interest for the internal aerodynamics of engines. The flow is described by 3D Navier-Stokes, energy and continuity equations. To take into account the buoyancy effects induced by the involved body forces the Boussinesq approximation is invoked. Numerical computations are based on a pseudo-spectral Chebyshev-Fourier method. The time scheme is semi-implicit and second-order accurate [1]. For LES computations, a Lagrangian dynamic sub-grid model of turbulence is used, [2]. In this paper we studied the spatial structures which appeared in different stages of the lam.-turb. transition process. We considered cavities of the aspect ratio ranging from 9 to 11 and curvature parameters Rm=1.5Ů3.0. For sufficiently large negative value of the rotational rate of disks we observed the instability pattern which corresponds to the negative spirals described in [3]. We investigated influence of the thermal Rossby number on lam.-turb. transition process. Distributions of the local Nusselt numbers obtained on the heated rotating disk showed good agreement with the experimental results. For chosen examples, DNS and LES results are compared.

Numerical instability of shock waves in conservative difference approximation of the compressible Euler equations. **HIdeaki Aiso** (Institute of Aerospace Technology, Japan) IC/CT3013/106

It is known that some instability may happen along with shock waves in numerical computation for the compressible Euler equations. Even with the discretization by Godunov scheme, which is considered one of the most natural discretization, such instability may happen.
Mentioned by Quirk in 1994, the instability of numerical carbuncle phenomenon has been discussed in several articles. The instability may happen in multi-dimensional computation but not in one dimensional computation, and usually destroys the numerical computation. On the other hand the linear instability of one dimensional shock profile has been also discussed. But this kind of instability does not seem to cause any fatal error while it does harm with the numerical convergence to some expected stable state. The relation between two kinds of instability phenomena above is not enough analyzed.
We observe the linear stability of numerical computation of fixed and progressing shock waves using Godunov scheme in one and multi- dimensional cases by observing the linearized system of all of the calculated variables in the computation. The method of analysis is first proposed by Moschetta et al. We extended the analysis to the case of progressing shock waves and obtain the following results. (1)In cases of completely upwind computation of progressing shock wave, the occurrence of carbuncle phenomenon and the linear instability of multi-dimensional numerical system show rather exact coincidence. It means that the carbuncle instability is caused by the linear instability in the cases. (2)In cases of fixed shock wave the occurrence of carbuncle and the linear instability shows some coincidence but it is not exact. Some relation with linear instability of one dimensional shock profile is also observed.

Slowly moving shock cases also show some critical situation. We also discuss the multi-dimensionality of carbuncle phenomenon from the numerical experiments.

Octopus-shaped instabilities of evaporating droplets. **Nebojsa Murisic** (New Jersey Institute of Technology, USA), Lou Kondic (New Jersey Institute of Technology, USA) IC/CT782/108

We report on curious phenomena recorded recently during spreading of evaporating isopropyl alcohol droplets on silicon wafer surfaces (for movies, see http://m.njit.edu/~kondic/thin_films/octopi.html). Novel *octopus*-shaped instabilities were noticed appearing close to the contact line. In addition to our desire to understand the instability, a motivation for this study is the fact that instabilities occurring in evaporating droplets are the signature of rich dynamics which influences drying, dewetting, and even solid residue deposition which can deteriorate electrical and other properties of the semiconductor devices.
After discussing the experimental results, we present a lubrication-based mathematical model describing spreading of volatile drops on non-isothermal solid substrates. We show that evaporation is not limited by diffusion of vapor into surrounding gas phase, and therefore utilize the one-sided model, where the problem is to be solved for liquid only. The starting point in the model development are Navier–Stokes equations in 2D for incompressible viscous fluid, accompanied by the energy equations for liquid and solid phase, and appropriate boundary conditions. Application of lubrication approximation yields a single nonlinear PDE for evolution of drop thickness. We employ finite-difference-based numerical algorithm to simulate drop evolution and perform linear stability analysis (LSA) of the full governing equation. Through LSA and numerical simulations, we show that essential factors influencing occurrence of octopus-shaped instabilities include volatility of liquid, and thermal conductivity of both liquid and solid.

The presented theoretical work was done in collaboration with the experimental work by Dr. Y. Gotkis (KLA Tencor) and Dr. I. Ivanov (Blue29).

IC/CTS4933/10: Free surface, flow, fluid–structure stratified.

Organiser: Daniel Anderson (George Mason University, USA)

Approximate factorization methods for free-surface flows. **Cassio Oishi** (Universidade de São Paulo, Brazil) IC/CT846/101

When solving the unsteady incompressible Navier–Stokes equations the velocity and pressure fields are coupled, giving rise to a large system equations. Such systems can be difficult to solve, not just because of their nonlinearity, but their very size can make the problem intractable. To overcome this difficulty one approach is to apply a projection method to decouple the Navier-Stokes equations. In the context of the Marker-And-Cells method [F.H. Harlow and J.E. Welch, Physics of Fluids, 8 (1965) 2182-2189], which is one of the first techniques for successfully solving free surface flow problems, this work investigate the order of accuracy of projection methods when applied to free surfaces flows. This investigation is carried through the method of approximate factorization (introduced initially for Navier-Stokes equation by [J.K. Dukowicz and A. S. Dvinsky, Journal of Computational Physics, 102 (1992) 336-347]). In this work we shall show that it is possible to apply the method of approximation factorization to derive a strategy for obtaining a second-order projection method for free surface flows. It will be noted that the order of the method is not influenced by how one updates the pressure and the boundary conditions. This will emerge naturally from an analysis of the error term. Numerical results illustrating the different performances of the two approaches will be presented for a 2D free surface flow problem. Examples of the second-order projection method for 3D free surface problems will also be presented.

Work done in collaboration with Jose A. Cuminato and Valdemir G. Ferreira

Homogenization theory for nonlinear free-boundary problems. **Daniel Anderson** (George Mason University, USA) IC/CT2068/100

We explore homogenization theory applied to nonlinear free-boundary problems. Problems under consideration include simple one-dimensional problems such as the draining of a horizontally-layered porous material, slender two-dimensional gravity currents slumping in a heterogeneous porous media, and fully two-dimensional gravity currents. The description we consider uses a sharp moving interface to define the fluid region in each case. We discuss details of how these problems can be homogenized with respect to rapidly-varying permeability fields to obtain effective, leading-order, descriptions of each flow. Of particular interest is the possibility of identifying corrections to the leading-order homogenization results. Such corrections lead to approximate solutions that incorporate more completely the physical features of the problem associated with the rapid variations.

Numerical techniques for ice-mass dynamics simulation by using a complete shallow ice approximation. **Carlos Vázquez Cendón** (Universidade da Coruña, Spain), Natividad Calvo-Ruibal (Universidade de Vigo, Spain), José Durany (Universidad de Vigo, Spain), Raquel Toja (Dep. Mathematics, Faciulty of Informatics, Campus, Spain) IC/CT2140/103

In this work a complex coupled shallow ice model governing thermal, hydrodynamic and mechanical processes in large ice masses dynamics is proposed and solved by means of efficient numerical techniques. For this, the PDE system governing the upper ice sheet profile (1), the velocity field, the temperature and the basal magnitudes is posed and a fixed point iteration which sequentially treats each subproblem is developed (2). In addition to the the nonlinear equations, free/moving boundary problem formulation for unknown domains are required. Several numerical techniques have been considered: 1-d and 2-d first order characteristics methods for time discretization, 1-d and 2-d finite elemens for spatial discretization, duality and Newton methods for nonlinear problems, numerical quadrature formulas for velocity computation, etc. (2). For the numerical simulation a software toolbox application has been developed (3). Furthermore, in order to save computing time in real applications, appropriate parallel implementations of BICGSTAB linear systems solver combined with mean grain parallel techniques have been applied (4).

Numerical modelling of fluid-structure interaction with application in hemodynamics. **Anna Zauskova** (TU Hamburg–Harburg, Germany), Mária Lukáčová (Hamburg University of Technology, Germany) IC/CT1270/105

The aim of this work is the numerical approximation of the blood flow in compliant vessels. In this mathematical model we consider blood as a non-Newtonian fluid in a domain, which is deformed by acting of the fluid forces. In this fluid-structure interaction problem, the Navier-Stokes equations with non-linear stress tensor for the fluid are coupled with the domain deformation equation governing on the deforming part of the boundary. A global iterative method with respect to the domain deformation is used to decouple the fluid and structure. Some numerical experimets are presented and the convergence of the global iterative method can be observed. We will also present theoretical analysis of the mathematical model for shear dependent non-Newtonian fluids in compliant vessels.

Corner singularities of compressible Navier–Stokes equations on polygonal domains. **Jae Ryong Kweon** (Pohang Univ. of Science and Technology, Republic of Korea) IC/CT4316/104

In this talk I will discuss the compressible Navier–Stokes equations on polygonal domains. The solution velocity is split into singular plus regular parts near concave corners. The stress intensity factor is a function of time variable, has certain regularity. By a formula of pressure we observe propagation of corner singularity along the streamlines emanating from the corners and unboundedness of derivatives of pressure there. An increased regularity for the remainder is obtained.

Complete analysis of an ideal rotating uniformly-stratified system of ODEs. **Bhausaheb Desale** (University of Mumbai, India) IC/CT2611/101

In this paper we discuss a system of six coupled ODEs which arise in ODE reduction of the PDEs governing the motion of uniformly stratified fluid contained in rectangular basin of dimension $L \times L \times H$, which is temperature stratified with fixed zeroth order moments of mass and heat. We prove that this autonomous system of ODEs is completely integrable if Rayleigh number $Ra = 0$ and determine the stable, unstable and center manifold passing through the rest point and discuss the qualitative feature of the solutions of this system of ODEs.

Regularity for the Navier–Stokes equations with slip boundary condition. **Hyeong-Ohk Bae** (Ajou University, Republic of Korea) IC/CT2911/103

For the Navier–Stokes equations with slip boundary conditions, we obtain the pressure in terms of the velocity. Based on the representation, we consider the relationship in the sense of regularity between the Navier-Stokes equations in the whole space and those in the half space with slip boundary data.

Group-invariant solution for a free 2D turbulent jet with eddy viscosity. **David Mason** (University of the Witwatersrand, South Africa), Des Hill (University of Western Australia) IC/CT3690/108

A free two-dimensional turbulent jet described by eddy viscosity is analysed. A Lie point symmetry generator of the two-dimensional boundary layer equations for the turbulent jet exists provided the eddy viscosity satisfies a first order quasi-linear partial differential equation. The general form of the group invariant solution for the fluid velocity and the eddy viscosity is derived. The hypothesis due to Prandtl that the eddy viscosity is constant across a turbulent jet is investigated. Using the group invariant solution a numerical solution is derived in which the eddy viscosity varies across the jet. The results are compared with the corresponding results for a laminar two-dimensional jet.

On nonlinear and linear instability of the Rossby–Haurwitz wave. **Yuri Skiba** (Universidad Nacional Autónoma de M'exico, Mexico) IC/CT592/102

The stability of meteorologically important Rossby–Haurwitz (RH) waves in an ideal incompressible fluid on a rotating sphere is studied. A RH wave of degree n is the sum of a super-rotation flow of H_1 and a polynomial of H_n (H_k is the subspace of homogeneous spherical polynomials of degree k). By a conservation law derived for perturbations, perturbation energy $E(t)$ and enstrophy $\eta(t)$ decrease, remain constant or increase simultaneously. This divides all the perturbations into invariant sets M_-, M_+ and M_0 where $\chi(t) - n(n+1)$ is negative, positive or zero, respectively, and $\chi(t) = \eta(t)/E(t)$ is the perturbation spectral number. Also, M_0 is divided in invariant sets H_n and $M_0 - H_n$. Subspace H_n of neutral perturbations is used as the zero class to introduce a factor space and factor norm of perturbations. The sum of the energy and factor norms is a good norm in the instability study, since the energy norm controls the perturbation part of H_n, and the factor norm -

the perturbation part orthogonal to H_n. It is shown that any RH wave of H_1 is Liapunov, and hence, linearly stable, while any non-zonal RH wave of $H_1 + H_n$ where $n > 1$ is Liapunov unstable to perturbations of M_-. The instability mechanism has nothing in common with Poincare instability being identical with that of a periodic solution to nonlinear pendulum. It is proved that $\chi(t) = n(n+1)$ is the necessary condition for exponential instability (an unstable mode belongs to $M_0 - H_n$). The maximum growth rate of unstable modes is estimated, and the orthogonality of an unstable mode to the RH wave is shown both in the inner product of square integrable functions and in the energy inner product.

Generalized analytic functions in 3D Stokes flows. **Michael Zabarankin** (Stevens Institute of Technology, USA) IC/CT4463/103

A class of generalized analytic functions, defined by a special case of the Carleman system that arises in 3D asymmetric problems of hydrodynamics of Stokes flows, stationary electromagnetic fields in conductive materials, etc., has been considered. Hilbert formulas, establishing relationships between the real and imaginary parts of a generalized analytic function from this class, have been derived for the domains exterior to the contour of spindle, lens, bi-spheres and torus in the meridional cross-section plane. This special case of the Carleman system has been reduced to a second-order difference equation with respect to either the coefficients in series or densities in integral representations of the real and imaginary parts. For spindle and lens, the equation has been solved in the framework of Riemann boundary-value problems in the class of meromorphic functions. For torus, the equation has been solved by means of the Fourier transform, while for bi-spheres, it has been solved by an algebraic method. As examples, analytical expressions for the pressure in the problems of the 3D axially symmetric Stokes flows about rigid spindle-shaped body, lens-shaped body, bi-spheres and torus have been derived based on the corresponding Hilbert formulas.

Non-degeneracy, from the prospect of wave–wave regular interactions of a gas-dynamic type. **Liviu Florin Dinu** (Institute of Mathematics of the Romanian Academy), Marina Ileana Dinu (Polytechnical University of Bucharest, Romania) IC/CT2483/104

An analogue of the genuinely nonlinear character of a one-dimensional simple wave solution is identified and essentially used in the construction of some multidimensional extensions (simple waves solutions, regular interactions of simple waves solutions). A class of exact multidimensional gasdynamic solutions is constructed whose interactive elements are regular.
A *parallel* is constructed between Burnat's algebraic approach (which uses a *dual* connection between the hodograph and physical characteristic details) and Martin's differential approach (centered on a Monge-Ampère type representation) regarding their contribution to describing some nondegenerate gas-dynamic (one-dimensional, multi-dimensional) regular interaction solutions. Some specific aspects of the multidimensional algebraic description are beforehand identified and classified with an admissibility criterion selecting a *genuinely nonlinear* type where other (hybrid) types are formally possible.

Influence of double stratification on MHD free convection with Soret and Dufour effects in a Darcian porous media. **Shyam Tak** (Jai Narain Vyas University, India) IC/CT3907/100

Abstract
The heat and mass transfer characteristics of natural convection about a vertical surface embedded in a doubly stratified saturated porous medium subjected to a magnetic field is studied, taking into account the Dufour and Soret effects. It is found that the similarity solution exists for the case of uniform surface heat and mass flux conditions when the thermal and solutal stratification of the medium are assumed to have power function of x. The resulting set of ordinary coupled nonlinear differential equations is solved numerically using shooting technique. Dimensionless velocity, temperature and concentration profiles are presented graphically and Nusselt and Sherwood numbers are tabulated for various values of the involved parameters. It is observed that the velocity, temperature and concentration profiles for thermal and solutal stratified ambient fluid- porous medium are, in general, smaller than those for the isothermal and iso-solutal ambient fluid-porous medium.

Convection problems in magnetic fluids. **Purna Kaloni** (University of Windsor, Canada) IC/CT3423/107

Magnetic fluids are colloidal suspensions of ferromagnetic nano particles in a nonmagnetic carrier fluid.Each particle has a permanent magnetic dipole moment 'm' but due to thermal agitation the suspension has no net magnetization in the absence of an external field.Depending upon the size of the particles,their concentration and the consideration of rotation,a variety of equations have been proposed to describe them. Convective stability problems under a constant magnetic field or a time periodic field in the simpler theories have already been discussed in the literature, with interesting results. Our purpose here is to study these problems in a most general theory,and in both kinds of magnetic fields.

A new stretch–twist–fold model for fast dynamo. **Renzo Ricca** (Università degli Studi di Milano Bicocca, Italy), Francesca Maggioni (Università degli Studi di Milano Bicocca, Italy) IC/CT3142/103

New equations for the Stretch-Twist-Fold (STF) cycle, originally proposed by Vainshtein and Zeldovich (1972) for the generation of fast dynamo of magnetic fields, are presented and applied to a magnetic flux-tube with twist, following Ricca (*Fluid Dyn. Res.* **36**, 2005). Analytical minimization of the magnetic energy functional is made by using curvilinear, orthogonal coordinates and under the mild constraint of circular tube cross-section and uniform twist field distribution. We show that under appropriate kinematics the constrained minimized energy can grow super-exponentially in time, without necessarily involving high twist rates, hence providing a lower bound on the growth of magnetic energy of the system. These results shed new light on possible efficient mechanisms of magnetic field generation and sustainment for astrophysical and laboratory plasmas.

MHD stagnation-point flow of a non-Newtonian fluid . **Fotini Labropulu** (Luther College-University of Regina, Canada) IC/CT2568/103

The unsteady two-dimensional stagnation point flow of the Walters B' fluid impinging on an infinite plate in the presence of a transverse magnetic field is examined and solutions are obtained. It is assumed that the infinite plate at $y = 0$ is making harmonic oscillations in its own plane. A finite difference technique is employed and solutions for small and large frequencies of the oscillations are obtained for various values of the Hartman's number and the Weissenberg number.

Numerical simulation of Darrieus and Savonius wind-turbine aerodynamics. **Dmytro Redchyts** (National Academy of Sciences of Ukraine, Kyiv), Andrei Zinchenko (Dniepropetrovsk, Ukraine), Olexander Prykhodko (Prykhodko, Ukraine) IC/CT4407/103

The report covers the typical aspects of numerical simulating dynamics and aerodynamics of vertical-axis wind turbines, such as selection of initial mathematical model and the model of turbulence, selection of the numerical method, verification of initial mathematical model and testing of the numerical method, post-processing and visualization of results obtained. Presented method is based on the joint solution of the wind turbine rotation equations and the equations for non-stationary incident wind flow. Simultaneous solution of the aerodynamics equations and the equation of rotor spinning relative to fixed axis under the action of the incident airflow and the fixed loading gives the current rotation speed of wind turbine. The algorithm based unsteady Reynolds averaged Navier-Stokes equations (RANS) used for calculation of aerodynamic characteristics. To close the governing equations following turbulence models were used: SA, SARC and SALSA. Solution of governing equations is obtained using the implicit finite-volume numerical algorithms based on artificial compressibility method and multi-block overlapped structured grids. Verification of the CFD algorithms and codes developed is carried out applying the problems on flow in a cavity and around the fixed and rotating cylinders. Comparison of the turbulence models is given for a flow around the NACA 4412 airfoil. Instantaneous streamlines, vorticity fields and hysteresis of the unsteady aerodynamic characteristics are discussed for an oscillating NACA 0015 airfoil. It is shown that SALSA model demonstrates its advantages on massive flow separation and dynamic stall. Results for Darrieus and Savonius rotors with different geometrical characteristics and different number of blades are presented. Physical features of the flow near wind turbine blades, such as boundary layer separation and flow interactions between the blades, are discussed.

A contractive operator solution of an airfoil design inverse problem. **Jan Šimák** (Aeronautical Research and Test Institute, Czech Republic), Jaroslav Pelant (Aeronautical Research and Test Institute, Czech Republic) IC/CT4297/106

This paper deals with a numerical method for an airfoil design[1]. The method is intended for design of an airfoil from a given velocity distribution along a mean camber line. The stagnation point has to be in the beginning of the mean camber line. The method is based on searching for a fixed point of a contractive operator. This operator combines an inexact inverse operator and equations describing the flow. We assume a subsonic flow described by a system of Euler equations which is solved by an implicit finite volume method. Newton method is applied to the solution of the nonlinear system. The resulting system of linear algebraic equations is solved by GMRES method, the Jacobian-free version is described. The inexact inverse operator constructs a middle curve function and a thickness function with respect to the given velocity distribution. In addition to the velocity distribution the velocity in infinity is given. The angle of attack is determined so that the stagnation point is in a specific position. Successful numerical results are presented.

Non-equilibrium gas–liquid transition model. **Bronislav Librovich** (University of Strathclyde, UK), Andrew Nowakowski (University of Sheffield, UK), Savvas Tassou (Brunel University, UK), Issa Chaer (Brunel University, UK) IC/CT3047/107

A new rigorous mathematical model for evaporation/condensation, including boiling, has been proposed. A problem of phase transition and in particular evaporation/condensation is one of the most acute problems of modern technology with numerous applications in industry, such as: in refrigeration, distillation in chemical industry. It is very common to use equilibrium evaporation model, which assumes that concentrations of species in the gas phase is always at saturated condition. Such kind of approach can lead to significant errors, resulting in negative concentrations in complex computer simulations. In this work two analytical solution of simplified differential-algebraic system have been obtained. One of them was deduced using assumption that the process is isothermal and gas volume fraction is constant. In the second solution the assumption about gas volume fraction has been removed. The code for numerical solution of differential-algebraic system, using conservative scheme, has been developed. It was designed to solve both systems of equations with boiling and without. Numerical calculations of ammonia-water system with various initial conditions, which correspond to evaporation and/or condensation of both components, have been performed. It has been shown that, although system quickly evolves to quasi equilibrium state (the differences between current and equilibrium concentrations are small) it is necessary to use non-equilibrium evaporation model, to calculate accurately evaporation/condensation rates, and consequently all other dependent variables.

Application of high-performance solvers for multiphase flow calculations. **Andrei Zinchenko** (Dniepropetrovsk, Ukraine) IC/CT4126/106

Calculations of heat and mass transfer in heterogeneous media require significant computational efforts in comparison with similar single-phase flows. From the other hand numerical algorithms for such problems are suitable for effective parallelization includes two stages. First of all each phase could be computed separately within one iteration due to explicit form of gas-particle interaction terms. Also we can use the parallelization techniques developed for single-phase flows when computing each phase.

Basing on these ideas the parallelization techniques such as multigrid algorithms, high order difference schemes using flux vector splitting, tracer methods for discrete phase were implemented in applied program package. Well-known and author's developed difference schemes implementation such as TVD-like and compact high order discretizations on the structured block grids were developed.

The problem of interaction of shock waves with gas-particle boundary layer on curvilinear profiles was solved on cluster of personal computers connected with Fast Ethernet network. The particles volume fraction and diameter influence to the

flow separation in interaction zone was investigated. The impact of heating and cooling the surface on boundary layer flow was computed also. Calculation shows above linear acceleration of calculating speed for large scale grids.

Implementing algorithms in the integrated program packages simplifies developing and testing new methods and schemes in both sequential and parallel versions.

The evolution of a viscous two-fluid flow down an inclined plane. **Jürgen Socolowsky** (FH Brandenburg, Germany) IC/CT3940/101

A model describing the unsteady motion of two viscous incompressible fluids down an inclined plane is considered. Both fluids are flowing jointly. At their contact surface and at the free surface we are given the usual free boundary conditions. Thus, the mathematical model represents a non-stationary free boundary value problem for the Navier-Stokes equations. The problem is two-dimensional and it describes the flow regime on some part of different coating devices in Mechanical Engineering. The complete problem is linearized over the steady-state solution. For small initial perturbations the existence of a unique solution, local in time, to the full problem can be shown.

Free-surface film flow over topography under electric fields. **Dmitri Tseluiko** (University of East Anglia, UK) IC/CT4372/101

We investigate a two-dimensional gravity-driven flow of a perfectly conducting viscous liquid down an inclined topographical feature in the presence of a normal electric field. Our interest lies in predicting the free-surface shape of the liquid, particularly the dependence of it on an electric field. Long-wave asymptotic analysis is used to derive a non-linear evolution equation for the interface. We analyse steady-state solutions for flows into a trench and over a mound of a very wide aspect ratio. The sharp-edged walls are approximated by hyperbolic tangent functions and the dependence of the solutions on the parameter that controls the steepness of the walls is analysed. In the absence of an electric field the solution develops a capillary ridge above a downward step and a slight depression in front of an upward step. It is shown that increasing the electric field can completely eliminate the capillary ridge whilst introducing a slight depression right after the downward step, and the film is pulled away from the step. For upward steps the behaviour is opposite Ű the depression in front of an upward step can be completely eliminated by an electric field, while a slight ridge is formed right above the step, and the film is pulled towards the step. The results are corroborated by fully non-linear boundary integral calculations for Stokes flow. The work was done in colloboration with M. Blyth, J.-M. Vanden-Broeck, D. T. Papageorgiou.

Impulsive displacement of liquid in a pipe. **Gerald Kleinstein** (Northeastern University, USA) IC/CT4411/103

We consider the motion of a liquid, originally at rest in a long circular pipe, which is being displaced by another liquid. The purpose of this paper is to show that the displacement problem can be solved by an inviscid analysis, and to establish the displacement time; the time it takes to completely displace the liquid originally at rest in the pipe. As shown by Kleinstein (1988), under impulsive conditions an irrotational initial state may exist but cannot persist; the irrotational motion of the fluid must transition into a viscous motion consistent with the second law of thermodynamics. It is anticipated that in the present problem, due to its impulsive nature, an essentially "inviscid window" may exist for the initial motion. Assuming the time scale of the liquid displacement problem falls primarily within this inviscid window, the solution of the problem could proceed by an inviscid analysis. To test this hypothesis we consider the model of a liquid displaced by the same liquid for which an exact solution of the Navier-Stokes equations exists. Analyzing this model we obtain that the displacement time is essentially inviscid with a small viscous correction of the order of $(l/d)R_p^{-1}$ where R_p is a Reynolds number based on the pressure difference, and l/d is the ratio of length to diameter of the pipe. As additional support for the application of an inviscid analysis to the two liquid problem we show that at the displacement time the viscous layer next to the wall is very thin, it is also of the order of $(l/d)R_p^{-1}$, that the velocity profile, with the exception of the sharp drop near the wall to satisfy the no-slip condition, is essentially flat; and, that the liquid-liquid interface consists of a cylindrical shell, anchored at the ring $x(a,0)=0$, which makes a steep angle with the wall, and at $x=l$ it is cut by essentially a flat surface. We accept these results from the single liquid model, together with the assumption that the viscous correction remains essentially of the same order, as justification for the application of an inviscid analysis to the two liquid problem. Using a control volume analysis, we obtain two coupled ordinary differential equations for the motion of the interface. Combining these two equations results in a single non-linear ordinarry differential equation for the position of the interface for which a closed form solution is derived. We show that the lower the density of the displacing liquid as compared with the density of the displaced liquid, the shorter the displacement time is. In particular, for a horizontal pipe, at the limit when the ratio ρ_A/ρ_B approaches zero, we obtain an explicit expression for the displacement time in the formula, $t_D = l\{(\pi/2)[\rho_B/(p_A-p_B)]\}^{1/2}$ as compared with $t_D = l[2\rho/(p_A-p_B)]^{1/2}$ for the case when $\rho_A=\rho_B$.

Breakup of finite fluid films. **Lou Kondic** (New Jersey Institute of Technology, USA), Javier Diez (UNICEN de Buenos Aires, Argentina) IC/CT4508/108

We study the breakup process of thin fluid films that partially wet a solid surface. Using long-wave (lubrication) approximation, we formulate a nonlinear partial differential equation governing the evolution of the film thickness. This equation includes the effects of capillarity, gravity, and additional conjoining/disjoining pressure term to account for intermolecular forces. We perform standard linear stability analysis of an infinite flat film, and identify the corresponding stable, unstable and metastable regions. Within this framework, we analyze the evolution of a semi-infinite film. The numerical simulations show that for long and thin films, the dewetting fronts of the film generate a pearling process involving successive formation of ridges at the film ends and consecutive pinch-off behind these ridges. On the other hand, for shorter and thicker films, the evolution ends up by forming a single drop. The time evolution as well as the final drops pattern shows a competition between the dewetting mechanisms caused by nucleation and by free surface instability. We find that precise computations, requiring quadrupole precision of computer arithmetic, are often needed to avoid spurious results.

IC/CTS4826/10: Turbulence and transition.

Organiser: Nikolai Kornev (Universität Rostock, Germany)

Turbulent–laminar patterns in plane Couette flow. **Laurette Tuckerman** (LIMSI, France), Dwight Barkley (University of Warwick, UK) IC/CT3187/102

Recent experiments by Prigent and Dauchot have shown that the remarkable spiral turbulence state of Taylor-Couette flow also occurs in plane Couette flow. In both cases, a pattern of alternating turbulent and laminar bands appears at a well-defined Reynolds number. The pattern is tilted with respect to the streamwise (or azimuthal) direction and its wavelength is much larger than the gap; the angle and wavelength depend systematically on Reynolds number. We have numerically simulated these turbulent-laminar patterns for plane Couette flow. In our computational approach, we replace the very large lateral dimensions of the experiment by a narrow and periodically repeating rectangle which is tilted with respect to the streamwise direction. In this way we determine which angles and lengths support turbulent bands. Our computations show a rich variety of turbulent-laminar patterns as the angle and Reynolds number are varied, including spatio-temporal intermittency, branching and travelling states, and localized states analogous to spots. A quantitative analysis of the mean flow of a regular turbulent-laminar pattern reveals that the flow in the quasi-laminar region represents a non-trivial balance between the viscous and advective forces (unlike ordinary laminar Couette flow, in which both forces are zero). Surprisingly, the mean flow and turbulent forces over the entire domain is exactly centro-symmetric and consists of only three trigonometric functions.

Synthesis of artificial turbulent fields with prescribed second-order statistics using the random-spot method. **Nikolai Kornev** (Universität Rostock, Germany), Hannes Kröger (Universität Rostock, Germany), Egon Hassel (Universität Rostock, Germany) IC/CT3362/106

The synthesis of artificial turbulent fields with prescribed statistical properties is an important problem for specification of inlet conditions in LES and DNS simulations.

The starting point of our novel method is the concept of a turbulent flow as a motion of turbulent spots arising at random positions at random times. Each random spot has an inner distribution of velocity which is found from the condition that the statistical properties of the artificial turbulent field are equal to the prescribed ones. In the case of a homogeneous turbulent field we found an analytical solution for the inner distribution provided the autocorrelation functions $\rho(\eta,0,0)$, $\rho(0,\eta,0)$ and $\rho(0,0,\eta)$ (or the corresponding one dimensional energy spectra) and r.m.s of fluctuations are known. In the case of inhomogeneous turbulent fields the solution can be obtained from numerical solution of an integral equation derived from the definition of the correlation function (see Kornev, N. and Hassel, E., 2006, Method of random spots for generation of synthetic turbulent fields with prescribed autocorrelation functions, Commun. Numer. Meth. in Engng, **DOI**:10.1002/cnm.880.).

The field of velocity fluctuations is then conditioned and transformed so that the one-point cross correlations between different velocity components (Reynolds stresses) are taken into account. We propose the transformation which allows to take the Reynolds stresses into acount and doesn't disturb the two-point statistics. A simplified version of the method is developed to generate the velocity field with prescribed integral lengths.

The method is implemented in the software package OpenFoam and used for LES and DNS simulations. The method allows to generate velocity fields with prescribed spatial integral length scales, integral time scales, two-point spatial and one point temporal autocorrelations, as well as one-point cross correlations between fluctuation components. The method has two important advantages in comparison with the other methods capable to generate fields with prescribed two-point statistics. They are the grid independency and simple analytical solutions for the homogeneous case.

Using divergence-free and curl-free wavelets for the simulation of turbulent flows. **Valérie Perrier** (Université Grenoble I, France) IC/CT4086/106

The prediction of fully-developed turbulent flows represents an extremely challenging field of research in scientific computing. The *Direct Numerical Simulation* (DNS) of turbulence requires the integration in time of the full nonlinear Navier–Stokes equations; that is, the computation of all scales of motion.

In that context, wavelet bases provide a decomposition of the solution allowing to represent the intermittent spatial structure of turbulent flows with only few degrees of freedom. For incompressible flows and the Stokes problem, an interesting approach first considered by K. Urban[5], was to use the *divergence-free wavelet bases* originally designed by P.G. Lemarié-Rieusset[4].

In the present talk, we investigate the use of divergence-free wavelets for the simulation of turbulent flows. First we present the divergence-free and curl-free vector wavelets, with their algorithmic implementations in 2D and 3D, leading to fast algorithms (in $\mathrm{O}(N)$ operations where N is the number of grid points)[3]. Then we define an iterative procedure to compute the Helmholtz decomposition of any compressible field, in a wavelet formulation[2]. These ingredients allow us to derive a numerical method for the Navier–Stokes equations, based on divergence-free wavelets. Finally we present numerical tests in 2D to validate the approach[1].

This is work done in collaboration with E. Deriaz.

The multi-spectral decimation scheme for turbulence simulations. **Malcolm Roberts** (University of Alberta, Canada), John Bowman (University of Alberta, Canada) IC/CT3201/106

Shell models of the Gledzer–Ohkitani–Yamada (GOY) type can provide an excellent testbed for new ideas and methods for two- and three-dimensional turbulence. We review some results for Navier–Stokes turbulence and compare with results for shell models. We introduce a *multi-spectral* decimation scheme for high-Reynolds number turbulence simulations.

The nonlinear coupling coefficients on the coarse grid are calculated with a modification of the method of spectral reduction [Bowman, Shadwick, and Morrison, *Phys. Rev. Lett.* **83**, 5491 (1999)]. This decimation scheme exploits the continuity of moments of the underlying probability distribution function to replace neighbouring shells by a reduced number of representative shells with enhanced couplings. The projection and prolongation operators between the grids are designed to conserve energy.

We demonstrate how this multi-spectral scheme might be used to derive a reliable dynamic subgrid model for turbulence.

Regular reflection up to the transition point. **Volker Elling** (Brown University, USA) IC/CT4434/104

Reflection of a weak shock from a solid wedge is a classical problem in gas dynamics studied by Ernst Mach and John von Neumann. There are several possible flow patterns, depending on parameters like wedge sharpness and shock strength. For sufficiently blunt wedges, *regular reflection*, the qualitatively simplest pattern, is observed; as the wedge becomes sharper either *simple*, *double* or *complex Mach reflection* emerge. It is not clear when the transition between regular and Mach reflections occurs. Several criteria have been proposed; it has has even been suggested that there may be bistable flows where regular and Mach reflection are both possible and a change of type can arise from a perturbation. Experimental and numerical evidence is not quite conclusive because physical and numerical boundary layers and other phenomena can blur the picture; for example they can generate spurious Mach stems in a case where regular reflection is observed in perfectly inviscid flow.

Recently, Chen and Feldman have succeeded in constructing regular reflection as an *exact* solution, for compressible potential flow with wedge angle close to $180°$. Elling and Liu independently found different techniques of constructing exact solutions of potential flow and applied it to the classical problem of weak vs. strong shock waves in supersonic flow onto wedges.

In the present work we adapt the techniques of Elling and Liu to show that they are capable of solving regular reflection as well. We demonstrate that the *sonic criterion* is the correct criterion for transition from regular to Mach reflection. For some upstream Mach numbers and sufficiently large γ, including the important $\gamma = 5/3$, we construct exact solutions up to the transition point.

Turbulence simulation using rapid distortion theory. **Mosa Chaisi** (National University of Lesotho) IC/CT4805/106

A fairly simple method of simulating a turbulent domain of a fluid body is demonstrated; which is also fairly inexpensive in terms of computing resources needed to carry it out. The underlying theory employed in dealing with the Navier-Stokes (N-S) equations is what is referred to as Rapid Distortion Theory - linearised N-S equations. Amongst the many physical scenarios where this can be useful, momentum exchange across a gas-liquid interfaces, turbulent mixing and surface renewal are explored with the help of flow visualization in the form of vector plots, flow animation and particle tracking techniques.

A mesh adaptation for non-stationary problems. **Jiří Felcman** (Univerzita Karlova, Czech Republic), Petr Kubera (Purkyne University, Czech Republic) IC/CT4249/106

The subject-matter of this paper is the numerical simulation of the multidimensional inviscid compressible transonic gas flow. An adaptive mesh is constructed in the framework of the ADER higher order cell-centred finite volume scheme. An anisotropic mesh adaptation strategy is followed by a recovery of the approximate solution on the new mesh. The main feature of the proposed method is to keep the mass conservation of the numerical solution at each adaptation step. This allows the solution of non-stationary problems. The geometric conservation law is employed. The numerical solution for the case of a non-stationary discontinuity wave is presented. The algorithm consists of three basic sections at each time step: the time evolution of the numerical solution, the mesh adaptation and the recomputing of the numerical solution from the mesh before the adaptation to the mesh after the adaptation. In one time step the finite volume scheme is evaluated twice. Firstly for the prediction how to adapt the mesh, further for the update of the numerical solution itself. The two-dimensional numerical example employing the described higher-order method with proposed mesh adaptation is presented. The results from [1,2] are further extended.

Non-reflecting boundary conditions for compressible Euler and Navier–Stokes equations in the finite-volume method. **Martin Kyncl** (Aeronautical Research and Test Institute, Czech Republic), Jaroslav Pelant (Aeronautical Research and Test Institute, Czech Republic), Jiří Felcman (Univerzita Karlova, Czech Republic) IC/CT4296/106

The paper is concerned with the numerical implementation of the inlet and outlet boundary conditions in the finite volume method for the solution of the 3D Euler and Navier-Stokes equations. The explicit time marching procedure is described. The classical Riemann problem is modified for physically relevant boundary conditions with the aim to keep conservation laws. This technique was used in [1]. The left hand right initial condition in the Riemann problem is replaced by the suitable one-sided boundary condition. This results in the acceleration of the numerical method itself. On the inlet the pressure and the density and the angle of attack or velocity vector and the entropy are prescribed. On the outlet the pressure or normal component of the velocity or temperature or mass flow are investigated in such a way to obtain the unique solution of the modified Riemann problem. Various combinations of inlet and outlet boundary conditions are investigated. This results in the sufficiently precise approximation of real flow boundary conditions. Numerical examples illustrating the usefulness of the proposed approach for cascade flow will be presented. Another numerical example was shown in [2]. This work was supported by the Grant MSM 0001066902 of the Ministry of Education of the Czech Republic. The authors acknowledge this support.

Recent work on particle simulations. **Robert Krasny** (University of Michigan, Ann Arbor, USA) IC/CT3217/010

This talk will give an overview of recent work on particle simulations by the speaker and his collaborators. The approach taken here uses adaptive particle insertion, kernel smoothing, and a hierarchical treecode for regularized particle interactions. Applications in fluid, plasma, and molecular dynamics will be discussed. Work done in collaboration with Lyudmyla Barannyk, Hualong Feng, and Peijun Li (Michigan), Andrew Christlieb (Michigan State), Ben Sonday (Princeton), Leon Kaganovskiy (New College of Florida), and Hans Johnston (Amherst). Supported by the U.S. AFOSR and NSF.

Clustering of point vortices in a periodic box. **Makoto Umeki** (University of Tokyo, Japan) IC/CT4221/103

Motions of point vortices with periodic boundary conditions are studied by using Weierstrass zeta functions. We observe remarkable scattering and recoupling of vortex pairs when the vortex density is large. Clustering of point vortices with various initial conditions is quantitated with the L function which is used in point process theory in spatial ecology. Clustering in the initial conditions like an infinite row or checkered patterns is shown to persist during the numerical simulation.

Incompressible Navier–Stokes equation solvers based on lattice-Boltzmann relaxation systems. **Mapundi Banda** (University of KwaZulu-Natal, South Africa) IC/CT680/106

In this talk some recent numerical results based on discrete-velocity relaxation systems will be presented. Discrete-velocity equations are derived from continuous Boltzmann-type equations with appropriate approximations suitable for incompressible flows. A relaxation system is derived by taking moments of the discrete-velocity equations. Higher-order numerical discretizations of the relaxation system give higher-order discretizations of fluid flow equations. This approach is also extended to turbulent flows using Large-Eddy Simulation as well as thermal flows. The schemes are tested by solving a collection of examples. In particular the developed methods demonstrate potential as tools for Large Eddy Simulation and flow with Radiative Heat Transfer.

Higher-order semi-implicit discontinuous Galerkin finite-element method for the solution of the compressible Navier–Stokes equations. **Vít Dolejší** (Univerzita Karlova, Czech Republic) IC/CT3457/104

We deal with a numerical solution of the compressible Navier–Stokes equations with the aid of higher order schemes. We employ a combination of the discontinuous Galerkin finite element method for the space semi-discretization and a backward difference formula for the time discretization. Moreover, using a linearization of inviscid as well as viscous fluxes and applying a suitable explicit extrapolation for nonlinear terms we have to solve only a linear algebraic problem at each time step. Then we obtain an efficient numerical scheme which is almost unconditionaly stable and has a higher degree of approximation with respect to the space and time coordinates. We discuss some aspects of a stabilization, boundary conditions and an implementation. Several numerical examples are presented.

Modeling of non-equilibrium phenomena in multiphase flow in porous media using stochastic particles. **Manav Tyagi** (ETH Zürich, Switzerland), Patrick Jenny (ETH Zürich, Switzerland), Hamdi Tchelepi (Stanford University, USA) IC/CT2651/100

Recently, we developed a stochastic particle method (SPM) for modeling multiphase flow in porous media (Tyagi et al., GAMM 2006, Berlin and Tyagi et al., CMWR-XVI 2006, Copenhagen). A Lagrangian viewpoint is adopted, in which a particle belongs to a specific phase. Saturation of a phase is the ensemble or spatial (local) average of the particles belonging to that phase. We showed how one recovers the macroscopic Darcy scale transport equations by moving the particles with the appropriate rules. Such a frame-work allows an alternative (and in some cases more natural) modeling approach of multiphase flow in porous media and provides a consistent link between small and large scales. The method is particularly suited for modeling reactive transport involving non-equilibrium phenomena that are difficult to describe in a deterministic Eulerian framework.
In this work, we show how the SPM can be used to model non-equilibrium effects due saturation fluctuations at the pore scales. This experienced fine scale saturation is not resolved and is a stochastic particle property. For illustration purpose we consider a simple model in which the experienced saturation relaxes to the ensemble saturation according to a linear relaxation equation. In the limit of zero relaxation time, the experienced saturation becomes equal to ensemble saturation. We also derive a transport equation for the probability density function (PDF) of experienced saturation and obtain Eulerian equations for the mean experienced and ensemble saturations. Opposed to the SPM, the Eulerian system of equations is unclosed, and one needs to know either the full joint PDF or has to do additional modeling. A similar approach could be applied for modeling nonlinear chemical reactions by assigning a composition vector to each particle.

Numerical solutions to the dual-phase-lag problem heated by short-pulsed lasers in nano-scale metals. **Alaeddin Malek** (Tarbiat Modares University, Iran) IC/CT756/107

The modified Fourier's law incorporating with the conservation of energy leads to hyperbolic heat conduction equation. Although the HHCE can explain many metal termal behaviors, it also introduces some physically impossible solutions. Instead the dual-phase lag model is more general and allows either the temperature gradient to precede the heat flux or the heat flux to precede the temperature gradient. Mathematically, the DPL model contains a third-order mixed derivative with respect to time, in which makes it different from the traditional heat transfer problem. Both one layer and multilayered structure within the framework of DPL heat conduction model is studied numerically by finite difference, spectral method and latice Boltzman method. Numerical results are presented.

Rayleigh–Bénard convection in a dielectric liquid: time-periodic body force. **Annamma Abraham** (R.V. College of Engineering, Bangalore, India) IC/CT766/106

Exploration of effective mechanisms of controlling convection in dielectric fluids is incessantly going on and has multifarious applications. An important class of natural convection problems is concerned with the difficulty in avoiding convection in the earth's gravitational field even when the basic temperature gradient is uniform and interfacial instabilities can be ignored. In the case of natural or simulated microgravity studies, time-dependent acceleration of sufficient amplitude due

to maneuvers and inherent mechanical vibrations lead to convection. This is referred to as the g-jitter effect. Time-periodic Body Force (TBF) is an externally modulated control of internal convection and may be realized by vertically oscillating a fluid layer in a constant gravitational field. Problems such as these have relevance in crystal growth in extra-terrestrial environment and attempted laboratory simulations of the same. Benjamin and Ursell (1954) examined the effect of TBF on the existence of standing waves on the free surface of a liquid in a vessel. Gresho and Sani (1970) studied the effects of TBF on the stability of a heated fluid layer. The stability of viscoelastic fluids in a modulated gravitational field was investigated by Yang (1997). Recently Siddheshwar and Pranesh (1999, 2000) examined the effect of g-jitter for weak electrically conducting and electrically conducting micropolar fluids.We investigate the effect of small amplitude TBF on the onset of convection in a horizontal layer of dielectric fluid using the Venezian method [1969]. A linear stability analysis is performed. The results obtained are based on the assumption that the amplitude of TBF is small. When $\omega < 1$ (i.e., the period of TBF is large) the TBF affects the entire volume of fluid and hence the disturbances grow large. On the other hand, the effect of TBF disappears for large frequencies. This is due to the fact that the buoyancy force takes a mean value leading to the equilibrium state of the non-TBF case. In the TBF problem R_{2c} is a crucial quantity which determines whether TBF leads to sub-critical instability or not. The results of the study indicate that TBF or g-jitter leads to delayed convection Also for large frequencies the effect of TBF disappears.

Stability of flow past cylinder cascade. **Venkata Boppana** (University of Manchester, UK), Jitesh Gajjar (University of Manchester, UK) IC/CT1748/106

The primary motivation for the current work is to develop suitable techniques for studying the global instability of separation bubbles such as those occurring in the flow past a row of circular cylinders placed in a uniform stream or in the supersonic flow past a compression ramp. In many previous studies of the instability of separation bubbles, the basic flow is taken to be locally parallel and this is used as input into the stability analysis. Mathematically this is only appropriate when the disturbance wavelength is small compared to the distance over which the flow develops and this is not always the case. Nevertheless, in many studies conclusions stemming from such local analyses are extrapolated to generate conclusions about the global instability of the flow. This of course raises questions about the credibility of such results.

In the current work we have extended the methods used to compute the steady flow past a cascade of circular cylinders to study the instability of these flows by using a new numerical technique, which is a high-order finite difference in one direction and Chebychev collocation in the other direction. Before implementing this numerical method, a number of test cases have been used for validation. One such test case is the flow in a lid-driven cavity where the global instability frequencies are found to correlate closely with temporal simulations of the linearised unsteady equations using forced disturbances. This led us to extend our techniques to study the instability of the flow in a cylinder cascade.

Numerical experiments were carried out on various grid sizes to check the convergence of critical parameters causing instability. The study also involved the computations with different locations of downstream boundary and varying blockage in order to understand their effect on critical Reynolds number (Re_c) and the associated Strouhal number (St_c). It is found that the primary instability in the wake for flow past cylinder is found to be due to a Hopf bifurcation and the values of Re_c and St_c are found to be 48.8 and 0.11806. It is also observed from the results that the blockage is significant in determining when the flow loses stability.

An embedding method for simulation of immobilized enzyme kinetics and transport within sessile hydrogel drops. **Ali Nadim** (Claremont Graduate University, USA), Chao-Jen Wong (Claremont Graduate University, USA) IC/CT3069/107

A newly-developed embedding method for simulating enzyme kinetics and transport occurring within axisymmetric 3D domains is presented. The physical problem is pertinent to gel-pad microarrays for assessment of enzymatic activity. An enzyme is immobilized uniformly within a hydrogel which is spotted onto a solid surface in the form of a sessile drop, taking on a spherical cap shape. An aqueous solution containing substrate flows slowly past the porous drop. The substrate diffuses into the drop and is converted to product with the help of the enzyme. The product accumulates in and diffuses out of the drop and is taken away by the flow. Spatiotemporal distribution of the product, monitored via fluorescence, can be used to quantify the enzyme kinetics. This process is described by a system of nonlinear reaction-diffusion partial differential equations, modeling the diffusive transport and enzymatic reaction. The computational domain contains both the hydrogel drop and the bulk fluid phases. The embedding method is a computational technique that enables the use of finite differences on a regular Cartesian grid for simulation of multiphase problems with complex interfaces/boundaries. It uses a volume-fraction-based approach, similar to the volume-of-fluid (VOF) method, to implement the boundary conditions that must be applied at the interface between the phases. The main advantage of the embedding method is its simplicity, which results in code generation that can be highly optimized. In the present work, we apply the embedding method to the aforementioned two-phase reaction-diffusion problem and validate the results by comparing to a number of exact solutions available in simpler geometries and to results obtained using a finite-volume method on an unstructured body-fitted mesh.

Chocked flows in open capillary channels. **Jörg Klatte** (Universität Bremen, Germany) IC/CT1854/101

Capillary systems provide a passive means to control fluids and are widely used for space craft fuel management. In the present study the forced liquid flow through an open capillary channel under low gravity conditions is investigated.

Due to convective and viscous momentum transport the pressure along the flow path decreases and causes the free surface to bend inwards. Furthermore the free surface has a high tendency to oscillate due to minor flow perturbations. The maximum flow rate is achieved when the free surface collapses and gas ingestion occurs. This critical flow rate depends on channel geometry and liquid properties.

The talk concludes unsteady analytical modeling and numerical computations to calculate pressure, free surface curvature or velocity parameters. The results predict the critical flow rate for different geometries and can be used to avoid greater design margins of capillary systems.

Ultrasound propagation through blood containing microbubbles. **Sarah McBurnie** (University of Oxford, UK), Jon Chapman (University of Oxford, UK) IC/CT4413/103

In some types of diagnostic imaging, microbubbles (or ultrasound contrast agents) are injected into the blood to improve the backscatter from blood tissue in a way that enhances and improves the ultrasonic scan image generated. If an improved model for the acoustic scattering can be derived, then the image generated could be further improved.

Blood containing microbubbles is modelled as a bubbly fluid through which an acoustic wave is travelling. Nonlinear effects due to resonant bubble oscillations and bubble–bubble interactions are examined using asymptotic and homogenisation techniques.

Adaptive simulation of fluid–propagule interaction: application to the settlement of seaweed zygotes. **Sébastien Delaux** (NIWA/University of Canterbury, New Zealand), Stephane Popinet (Nat. Inst. of Water and Atmospheric Research, New Zealand), Craig Stevens (Nat. Inst. of Water and Atmospheric Research, New Zealand) IC/CT4500/105

Many phenomena in nature involve a wide range of scales, some of the small scales being sometimes located in regions of restricted size. The numerical study of a multi-scale flow requires the use of a mesh refined enough to solve the smallest scales. Also, problems involving static or moving solid boundaries necessitate an accurate representation of the solid objects involved. This often means that a fine mesh is needed near the solid boundaries. In these cases, the use of adaptive mesh refinement techniques can be very useful.

Both a wide range of scales and solid boundaries are involved in the modelling of the settlement process of seaweed zygotes. New Zealand intertidal seaweeds reproduce by releasing eggs and sperm to the nearshore environment. Once fertilized, seaweed propagules have to reach a suitable substrate and attach. Very little is known about the processes governing attachment and detachment of these propagules, particularly in turbulent wave-driven coastal waters. A critical part of the attachment/detachment process occurs in the turbulent viscous boundary layer near the substrate.

In order to study numerically this problem, a solid/fluid interaction model is being implemented in the Gerris Flow Solver (http://gfs.sf.net). Gerris solves the 2D/3D incompressible Navier-Stokes equations using a finite volume formulation. Gerris is based on a quadtree/octree mesh, adaptive in space and time.

The spatial and temporal adaptivity of the code will allow us to resolve the small eddies and to follow them without spending too much computer power on the rest of the domain. As we are ultimately aiming at doing some 3D simulations, the adaptivity is crucial.

I will mainly present the numerical work done to develop the solid/fluid interaction model in the Gerris Flow Solver. The methods used to implement and validate this model will be exposed in detail. Applications related to the attachment process of seaweed propagules will be presented.

Evolution of solitary marginal disturbances in baroclinic frontal geostrophic dynamics with dissipation and time-varying background flow. **Edwin Swaters** (University of Alberta, Canada) IC/CT4202/102

The finite amplitude evolution of solitary disturbances in baroclinic frontal geostrophic dynamics in the presence of time-varying background flow and dissipation is shown to be governed by a 2-equation extension of the *unstable* nonlinear Schrödinger (UNS) equation with variable coefficients and forcing. The soliton solution of the unperturbed UNS equation corresponds to a saturated isolated coherent anomaly in the baroclinic instability of surface intensified oceanographic fronts and currents. The adiabatic evolution of the propagating soliton and the uniformly valid first-order perturbation fields are determined using a direct perturbation approach together with phase-averaged conservation relations when both dissipation and time-variability are present. It is shown that the soliton amplitude parameter decays exponentially due to the presence of the dissipation but is unaffected by the time variability in the background flow. On the other hand, the soliton translation velocity is unaffected by the dissipation and evolves only in response to the time variability in the background flow. The adiabatic solution for the induced mean flow exhibits a dissipation-generated "shelf region" in the far field behind the soliton, which is removed by solving the initial-value problem.

Multicloud models for tropical convections and convectively-coupled waves. **Boualem Khouider** (University of Victoria, Canada) IC/CT4059/107

Tropical convection and convectively coupled waves have a big impact on our day to day weather and climate. The so called Madden–Julian or intra-seasonal oscillation is believed to effect many important climate and weather patterns such as El-Niño Southern Oscillation, the Asian and Australian monsoons, and the tropical–extratropical tele-connection patterns. Despite the progress in super-computing, the general circulation models (GCM) used for long-term weather and climate predictions at best perform poorly in representing these important tropical waves. This poor performance is partly due to the multiscale nature of these waves and the strong interactions across time and length scales between the individual clouds and the large-scale circulation.

Idealized models with a crude vertical resolution reduced to one to two vertical baroclinic modes are commonly used for both theoretical and numerical studies. Recent analysis of observational data reveals that three cloud types are involved in tropical convection; shallow-non precipitating cumulus clouds, congestus clouds, and deep convective hot-towers expanding in the upper troposphere into stratiform anvils. We propose a new family of multicloud convective parametrization using three cloud-types. Congestus clouds heat the lower half of the troposphere and cool the upper half, while deep convective clouds heat the entire troposphere. Stratiform clouds on the other hand heat the upper troposphere and cool the lower troposphere through evaporation of rain falling into dry air. The resulting phenomenological model is then analyzed both by linear stability theory and non-linear simulations. It is found that the multicloud models capture many key observed features of convectively coupled waves in the tropics.

This is joint work with Andrew J. Majda (NYU).

IC/CTS4934/10: Numerical methods.

Comparison of different techniques for the study of nonlinear laminar flow between parallel perforated disks. **P A Dinesh** (MSRIT, Bangalore, India), Karthik Adimurthi (M.S.Ramaiah Institute of Technology, India) IC/CT25/106

The equations describing similarity solutions for the flow between infinite parallel perforated disks with equal rates of suction or injection at the interface are analyzed. The nonlinear ODE is found to admit a solution for all Reynolds numner (R) using Leray Schauder degree theory. Uniqueness of solution for small Reynolds number is proved analytically. The nonlinear ODE is then solved computationally using regular perturbation technique, numerical finite difference scheme and Padé approximation. From numerical simulations, it is found that regular perturbation method and numerical finite difference

scheme fail for larger values of R, whereas Padé approximation gives converging solution for all values of R and this solution shows the disappearence of boundary layer as $R \to \infty$, and as a consequence shock is developed. For practical applications, the coefficient of skin friction and pressure distribution are also calculated.

Influence of low Mach numbers on the numerical dissipation of Godunov-type schemes. **Felix Rieper** (TU Cottbus, Germany) IC/CT2274/106

We present a new method for analysing the accuracy problem of first-order upwind schemes for the Euler equations in the low Mach number regime. The analysis makes use of the modified equation approach and, with the new concept of *numerical Reynolds numbers*, allows the classification of Riemann solvers and flux vector splittings into two categories: adequately and excessively dissipative.

Roe's approximate Riemann solver is shown to be of the first category, keeping a balance between physical convection and artificial dissipation for all characteristic waves independent of the Mach number. Further members of this class are HLLC and the original Godunov scheme. Correct flow simulations with an $\mathcal{O}(\mathrm{M}^2)$-pressure field for Mach numbers as low as $\mathrm{M} = 10^{-6}$ confirm the analysis.

HLL is shown to become more and more dissipative for low Mach numbers, leading to highly viscous flow that resembles *Stokes* or *creeping flow* with an $\mathcal{O}(\mathrm{M})$-pressure field. Numerical results verify this analogy. This class of upwind schemes with excessive numerical dissipation is shown to comprise the flux vector splittings of van Leer and Steger–Warming.

A novel pressure decomposition into physically and numerically induced pressure variations explains the different order of magnitudes of pressure fields, observed for the two classes of upwind schemes in this flow regime.

Adaptive least-squares finite-element approximations to transonic-flow problems. **Tsu-Fen Chen** (National Chung Cheng University, Taiwan), Shin-Perng Chang (Toko University, Taiwan) IC/CT4726/010

This work concerns solutions of compressible potential flow problems based on weighted least-squares finite element approximations. The model problem considered is that of the potential flow past a circular cylinder. To capture the transonic flow region, an adaptive algorithm based on mesh redistribution with local mesh refinement and smoothing is developed for suitably weighted least-squares approximations. Numerical results for the model problem are given for both subsonic and transonic cases.

Mixed finite approximation of a coupled reservoir–well-bore problem with heat transfer. **Layal Lizaik** (Université de Pau et des Pays de l'Adour, France), Mohamed Amara (Université de Pau et des Pays de l'Adour, France), Daniela Capatina-Papaghiuc (Université de Pau et des Pays de l'Adour, France) IC/CT2005/025

We are interested in the thermomechanical coupling of a petroleum reservoir with a vertical wellbore, both written in 2D axisymmetric form, in order to interpret recorded temperatures in the wellbore as well as a flowrate history and thus to better characterize the reservoir. The reservoir is assumed to be a monophasic porous medium, described by the Darcy-Forchheimer equation together with a non standard energy balance which includes viscous dissipation and compressibility effects. Concerning the wellbore, which is a compressible fluid medium based on the Navier-Stokes equations, a 1.5D model is derived as a conforming approximation of the 2D axisymmetric one. In order to couple the two models, adequate transmission conditions at the perforations are imposed and next dualized by means of Lagrange multipliers. We obtain, at each time step, a mixed formulation binding together the two formulations of the separated models. Mathematically, its operator is non standard and the uniqueness of the solution is established by means of a generalization of the Babuška-Brezzi theorem. A global solving of the coupled problem is then envisaged. Concerning the spatial discretization, we approximate the heat and mass fluxes by the lowest-order Raviart-Thomas mixed elements, the pressure and the temperature by piecewise constant elements, the fluid's velocity by Q_1 continuous elements while the Lagrange multipliers on the interface are taken piecewise constant. The convective terms are treated by appropriated upwind schemes. A technical analysis of the discrete mixed formulation is carried on and the well-posedness of the problem is proved. This result is used to show the existence of a solution for the continuous coupled problem by a Galerkin method. Numerical tests including real cases as well as a comparison with the results obtained separately by the two models will be presented. This work is supported by TOTAL.

Preconditioners for hydropower plant reservoir flow simulations. **Norberto Mangiavacchi** (Universidade do Estado do Rio de Janeiro, Brazil), Luiz Carvalho (Universidade do Estado do Rio de Janeiro, Brazil), Cassio Soares (Furnas Centrais Elétricas S.A., Brazil), Virginia Costa (Universidade do Estado do Rio de Janeiro, Brazil), Wagner Fortes (Universidade do Estado do Rio de Janeiro, Brazil) IC/CT2534/103

The incompressible Navier–Stokes equations are solved employing Finite Element approximations for the simulation of hydroelectric power generation reservoir flows. We present different approaches for the solution of the coupled velocity-pressure algebraic equations. In the first approach, an approximate block Cholesky factorization is employed, which reduces the problem to the solution of two uncoupled SPD systems, which are solved using the PCG method, with incomplete Cholesky preconditioners. In the second one, the system is solved employing the GMRES method. For this method, several preconditioning strategies are compared. One of the choices of preconditioning is based on the block Cholesky factorization of the uncoupled problem. The preconditioners are implemented using Trilinos and the main code is written in C++, using an Object Oriented approach. For the computational kernels, combinations of optimized sparse and dense BLAS are implemented. Results are discussed.

This work was developed at GESAR Labs (UERJ, Rio de Janeiro, Brazil), with financial support from FURNAS CENTRAIS ELÉTRICAS S.A., CAPES and CNPq.

Variational method in the unified coordinate system. **Guiping Zhao** (IAPCM, Beijing, PR China) IC/CT2089/106

How to establish the equation of the arbitrary parameter h, which is introduced into the fluid dynamic equations in the unified coordinate system, is very important in simulating the multi-material flow. On the interface between the different materials which we are interested in, the h value should be 1 so that we can obtain Lagrange solution. In the unified coordinate system, the h equation is hyperbolic, and h value canŠt be fixed on all boundaries. In this paper, variational method is used to form the elliptic h equation, and the mesh spacing, smoothness, orthogonality and regularity of grid generated are also considered. Some typical examples demonstrate that variation method used in the unified coordinate system is possible, and

the distribution of h can be adjusted by given different boundary conditions, so as to get adaptive meshes for idiographic physical problems.

Key words: Unified coordinate system, h-equation, Variation method, Interface

IC/CTS4831/10: Cavitating flow, porous media, boundary layers and cavity flow.

Re-entrant corner flows of Phan-Thien-Tanner fluids. **Jonathan Evans** (University of Bath, UK) IC/CT4786/103

Steady planar flow of the Phan-Thien-Tanner (PTT) fluid is described for re-entrant corners with angles π/α where $1/2 \leq \alpha < 1$. Local to the corner we consider a class of similarity solutions associated with the inviscid flow equations which arise from the dominance of the upper convective stress derivative in the constitutive equations. These solutions hold in an outer (core flow) region and give stress singularities of $O(r^{-2(1-\alpha)})$ (with r the radial distance from the corner) and a stream function behaviour of $O(r^{n\alpha})$. Here n is a parameter defining distinct solutions within this similarity class. We match such solutions to inner regions at the walls (i.e. wall boundary layers), in which viscometric behaviour is retrieved and which determines $n = 1 + \alpha$. The formulation is carried out using both the Cartesian and natural stress basis and it is implicitly assumed that there are no regions of recirculation at the upstream wall i.e. we consider flow in the absence of a lip vortex. In this situation, a two parameter family of solutions is described for the local asymptotic behaviour of the flow and stress fields. Essential features of the analysis are the matching of the core region to the wall boundary layers, the solution (numerical and asymptotic) of the upstream and downstream boundary layers, together with the explicit determination of the essential singularity possessed by the boundary layer equations at the downstream wall.

Such re-entrant corners arise naturally in planar or axisymmetric contraction flows and are standard problems for the testing of numerical methods. However, the stress singularities that arise pose numerical difficulties, particularly near to and downstream of the corner for a wide class of elastic fluids (the PTT fluid being one such type).

Numerical simulation of non-classical waves for immiscible three-phase flow in heterogeneous porous media. **Eduardo Abreu** (Universidade do Estado do Rio de Janeiro, Brazil) IC/CT616/100

We describe the development of a numerical simulation tool for three-phase immiscible incompressible flow. The porous medium may be heterogeneous, including variable permeability and porosity fields, and general relations for the relative permeability functions may also be used. The latter may lead to the loss of strict hyperbolicity and, thus, to the existence of an elliptic region or an umbilic point for the system of nonlinear hyperbolic conservation laws describing the convective transport of the fluid phases. This numerical procedure has been used to investigate the existence and stability of nonclassical waves (also called transitional or undercompressive waves) in heterogeneous two-dimensional flows, thereby extending previous results for one-dimensional problems. Preliminary results concerning the investigation of gravity effects on three-phase flows will be also presented. Work done in collaboration with: Fred Furtado (UWYO/USA), Dan Marchesin (IMPA/BRAZIL) and Felipe Pereira (UERJ/BRAZIL).

Numerical study of transient natural convection in a cavity with multiple adiabatic blocks. **Durga Charan Dalal** (IIT Guwahati, India), Swapan Pandit (IIT Guwahati, India) IC/CT2947/107

This study deals with the solution of a problem of unsteady natural convection in a thermally driven square enclosure with four adiabatic square blocks placed inside. In this problem, vertical walls are assumed to be adiabatic and horizontal walls are differentially heated where the lower wall is hot and the upper one is cold. A fourth-order accurate compact scheme which is spatially fourth order and temporally second order accurate has been employed on a nonuniform grid to numerically solve the governing equations. A detailed study of transient flow structure and heat transfer in the presence of four adiabatic blocks for different Rayleigh numbers (mainly, ranging from 10^3 to 10^6) has been made.

In order to validate the code, our results have been compared with those of Davis [*Int. J. Numer. Methods Fluids* **3**, 249, 1983] (known as benchmark results) and found an excellent agreement. The numerical results corresponding to the steady state fluid flow and temperature fields at $Ra = 10^3$ show the four symmetrical zones around four blocks. For $Ra = 10^4$ and 10^5, the flow and temperature fields reach their steady-state after some decaying oscillatory transient. Flow and temperature fields for $Ra = 10^6$ or higher, are quite different. [Our study has not yet been fully completed.]

Super-critical withdrawal from a two-layer fluid in a porous medium. **Graeme Hocking** (Murdoch University, Australia) IC/CT4178/101

During withdrawal of oil below gas, or fresh water from above salty in a porous medium, there is a critical flow rate above which both layers begin to flow into the outlet. Numerical calculations of the interface shape (and critical values) indicate that the critical flow value obtained is either much lower than earlier hodograph techniques suggest or is accompanied by a sudden jump in the shape of the dividing boundary.

On analogy of effect of random errors to several stabilizing terms in flow simulations. **Itaru Hataue** (Kanazawa University, Japan) IC/CT1182/106

TThe complicated phenomenon such as flow motions can be simulated easily as if they were open before our eyes actually. However, nobody can confirm whether computed results reliable or not. This is responsible for the strong nonlinearity induced by insertion of random errors. In this paper, we studied the structure of numerical solutions of flow simulations in order to clarify effects of such insertion of random errors. Concretely, we investigate the characteristics of asymptotic numerical solutions which are given by solving incompressible Navier Stokes equations directly. The incompressible Navier-Stokes equations and the continuity equation are solved numerically by using the MAC(Maker-And-Cell) method and implicit temporal scheme. The model adopted in the present study is a flow around a two-dimensional circular cylinder and the Reynolds number is 1500. We must introduce the higher order artificial viscosity terms in order to perform the calculations stably and we get multiple stable asymptotic solutions by selecting the amplitude of the artificial viscosity tems. Though the numerical fourth order artificial viscosity has the stabilizing effect like the physical second order one, the bifurcation processes are different. On the other hand, we studied influences of structure of numerical solutions which are given by solving the Navier-Stokes equations numerically on amplitude of added randomness. Random noises are given by using pseudo-random number. As the result, we found that characteristics of asymptotic solutions change under the condition of insertion of random noises. This phenomenon may relate to the stochastic resonance or the entrainment phenomena. Further-

more, we discussed the analogy of effect of Random errors to several stabilizing terms in flow simulations in the present study. Concretely, we concentrate the dependence of bifurcation processes on the amplitude of fourth order viscosity terms and that of added random errors. It was shown that relatively large random errors stabilize the system and havw the similar effect of stabilizing viscosity terms. Furthermore, dependence of stability of attractors on several types of insertion of random errors is discussed.

Oblique water-wave scattering by a small undulation on a porous sea-bed. **Subash Martha** (IIT Guwahati, India), Swaroop Bora (IIT Guwahati, India) IC/CT429/101

Almost all the existing investigations on the wave reflection and/or transmission problems of porous structures are investigated by assuming horizontal sea-bed. However, in practical coastal engineering, an undulating sea-bed is more likely to be encountered for the interaction with wave motion. The problem of scattering of two dimensional surface water waves by small undulation on a sea-bed of finite depth is considered here assuming the sea-bed to be composed of porous material of specific type. The governing boundary value problem (BVP) is reduced to a simpler BVP for the first order correction of the potential using perturbation analysis which involves a small parameter ϵ present in the representation of the small undulations on the porous sea-bed. Fourier transform method is utilized to obtain the complete solution of the mixed boundary value problem, under the assumption that the undulation of the sea-bed is small enough so that a regular perturbation expansion in terms of a small undulation parameter is applicable. The reflection and transmission coefficients are determined and applied to the case of a patch of sinusoidal undulations on the bed. When the ripple wave number (l) is equal to twice the $x-$component (μ) of the surface wave number, the first order reflection coefficient is found to increase when the bed has more porous effect. When there is no porous effect on the sea-bed it is found that the present results resemble the ones obtained earlier by Davies and Heathershaw (1984) for surface wave propagation over sinusoidally topography. The results are presented in graphical forms. The case of oblique incidence is handled completely.

IC/CTS4932/10: Interior flow, flow about cones.

Application to Noshiro's ventilation system. **Masao Igarashi** (Nihon University, Japan), Yukio Yanagisawa (Nihon University, Japan), Cheng Yen Tsai (Nihon University, Taiwan), Makoto Murofushi (Osaka University, Japan) IC/CT3968/010

Nearly one hundred years ago, in 1910, K. Noshiro invented a buoyancy-driven natural ventilation system which controlled the temperature of a malted rice room called *Koj*' room to be almost constant and contribute to produce high-quality rice-wine called Sake.

He installed two different-length chimneys at the top of the room to control the temperature. The shorter chimney supplies cooler air into the room, on the other hand the longer chimney releases warmer air from the room. The system controlled the temperature of the room adequately, so that the high quality of Sake was produced.

We propose a new buoyancy-driven natural ventilation system which consists of just one chimney. The top of the chimney is not flat, but slope. The slope creates a circulation of heat between the room and outside, that is, the taller side of the chimney releases the warmer air from the room and the shorter side supplies the cooler air into the room. The difference between the taller side of the temperature and the shorter side of the temperature is increasing with decreasing the width of the chimney. However for a very small width, the temperature at the both sides is closed together.

We propose a chimney whose top is angled and show that the chimney makes a natural ventilation. We also consider the effective angle of the chimney to arise the natural ventilation.

Axisymmetric and non-axisymmetric flow modes between rotating coaxial cones. **Christopher Hills** (Dublin Institute of Technology, Ireland) IC/CT2160/105

We consider the slow flow of a fluid contained in the conical cavity formed between two coaxial cones with coincident apices. The fluid is set in motion by the rotation of the conical boundaries or a bounding spherical lid. The Stokes flow is laminar but at higher orders a meridional circulation is induced due to the sloping boundaries. This meridional circulation can exhibit recirculation regions or eddies for determined constraints upon the geometrical and dynamical parameters. The three-dimensional slow flow can thus be exploited in the manufacture of pumps, particularly in the medical sciences, and has implications for the mixing of viscous fluids in this geometry.

Truncated two-cone geometries have been previously studied experimentally but there are relatively few theoretical treatments of the full two conical geometry. Eddies can occur in the cavity of a single fluid filled cone for apex angles less than a critical value, but it is found that the addition of a second cone has a dramatic effect upon this critical angle.

We investigate the presence of eddies due to the dominance of flow components associated with the geometry over forced flow effects. A variety of driving mechanisms is studied where the conical boundaries and spherical lid are allowed to rotate independently with particular attention to the destruction of eddies by shearing and overall rotation. Eddies can also arise due to symmetries of the driving mechanism. We extend our previous analyses by also considering non-axisymmetric flow modes. It is shown that the dominant flow mode is associated with non-zero azimuthal wave numbers and that cascades of eddies can be guaranteed.

Work done in collaboration with O. Hall & A.D. Gilbert, University of Exeter, UK.

Effect of pressure work on free convection flow along a vertical circular cone with suction and variable surface temperature. **Md Abdul Alim** (Bangladesh University of Engineering & Technology) IC/CT781/010

Free convection laminar flow from a vertical circular cone maintained a variable surface temperature with suction and pressure work effects has been investigated. The governing boundary layer equations are transformed into a non-dimensional form and the resulting nonlinear system of partial differential equations are reduced to local non-similarity equations. The governing non-similarity equations are then solved numerically by Implicit finite difference method together with Keller box scheme. Numerical results are presented in terms of velocity and temperature profiles of the fluid as well as the local skin-friction coefficients and the local heat transfer rate for different values of Prandtl number $\Pr$, suction parameter ξ, temperature gradient parameter n and the pressure work parameter $\in$.

Optimal control of flows in moving domains. **Bartosz Protas** (McMaster University, Canada), Wenyuan Liao (McMaster University, Canada), Donn Glander (General Motors Research & Development Center, USA) IC/CT2599/105

This investigation concerns adjoint-based optimization of viscous incompressible flows (the Navier–Stokes problem) coupled with heat conduction involving change of phase (the Stefan problem) and occurring in domains with moving boundaries such as the free and solidification surfaces. This problem is motivated by optimization of advanced welding techniques used in automotive manufacturing, where the goal is to determine an optimal heat input, so as to obtain a desired shape of the weld pool surface upon solidification. This will guarantee good properties of the resulting joint. In order to use a gradient based optimization approach, it is necessary to characterize the sensitivity (i.e., the gradient) of the cost functional with respect to the control (the heat input). This can be done conveniently using suitably-defined adjoint equations. A difficulty in the present problem is that the shape of the domain is also a dependent variable, and both the cost functional and the state variables need to be differentiated with respect to evolution of the domain. This is accomplished using methods of *non-cylindrical* calculus which allows us to derive a perturbation system accounting for domain variability. An adjoint system is derived afterwards which, unlike the forward problem, is defined on a domain with a predetermined evolution in time and also involves ordinary differential equations defined on the domain boundary (*the adjoint transverse system*). In our presentation, after formulating the optimization problem, we will review basic elements of the non-cylindrical calculus and show how it can be used to derive the perturbation system. For the sake of clarity, these derivations will be analyzed using a simpler model problem involving a 1D heat equation in a variable domain. Finally, we will discuss certain computational aspects of numerical solution of such adjoint problems and will present numerical results concerning both the model and the original problem.

IC/CTS4975/10: Special fluids.

Organiser: Mehmet Pakdemirli (Department of mechanical Engineering, Celal Bayar, Turkey)

Solutions of a generalized hyperbolic non-Newtonian fluid flow for special geometries. **Mehmet Pakdemirli** (Department of mechanical Engineering, Celal Bayar, Turkey), Pinar Sari (Celal Bayar University, Turkey), Bekir Solmaz (Celal Bayar University, Turkey) IC/CT1102/103

A generalized hyperbolic non-Newtonian fluid model is considered. The model was successfully applied to some drilling fluids with better performance in relating shear stress and velocity gradient compared to power-law and Hershel-Bulkley model. Special flow geometries namely pipe flow, parallel plate flow and flow between rotating cylinders are treated. For the first two cases, analytical solutions in the form of integrals are presented. The velocity profiles and discharge are calculated by numerically evaluating the integrals. For the flow between rotating cylinders, the differential equation is solved by Runge-Kutta method combined with shooting.

Optimizing the source distribution in fluid mixing. **Jean-Luc Thiffeault** (Imperial College London, UK), Grigorios Pavliotis (Imperial College London, UK) IC/CT2184/107

Consider a passive scalar advected by a velocity field, and assume the concentration of the scalar is continually replenished by a spatial source. For example, we could have a source of heat with hot and cold spots, such that the mean temperature is constant. An obvious question is, which velocity fields are best at homogenizing the concentration field? This is a challenging question, and here we turn it around into a less obvious one: given a velocity field, which source distributions are best mixed by this field? This question is simpler to answer and yet is relevant to real mixing problems. We use a multiscale measure of steady-state mixing efficiency [1,2], similar to the mix-norm [3], and optimize it using a variational approach. We then solve the resulting Euler–Lagrange equation for a simple cellular flow. The optimal source distributions have many gross features that are as expected: they favor fast regions of the flow, and their contours are aligned such that the flow blows hot spots onto cold spots and vice versa. However, the detailed structure varies widely with diffusivity and other problem parameters. Though this is a toy problem, the procedure is easy enough to be adapted to more complex situations.

Large-scale simulation of shock- and detonation-driven fluid-structure interaction phenomena. **Ralf Deiterding** (Oak Ridge National Laboratory, USA) IC/CT3232/105

The impact of shock or detonation waves on solid materials can induce large structural deformations, fracture and fragmentation. Coupled fluid-structure interaction simulations are very challenging, because numerical methods have to cope with complex topology evolutions. We present an approach to coupling that uses a level set function for implicit geometry representation and is particularly robust [1].

The compressible fluid flow is simulated with a high-resolution shock-capturing Cartesian finite volume upwind method in Eulerian coordinates that considers the solid as a moving embedded body based on the current level set information. The structural response is calculated with problem-specific finite element schemes in Lagrangian coordinates. A loosely coupling temporal splitting method is applied to update the boundary's positions and velocities between time steps. The Eulerian finite volume scheme is incorporated into a parallel structured dynamic mesh adaptation algorithm that allows very fine local resolutions to capture the near-body interaction and incoming waves in the fluid at minimal computational costs. As the solid deforms, the level set function storing the distance to the solid surface is updated on-the-fly by a highly efficient auxiliary algorithm that utilizes geometric characteristic reconstruction and scan conversion.

As large-scale, three-dimensional computational examples we consider the deformation of a metal container due to the combustion of a high-energetic solid explosive, the rupture of thin aluminum tubes induced by interior gaseous detonations, and the deformation of copper plates under water hammer. Briefly, the software design and the parallelization of all components for distributed memory computing platforms are sketched.

Direct numerical simulation of turbulent visco-elastic flows: dynamic Karhunen–Loeve analysis. **Antony Beris** (University of Delaware, USA), Gaurab Samanta (University of Delaware, USA) IC/CT4556/103

Polymer-induced turbulent drag reduction has been the subject of intense investigations ever since its accidental discovery by Tomms and Mysels during the Second World War, with important applications, most well known of which is the facilitation of the oil transfer though pipelines, such as in the Alaskan pipeline. Recent developments in numerical methods, and more specifically an exponential mapping for the viscoelastic conformation tensor that allows us to preserve its positive definiteness under all flow conditions exactly, allowed us to obtain accurate and stable simulations up to highly drag reduced (more than 60%) turbulent channel flows of dilute polymer solutions. The most recent data confirm earlier results in our group at lower drag reduction values whereby the primary mechanism for drag reduction is the decreased intensity of the wall eddies which is the result of a significant increase to extensional deformations contributed by the polymer additives, exactly as proposed earlier by Metzner and Lumley. Recent work has been able to more systematically investigate the changes to the flow structure effected due to the polymers, and in particular the coherent structures, using Karhunen-Loeve (K-L) Proper Orthogonal Decomposition (POD) analysis of the data. This demonstrated a dramatic enhancement of the importance of large scale motions with increased viscoelasticity and an equally dramatic decrease in the K-L dimension of the flow (an order of magnitude) as viscoelasticity increases versus similar Newtonian results. Moreover, the time-dependent dynamic analysis of the solution in terms of the K-L modes has confirmed the increased time scales encountered with viscoelasticity and has proven useful towards establishing a better understanding of the turbulent coherent structures and their interrelationships as they have been modified by viscoelasticity.

IC/CTS4830/10: Reactive flows and heat transfer.

Organiser: Ilya Simanovskii (Technion – Israel Institute of Technology)

Finite-element method simulation of rotating disk flow: effect of the transport of a chemical species. **José Pontes** (Universidade Federal do Rio de Janeiro, Brazil), Gustavo dos Anjos (Universidade do Estado do Rio de Janeiro, Brazil), Norberto Mangiavacchi (Universidade do Estado do Rio de Janeiro, Brazil) IC/CT3158/103

We consider the stability of rotating disk flow coupled, through the fluid viscosity, to the mass concentration field of a chemical species. This configuration refers to an electrochemical cell with an working electrode consisting of an iron rotating rod which is dissolved in the electrolyte, a 1 $\mathbf{M}$ $\mathbf{H_2SO_4}$ solution. Polarization curves obtained in such cells present a current instability at the beginning of the region where the current is controlled by the mass transport. The instability appears at a certain value of the applied potential and is suppressed beyond another value. Dissolution of the electrode gives rise to a thin concentration boundary layer, which, together with the potential applied to the electrode, results in an increase in the fluid viscosity and in a decrease in the diffusion coefficient, both affecting the current. This work deals with the question of whether the current instability may originate from an instability of the coupled fields, namely, if the coupling reduces the critical Reynolds number to values comparable to those attained in experimental setups. A phenomenological law is assumed, relating the fluid viscosity to the concentration of a relevant chemical species. Parameters appearing in this law are evaluated on basis of experimental electrochemical data.

The Finite Element Method (FEM) is employed to solve the coupled incompressible Navier-Stokes and chemical species transport equations, using a tetrahedral mesh. A semi-Lagrangian technique is used for the discretization of the material derivatives, and the spatio-temporal discretization is made through the implicit Taylor-Galerkin method,leading to an unconditionally stable scheme, suitable for large Reynolds and CFL numbers. Pressure and velocity are solved using a segregated LU factorization scheme. The resulting symmetric and positive-definite systems are solved by the Preconditioned Conjugate Gradient method. Good numerical stability properties were obtained with the proposed scheme and the results are in agreement with a linear stability analysis of the problem.

The authors acknowledge financial support from the brazilian agency CNPq.

Numerical modeling of the hydrodynamic field coupled to the transport of chemical species through the finite-element method. **Gustavo dos Anjos** (Universidade do Estado do Rio de Janeiro, Brazil), Norberto Mangiavacchi (Universidade do Estado do Rio de Janeiro, Brazil), José Pontes (Universidade Federal do Rio de Janeiro, Brazil), Cassio Soares (Furnas Centrais Elétricas S.A., Brazil) IC/CT3133/101

The simulation of the complex fluid flow and transport in hydro-powerplant reservoirs requires the solution of the Navier-Stokes equations coupled, through the physical properties of the fluid, to the transport equation of chemical species and the energy equation. The purpose of this study is to develop a Finite Element Method for the simulation of the filling of hydropower plant reservoirs, in order to asses the environmental effects of the formation of the reservoirs and analyse possible strategies for remediation.

The domain is discretized employing a Delaunay Tetrahedralization algorithm, to guarantee good properties in the element mesh. Spatial discretization of the diffusion and pressure terms is made through the Galerkin method whereas the substantial derivatives are treated through a semi-Lagrangian technique that presents natural stability. The time discretization is done through a first-order backward Euler implicit scheme. The large systems of coupled linear equations are solved through the discrete projection method based on the LU decomposition, resulting in symmetric positive-definite system matrices. The method proved to be stable at all CFL and Reynolds conditions, not showing spurious oscillations or excessive numerical diffusion even under large Reynolds number conditions.

This work was developed at GESAR Labs, in the State University of Rio de Janeiro, Brazil, under the sponsorship of the brazilian power company FURNAS CENTRAIS ELÉTRICAS S.A., CAPES, and CNPq, from whom the authors acknowledge the support.

Nonlinear convective oscillations in multilayer systems. **Ilya Simanovskii** (Technion – Israel Institute of Technology) IC/CT548/107

During the last few decades, a new scientific direction of investigation, convection in multilayer systems, was developed. Among the modern techniques requiring an investigation of convection in systems with many interfaces are liquid encapsulation crystal growth technique used in space labs missions, droplet-droplet coalescence processes, where Marangoni convection in the interdroplet film can considerably affect the coalescence time during extraction, and others. A scientific interest in such systems is due to the fact that the interfacial convection in multilayer systems is characterized by a variety of physical mechanisms and types of instability (for a review, see A. Nepomnyashchy, I. Simanovskii, J.C. Legros "Interfacial convection in multilayer systems", Springer, New York, 2006).

In the present work some peculiarities of the instabilities in three-layer systems are investigated. It is shown that the oscillatory instability in multilayer systems is much more widespread that in a two-layer one. Direct and indirect interaction of different mechanisms of instability may lead to specific types of oscillations. The nonlinear simulations of the Marangoni convection in a symmetric three-layer system of fluids, 47v2 silicone oil – water – 47v2 silicone oil, have been performed. Different types of oscillatory motions, as well as transitions between nonlinear convective regimes, have been studied.

The joint action of buoyancy and thermocapillary effect on the convection in the three-layer system, air – ethylene glycol – fluorinert FC75, is investigated. The stability diagram on the plane the Grashof number – the Marangoni number, is constructed. It is shown that the region of the Grashof number values, where nonlinear oscillations take place, is bounded both from below, by the mechanical equilibrium, and from above, by the steady state.

Numercial simulations for a fluid in an elastic cylinder with two chambers. **Sunmi Lee** (Konkuk University, Republic of Korea), Eunok Jung (Konkuk University, Republic of Korea) IC/CT742/010

In this work, we construct a new model of valveless pumping for an elastic tube with two chambers. Mathematical modeling and numerical simulations of flows driven by periodic pumping are presented. A periodic compression of the assymmetric part of the soft tube generates a unidirectional flow. Both the amount and the direction of a net flow depend on the frequency and the compression of periodic pumping.

Optimal control on thermo-convective patterns. **Maria Cruz Maria Cruz** (Universidad de Castilla-La Mancha, Spain), Henar Herrero (Universidad de Castilla-La Mancha, Spain), Ana Mancho (Consejo Superior de Investigaciones Científicas, Spain) IC/CT3276/107

We study the optimal control and the linear stability of stationary thermally convected fluid flows induced by a horizontal temperature gradient and driven by the buoyant force. The control is effected through a heat flux on the top boundary. The control problem is formulated as a constrained minimization problem. We establish the first-order necessary condition of optimality from which optimal control can be obtained. The controlled states are calculated numerically and their linear stability is examined. We conclude that these states are strongly stable for situations of efficient reduction of enstrophy. In particular, we find that the pattern is substituted by a stable quasi conductive state.

Evolution equation for the subgrid heat fluxes in a finite-volume formulation. **Ivan Otic** (Forschungszentrum Karlsruhe, Germany) IC/CT4222/106

Large-eddy simulation (LES) of turbulent heat and mass transfer is a numerical approximation where the large scales of motion are supposed to be resolved while the small scales are modeled using a sub-grid scale (SGS) model. One approach for obtaining the SGS models consists in solving evolution equations for the sub-grid stress tensor and the sub-grid heat flux vector. This approach proposed by Deardorf and recently reinvestigated by Fureby, Tabor, Weller and Gosman may considerably improve the predictions at higher Reynolds numbers by minimal increase of computational cost. Definition of the large-scales to be simulated is similar to numerical discretization in that a finite-dimensional representation of an infinite dimensional solution is defined. The mapping to the finite dimensional representation (the filter) can be defined as in common numerical representations such as spectral, finite volume and finite element formulations. Clearly, the unrepresented sub-grid scales and the way they are modeled depend on the formulation used. Finite volume formulation is commonly applied because of its general applicability to flows in complex geometries.
We discuss here a finite volume formulation for a SGS heat flux model. We derive an evolution equation for the sub-grid heat flux vector for an LES filter that is consistent with finite volume representations. This derivation is similar to the derivations by Schumann and Grötzbach for the sub-grid kinetic energy and sub-grid temperature variance, respectively. The resulting equation has following properties:
1) it is consistent with Germano's filtering invariance property
2) there is a molecular term in the equation which does not appear in the equation derived by Deardorf.
This molecular term corresponds to the resolved scales of the heat flux dissipation rate and offers therefore an advantage for modeling and predictions of turbulent heat transfer. Using this equation we develop a differential sub-grid heat flux model. Algebraic SGS models seem to be very promising for engineering computations, as pointed out by Hanjalić. Assuming the small scale local equilibrium this evolution equation is simplified and an algebraic SGS heat flux model is derived.

IC/PP2254/010: **Parametric modulation in the Taylor–Couette ferro-fluid flow.**

Presenter: Jitender Singh (Punjab University, Chandigarh, India)
Co-author: Renu Bajaj (Punjab University, Chandigarh, India)

A parametric instability occurs in a dynamical system due to a modulation of some parameter. A Taylor-Couette system consisting of a viscous, incompressible flow of a Newtonian fluid in an annular region between to coaxial rotating cylinders is a good model to study this instabilty. Parametric instability in the viscous Taylor-Couette flow can appear by a time periodic oscillation of one or both the cylinders or a time periodic oscillation of the azimuthal velocity of the basic flow. The instability can also arise in the Taylor-Couette flow of a ferrofluid, via modulation of an axially applied periodically oscillating magnetic field to the system. We have investigated the response of the Couette-Taylor instability to the parametric modulation of a periodically oscillating magnetic field applied axially, using the classical Floquet theory.

IC/PP2032/101: **On the stability of forced KdV equation and forced modified KdV equation.**

Presenter: Jeongwhan Choi (Korea University, Republic of Korea)
Co-author: Sungim Whang (National Institute for Mathematical Sciences, Republic of Korea)

We derive both the time dependent Forced KdV and time dependent Forced Modified KdV equaion as model equations of a two layer incompressible immiscible and inviscid fluid over a small obstruction at the rigid bottom according to the variation of density ratio and depth ratio. By studying the equations both numerically and theoritically, we show the existence of the cut-off values of Froue number above which steady solution exist and below which no steady solution exist. The numerical stability of both Forced KdV equation and Forced Modified KdV equation are also carried out in this research.

IC/PP2613/101: **Geometrical effect of resonant gas oscillation excited in annular cavities.**

Presenter: Eru Kurihara (Hokkaido University, Japan)

The nonlinear resonance of cylindrical acoustic standing waves of an ideal gas contained between two coaxial cylinders is theoretically and numerically investigated. The wave motion concerned is excited by a small-amplitude harmonic oscillation of the radius of the outer cylinder, and the formulation of the problem includes the wave phenomenon in a hollow cylinder without the inner one as a limiting case. The spherical standing wave in two concentric spheres is also studied in parallel. The resonance occurs if the driving frequency falls in a narrow band around the linear resonance frequency, and in the weakly nonlinear regime, no shock wave is formed in contrast to the plane wave resonance. A cubic nonlinear equation for complex wave amplitude can then be derived by the method of multiple scales. Using a first integral of the cubic nonlinear equation, we shall demonstrate that the resonant oscillation is accompanied by a periodic modulation of amplitude and phase when the dissipation effect due to viscosity and thermal conductivity is negligible. The period of the modulation varies as the minus two-thirds power of the acoustic Mach number defined at the outer cylinder or sphere and decreases with an increase in the radius ratio of the inner and outer cylinders or spheres. When the dissipation effect is small but not negligible, the modulation is slowly weakened and the resonant oscillation approaches a steady state oscillation, which corresponds to the steady solution examined in earlier works. In the resonant oscillation generated between two eccentric cylinders, depending on the frequency of the sound source, axially symmetric or alternate oscillationg mode can be generated even if the sound source oscillates uniformly about the axis.

IC/PP4157/102: **Instability of uniformly-magnetized plasma and nonextensive theory.**

Presenter: Priyadarshi Patni (Jodhpur, India)
Co-author: Aiyub Khan (Jodhpur, India)

The dynamics of a self-gravitating, uniformly-magnetized plasma is studied in order to examine the propagation of hydromagnetic instabilities. The Jeans criterion is analyzed for modification due to nonextensive effects and the presence of an external magnetic field in the framework of Tsallis statistics. It is found that the Jeans instability is indeed modified by both these effects. A simple generalization of the Jeans criterion is derived.

IC/PP4706/103: **Analysis of the ice flow near the *grounding line*.**

Presenter: Ana Isabel Muñoz (Rey Juan Carlos University, E.S.C.E.T., Spain)

In this work we study one of the problems that has attracted more attention in the scientific community interested in the motion of glaciers, which is the *grounding-line* dynamics. The grounding line is the line where transition between ice attached to the solid ground and ice floating over the sea takes place. It is widely recognized that the ice flow behaviour in a neighborhood of the grounding line plays a very important role in the stability of the ice sheet. An example of this situation can be found in the West Antarctic Ice Sheet (W.A.I.S.).

We analyze a mathematical model describing the ice flow near the grounding line where the ice is considered a non-Newtonian fluid. To precise, we consider a stationary ice sheet modelled as a Stoke's flow in a bounded two-dimensional domain. The boundary that locates the interface ice–sea water is supposed to be unknown and determining its geometry and location is part of the problem. We prove the existence an uniqueness (in a sense to be defined) of weak solutions and find the regularity of the free boundary. We solve numerically the problem in a neighborhood of the grounding line, with a shooting method combined with an Euler one, in order to study locally the behavior of the velocity and stress fields. Finally, we present and discuss the numerical results for the problem in the whole domain, obtained with a finite-element method.

This is work done in collaboration with Marco A. Fontelos and Emanuele Schiavi.

IC/PP3051/106: **Riemann problem for a hyperbolic system of conservation laws in MHD.**

Presenter: Raja Sekhar Tungala (IIT Bombay, India)

We consider the Riemann problem for the system of equations which govern the one dimensional unsteady simple flow of an isentropic, inviscid and perfectly conducting compressible fluid, subjected to a transverse magnetic field . We show that system is hyperbolic, and establish existence of shocks and rarefaction waves. We prove the stability conditions for both the shocks and discuss how velocity and density vary across shocks and rarefaction waves. We show that the characteristic speed increases from left to right for rarefaction waves. We discuss properties of rarefaction curves and show that shock curves are starlike with respect to a some fixed point. We discuss the geometry of shock curves in Riemann invariant coordinates. We consider the Riemann problem for arbitrary initial data and show the existence and uniqueness of the solution under certain conditions. We discuss the vacuum state in isentropic magnetohydrodynamics. Finally we discuss the interaction of elementary waves obtained from the Riemann problem.

IC/PP805/106: **Mathematical simulations of flows in a tank containing an open elastic cylinder.**

Presenter: Lee Wanho (Wanho Lee, Republic of Korea)

Mathematical simulations of flows driven by pumping without valve was originally introduced by Jung using the immersed boundary method. Like many problems in biofluid mechanics, this can be modeled as the dynamic interaction of a viscous incompressible fluid (the blood) and elastic boundaries. In the present work, we consider a fluid filled tank with an open cylinder consisting a soft and rigid boundary. A periodic compression and decompression of the soft part generates a unidirectional flow. Both size and the direction of the generated net flow depend on the pumping frequency and amplitude.

11: Chemistry and Materials, Minisymposia

IC/MP80/011: **Multilinear decomposition: theory and applications.**

Organiser: Ilgis Ibragimov (Universität des Saarlandes, Germany)
Co-organiser: Vladislav Orekhov (Göteborg University, Sweden)

This minisymposium aims to bring together the world's leading researchers in multi-dimension and tensor decompositions.

The multi-dimension decomposition problem reads as following: let $f(x_1,\dots,x_d) \in \mathbb{C}$, with $x_1,\dots,x_d \in \Omega_d$, for given $d \in \mathbb{N}$ with $d > 2$. the aim is to find the rank-r decomposition through skeleton vectors $b_i^{(p)}(x_p)$, for $i = 1,\dots,r$ and $p = 1,\dots,d$, such that

$$f(x_1,\dots,x_d) \simeq \sum_{i=1}^{r} b_i^{(1)}(x_1)\dots b_i^{(d)}(x_d)\,.$$

Multi-dimension decomposition was first discussed in the works of Sokolov (1960) and Harshman (1971), but since that time it has still not been fully investigated. On the other hand, there is a strong interest to this decomposition in chemistry and physics. It is used for signal processing in telecommunications, optical and fluorescence spectroscopy, and in high-performance liquid chromatography. Another use[1] of this decomposition is for High-Resolution Multi-Dimensional NMR Spectroscopy, which makes a jump into the future for biochemistry.

Optimization of resolution and sensitivity of NMR spectra using sparse matched data acquisition and multi-dimensional decomposition. **Vladislav Orekhov** (Göteborg University, Sweden) IC/MT2937/011

An overview of latest advances in the MDD methodology in the field of biomolecular NMR is presented. Reconstruction of a multidimensional spectrum from a non-uniformly sampled time signal is the equivalent to prediction of data lacking actual measurements. The mathematical model of the MDD assumes that all essential features of a M-dimensional matrix can be described as the sum of a small number of tensor products of one-dimensional vectors. When MDD is applied to NMR, the matrix corresponds to an input multidimensional time series, whereas the vectors represent output line-shapes. One of the merits of the original MDD method is that it does not apply any constraints on the appearance of the line-shapes. However, using a model with a smaller number of adjustable parameters has an advantage that a bigger fraction of missing data can be predicted. In most practical cases, the NMR theory predicts the autoregressive property of the time domain signal exemplified by a superposition of sine waves decaying with time.

We show that the autoregressive assumption can be incorporated into the MDD signal processing. In particular, each of the time domain shapes of length N in the original MDD model is recursively subjected to additional MDD decomposition to a product of K vectors of length d so that $N = dK$. This converts the original M-dimensional decomposition to $(M-1+K)$-dimensional one, which we entitle R-MDD. The aim of the second MDD decomposition is to reduce the number of unknowns in the least-square minimization in the MDD model. The original vectors with N unknown elements are defined by much smaller number of parameters $(d-1)\log_d(2N)$. The method allows to speed-up recording of high-resolution NMR spectra. In particular, logarithmic dependence on the dimension sizes and linear dependence on spectrum dimensionality essentially eliminates any practical restrictions on these parameters. For example, a $5D$ experiment with all indirect dimensions sizes of 100 points would take 101 years of measurement time using conventional uniform sampling scheme. R-MDD can sample such a spectrum in 2.4 hours, which is 13 times faster than offered by the original MDD processing. We demonstrate performance for several triple resonance experiments recorded on three globular proteins with molecular weights 8-22 kDa. For one of these systems good results are demonstrated with fraction of missing data of 94%, target spectra sizes of $400\times60\times100$ complex points, and number of spectral components 480.

This work was performed as a collaboration with V. Jaravine and I. Ibraghimov.

Multi-dimensional decomposition of projected spectra obtained in protein NMR. **Martin Billeter** (Göteborg University, Sweden) IC/MT2776/011

Nuclear Magnetic Resonance (NMR) is a very versatile tool in protein research, e.g. for the development of clinically active compounds (*drug discovery*). The often several thousands signals in a NMR spectrum characterize structure, dynamics and interactions of proteins. These spectra are recorded as N-dimensional matrices with a few hundred data points along each dimension. Thus, conventional NMR experiments with $N \geq 5$ would yield matrices of excessive size (and require impossible measurement times). However, similar information to that of a spectrum with $N \sim 10$ is obtained by recording projections of such a spectrum. NMR theory describes the output of an N-dimensional experiment as

$$s(t_1,t_2\dots t_N) = \sum_k f_1(t_1)\otimes f_2(t_2)\dots\otimes f_N(t_N),$$

where t_i are time parameters of the experiment (called *evolution times*) and the functions f_i are of type $a\cdot\exp((i\omega-\lambda)\cdot t)$. The spectrum follows from Fourier transformation along all dimensions:

$$S(\omega_1,\omega_2,\dots,\omega_N) = \sum_k F_1(\omega_1)\otimes F_2(\omega_2),\dots,\otimes F_N(\omega_N)\,.$$

This equation describes a multidimensional decomposition with the experimental input on the left side and a characterization of the signals as the output on the right side. Projected spectra result from the coupling of evolution times: $t := c_1\cdot t_1 = c_2\cdot t_2,\dots = c_{N-1}\cdot t_{N-1}$. The projected spectrum becomes (after Fourier transform $t\to\omega, t_N\to\omega_N$)

$$S(\omega,\omega_N) = \sum_k (F_1\star F_2,\dots)(\omega)\otimes F_N(\omega_N)\,,$$

where $\star$ denotes convolutions. An implementation of an optimization procedure using the last equation to determine the functions F_i will be presented and applied to an experimental input of about 50 projected spectra with similar information content than a hypothetical 7-dimensional spectrum $S(\omega_1,\dots,\omega_7)$. The resulting F_i allow, using the second equation, reconstruction of parts of this spectrum $S(\omega_1,\dots,\omega_7)$, but they can also be directly interpreted to extract the desired signal information. Applications will be shown for protein molecules consisting of ~ 2500 atoms with the goal to identify their individual resonance frequencies.

Best rank-(R_1, R_2, R_3) approximation of third-order tensors, based on the Riemannian trust-region scheme. **Mariya Ishteva** (Katholieke Universiteit Leuven, Belgium), Lieven De Lathauwer (CNRS-ETIS, France), Pierre-Antoine Absil (Université Catholique de Louvain, Belgium), Rodolphe Sepulchre (Université de Liège, Belgium), Sabine Van Huffel (Katholieke Universiteit Leuven, Belgium) IC/MT1992/011

For matrices, the truncated Singular Value Decomposition (SVD) provides the best low-rank approximation. However, for tensors, the truncated Higher-Order SVD (HOSVD) [2], which is a generalization of SVD to higher-order tensors, gives a sub-optimal low-rank approximation, that can only be used as a starting value for iterative algorithms.

In this talk we propose an iterative algorithm for computing the best rank-(R_1, R_2, R_3) approximation of third-order (unstructured) tensors. We express the tensor approximation problem as minimizing a cost function on a manifold (a product of three Grassmann manifolds) and apply the Riemannian trust-region scheme [1], using the truncated conjugate-gradient method for solving the trust-region subproblem. Making use of second order information about the cost function, superlinear convergence is achieved. We present some simulation results.

(For abstract, see session #1 above.)

Multi-dimensional decomposition (MDD) of spontaneous electroencephalogramm (EEG). **Elena Orekhova** (Sahlgrenska University Hospital, Sweden) IC/MT3183/011

Electrical activity of the brain is essentially rhythmic. The functional coupling of a number of cortical brain regions is reflected by coherence or the rhythmic signals at corresponding EEG derivations. MDD is a powerful tool for analysis of complex multidimentional experimental data. We applied recursive MDD approach (Jaravine et al. Nature Methods 2006, 3: 605-607) to decompose EEG signal on a number of functional processes characterised by a frequency, phase and distribution over the head surface. In this study we used complex 10-12 dimensional decomposition with 2-20 components to deal with 2.7×10^5 complex data points. The calculations on simulated EEG signals were performed to evaluate potentials of the method for analysis of the real EEG. Preliminary results on EEG recorded during sustained visual attention in children are presented.

Solution of industrial linear systems with structured matrices. **Elena Ibragimova** (Elegant Mathematics Ltd., Germany) IC/MT3150/011

In this talk we present a "gray box" solver for large sparse linear system of equations and test it with different industrial problems. This solver utilize matrix entries and the grid where this matrix is generated.

If the system matrix uses a tensor grid, we use the Kronecker product approach, which can solve the system with linear and, in some cases, with sublinear complexity. In the case of general adaptive grids — a general sparse ILU preconditioners are used. The complexity and memory requirements of Kronecker product approaches are usually better than for the general ILU preconditioners. From the other hand, the adaptive grid without tensor structure can give better approximation of physical phenomena.

The main message of this talk is to compare an accuracy achieved in different grids using the best suitable approach for the solution of the linear system generated on several industrial problems. We present several numerical experiments and show that the answer to the question "which method is faster" is not evident for the most problems and it depends on many factors.

Problems in practical application of high-resolution numerical schemes to internal and external tasks of aerodynamics. **Egor Kazhan** (Central Aerohydrodynamic Institute, Russian Federation), Vladimir Vlasenko (Central Aerohydrodynamic Institute (TsAGI), Russian Federation), Sergey Bosniakov (Central Aerohydrodynamic Institute (TsAGI), Russian Federation), Sergey Glazkov (Central Aerohydrodynamic Institute (TsAGI), Russian Federation), Vladimir Jitenev (Central Aerohydrodynamic Institute (TsAGI), Russian Federation), Juergen Quest (European Transonic Windtunnel, Germany), Sergey Mikhailov (Central Aerohydrodynamic Institute (TsAGI), Russian Federation) IC/MT2618/011

This report presents numerical method for solution of aerodynamic tasks on the basis of Reynolds Averaged Navier-Stokes Equations. The method is applied to simulation of flow around aircraft (including engine-airframe interference) and to description of flowfield in the wind tunnel (WT) with aircraft model inside. Because of growing practical requirements both to accuracy of numerical results and to calculation time, further improvement of numerical methods is necessary. Possible way is optimal combination of explicit and implicit schemes. Advantages of explicit schemes - small cost per one time step and relatively small errors in simulation of unsteady processes. But strong time step restriction leads to huge computation times in tasks with vastly different linear scales. Implicit schemes may be stable for each value of time step. But they produce high errors in description of unsteady processes and high cost per time step. We recommend zonal approach: flow regions with small scales of physical phenomena may be described using implicit scheme, and the rest of the flowfield - using explicit scheme. Further in the report, examples of the existing numerical method application to practical tasks of aerodynamics are presented. Numerical calculations may be used at various stages of experiment preparation: they aid to choose the placement of gauges, to avoid errors during tests, to interpret the obtained data, to adjust WT wall perforation and to eliminate errors caused by WT walls influence on the model. An example of modeling flow in the test section of European Transonic Windtunnel is shown. Unsteady phenomena around WT slotted walls were obtained.Calculations of noise suppressing nozzles with different geometry are considered. Numerical simulation has allowed to improve the nozzle geometry and to provide essential noise suppression. All presented examples confirm the need in further development of effective and accurate algorithms for practical tasks solution.

Fast numerical solution of Boltzmann equation. **Ilgis Ibragimov** (Universität des Saarlandes, Germany) IC/MT3090/011

This talk consider a fast numerical solution of the classical Boltzmann equation for a simple, dilute gas of particles:

$$f_t + (v, \nabla_x f) = \int_{\mathbb{R}^3} \int_{S^2} B(v, w, e)(f(v')f(w') - f(v)f(w))\mathrm{d}e\mathrm{d}w\,,$$

where

$$f(t, x, v) : \mathbb{R}_+ \times \Omega \times \mathbb{R}^3 \to \mathbb{R}_+$$

describes the time evolution of the particle density.
It is observed that the particle density function can be considered as low multi-dimensional rank function and reads in the form

$$f(t, x, v) = \sum_{i_1, i_2, i_3}^{r_1, r_2, r_3} f_{i_1}^{(1)}(t, v_1, x) f_{i_2}^{(2)}(t, v_2, x) f_{i_3}^{(3)}(t, v_3, x) g_{i_1, i_2, i_3},$$

where r_1, r_2, r_3 are almost constants.

This approach needs $\mathrm{O}(n)$ words of memory for each grid points of domain discretisation, which is comparable to descretisation of Navier–Stokes equations, but produce better numerical accuracy. Here n denotes the number of discretisation points in one direction of the velocity space.

The method has been tested on an industrial example of supersonic flight simulation with Mach number > 10, having 1.2 million grid points in the domain Ω, and $n = 64$. The simulation takes several days using a modern PC. To obtain a similar result by other deterministic methods one should use a supercomputer having terabytes of main memory.

IC/MP192/015: Mathematical models for cultural heritage.

Organiser: Roberto Natalini (Consiglio Nazionale delle Ricerche, Italy)
Co-organiser: Antonio Fasano (Università di Firenze, Italy)

The minisymposium aims to present some current researches about the rational assessment and quantitative prediction of damage in cultural heritage, with a specific focus on surface and structural damage in natural stones and concretes used in historical buildings or artifacts, through a systematic use of mathematical models. The presentations will be concerned with phenomena occurring under the combined attack of different aggressive agents like pollution, weathering, moisture, vibrations, and thermal variations.

Free-boundary models of sulphation: swelling and the influence of humidity. **Fabrizio Clarelli** (Consiglio Nazionale delle Ricerche, Italy), Antonio Fasano (Università di Firenze, Italy), Roberto Natalini (Consiglio Nazionale delle Ricerche, Italy) IC/MT1412/015

Deterioration of stones is a complex problem and one of the main concern for people working in the field of conservation and restoration of cultural heritage. It is extremely difficult to isolate a single factor in this kind of processes, which are the results of the interaction of various mechanisms, many of which also occur in natural weathering, even is atmospheric pollution can be considered as one of the most important factor of damage. Here, we introduce some free boundary models which describe the evolution of calcium carbonate stones under the attack of atmospheric SO_2, taking into account both swelling of the external gypsum layer and the influence of humidity. Different behaviors are described according to the relative humidity of the environment, and in all cases reliable explicit asymptotic approximations are introduced under reasonable assumptions on the data. Numerical simulations are introduced and discussed.

Fracture of concrete due to corrosion. **Yves Berthaud** (Université Pierre et Marie Curie, France), Caré Caré (Laboratoire Central des Ponts et Chaussées, France), Ragueneau Ragueneau (LMT Cachan, France), Thanh Thanh (LMT Cachan, France), Millard Millard (Commissariat à l'Energie atomique, France), L'Hostis (Commissariat à l'Energie atomique, France) IC/MT1817/015

Cracking of concrete due to corrosion is a very common pathology that can be observed on various structures. Corrosion is initiated by the penetration of chlorides or of carbon dioxide in most cases. The consequences of corrosions are (i) the reduction of the resistive section of reinforcements (ii) the creation of expansive products (commonly denoted rust) (iii) the fragilization of steel and finally (iv) the cracking of concrete. Three stages are distinguished: (1) the incubation that corresponds to diffusion processes of chemical species (ions) inside concrete from the free surface to the steel concrete interface ; (2) the initiation stage starts when the passivation film is broken ; (3) the cracking stage corresponds to the end of the initiation and to the lack of carrying capacity of the structure. We have decided to study this stage in Laboratory. The first stage takes decades for real cases. In our study it has been speeded by the use of accelerated corrosion under the effect of imposed electrical current with the addition of chorides in the mixture (they act as a catalyser for the chemical reaction). We decided to impose the electrical current density that allows to predict (using the FaradayŠs law) the production of iron oxides. The imposed values range between 1 and $5A/m^2$. We have designed various types of specimens for plane strain and plane stress analyses. They give us the possibility to record digital images that are analysed through the LMT-soft Correli ; it computes both the in plane displacement and the plane strain fields. It is possible to derive the kinetics of damage that has been proved to be similar to what happens in real structures (for natural corrosion). A finite element modelling has been developed based on a classical damage model for concrete, on the identified properties of iron oxides (very low stiffness) and on the use of special interface elements. The growth of oxyde layer is obtained via an imposed fictitious thermal load the rate of which is calibrated to fit real data (measured using long distance microscope).

Progress and challenges in modelling salt damage to building stones. **Heather Viles** (University of Oxford, UK) IC/MT2677/015

Much important built heritage worldwide is composed of porous building stones, and many of these stones are at risk of damage from salt crystallisation. Salts may enter porous stone dissolved in groundwater or precipitation, and come from sources as diverse as air pollution, deicing salts, dust and natural weathering. Damage to stonework occurs when salts within pores repeatedly crystallise, dissolve and recrystallise, exerting pressures on the pore walls which eventually result in failure (often in the form of crack propagation and spalling). There has been a long history of field and laboratory-based studies on salt crystallisation, and more recently a variety of attempts have been made to model the processes at work. We review some recent models which have focused either on what happens in single pores or on the larger scale development of decay features such as alveoli. We suggest some potentially valuable new approaches to the problem, with a view to providing a more complete model of how salt crystallisation causes damage to stonework.

Wetting of rough surfaces. **Antonio DeSimone** (SISSA, Trieste, Italy) IC/MT3905/015

We discuss wetting properties of chemically or topographically patterned surfaces. In particular, we analyze the effect of roughness on the apparent contact angle and contact angle hysteresis through a variational approach and homogenization techniques. Perspectives for the analysis of graffiti damage and antigraffiti measures for monuments and buildings will be discussed. This is joint work with G. Alberti, N. Grunewald, and F. Otto.

IC/MP999/110: Electronic structure calculation.

Organiser: Reinhold Schneider (Universität Kiel, Germany)

The electronic Schrödinger equation describes the non-relativistic behaviour of a quantum mechanical N-electron system under the influence of Coulombic potentials. It is the basic equation for ab initio numerical simulation of phenomena on an atomic or molecular scale. Density functional theory provide effective one particle models to circumvent the approximation of the wave function in high dimensions. Approaches which scale linearly with respect to the number of atoms could provide tools for computing extremely large molecules or atomic clusters up to the systematic error of the underlying DFT model. The approximation of the high dimensional wave function is extremely difficult, Recent regularity and approximation results indicate that the wave functions can be approximated with a polynomial instead of an exponential scaling w.r.t. to the number of particles. Highly accurate computational results for the correlation energy are achieved by the coupled cluster method, frequently used in quantum chemistry.

Convergence of the coupled-cluster method. **Reinhold Schneider** (Universität Kiel, Germany) IC/MT3748/110

The coupled cluster (CC) method is known to provide a powerful approach for the numerical computation of correlation energies if dynamic correlation effects are dominating. It provides an approximation of the solution of the electronic Schrödinger equation. The convergence behaviour of the projected coupled cluster method (brievely called coupled cluster method) is considered. This method is introduced as an approximation of the full CI solution. Error estimates for the energies are shown by a Aubin Nitsche type arguments using the dual weighted resiual approach.

Towards an a posteriori *error representation to the Hartree–Fock equations.* **Stephan Schwinger** (Max-Planck-Institut Leipzig, Germany) IC/MT3752/110

The Hartree-Fock equations are of basic interest in *ab initio* quantum chemistry. They constitute a nonlinear eigenvalue problem, which has to be solved numerically. This means one has to select an efficient basis for discretizing this problem. In the chemical community, the approximation error commited thereby has hardly been analysed. In the last decade, *a posteriori* error estimation has grown an important tool for the determination of the approximation space for partial differential equations. Often, one is not interested in the error of the approximate solution with respect to some global norm, but rather to improve the error in the value of some target functional computed from it. This is the aim of the so-called Dual Weighted Residual Method, which we want to apply to the Hartree-Fock equations.

Fast wavelet-based methods for electrostatic and quantum mechanical problems. **Stefan Goedecker** (Universität Basel, Switzerland) IC/MT3899/110

Electronic structure calculations require to solve Poisson's and Schrödinger's equations. First, a family of methods will be presented that allows to solve electrostatic problems for both continous and discrete charge distributions with $N\log(N)$ scaling under various boundary conditions. These methods are thus an alternative to fast multipole, particle mesh and plane wave methods. Second, it will be shown how Daubechies' wavelets can efficiently be used as a basis set for pseudo-potential density functional calculations.

Sparse grids, adaptivity, and symmetry. **Andreas Zeiser** (TU Berlin, Germany), Harry Yserentant (TU Berlin, Germany) IC/MT3915/110

Sparse grid methods represent a powerful and efficient technique for the representation and approximation of functions and particularly the solutions of partial differential equations in moderately high space dimensions. To extend the approach to truly high-dimensional problems as they arise in quantum chemistry, an additional property has to be brought into play, the symmetry or antisymmetry of the functions sought there. In the talk, an adaptive sparse grid refinement scheme is presented that takes full advantage of such symmetry properties and for which the amount of work and storage remains strictly proportional to the number of degrees of freedom. To overcome the problems with the approximation of the inherently complex antisymmetric functions, augmented sparse grid spaces are proposed.

IC/MP30/111: Kinetic Monte-Carlo methods.

Organiser: Tim Schulze (University of Tennessee, USA)
Co-organiser: Shaun Hendy (Industrial Research Ltd, New Zealand)

Kinetic Monte Carlo (KMC) is a stochastic simulation technique widely used to study epitaxial growth, chemical kinetics and other discrete stochastic processes. With its growing popularity, a large number of novel techniques and algorithmic improvements are emerging. The minisymposium will cover a range of these emerging methods, including hybrid simulation techiques, self-learning and adaptive KMC, off-lattice KMC, parallel implementation and fast algorithms.

Rare events in kinetic Monte-Carlo. **Eric Vanden-Eijnden** (Courant Institute, NYU, USA) IC/MT958/111

In this talk, rare events in the context of continuous-time Markov jump processes and networks will be discussed. In particular, it will be shown how Freidlin-Wentzell theory of large deviations can be used to design an efficient numerical technique, termed the minimum action method, to determine the pathways of maximum likelihood of hopping events between metastable basins as well as the rate of occurence of these events. The method will be illustrated on some chemical and biological networks.

Efficient computation of heteroepitaxial growth. **Peter Smereka** (University of Michigan, Ann Arbor, USA) IC/MT1168/111

The growth of strained heteroepitaxial films using a Solid-on-Solid model KMC is discussed. Elastic effects are included by using a ball and spring model. Discrete models of this form naturally include nanoscale effects, such as nucleation, which are difficult to incorporate in continuum models. On the other hand, it is more computationally intensive to use these discrete models to simulate film growth on experimentally relevant length scales. This talk will discuss some of the computational challenges and approaches we have developed for simulation of heteroepitaxy. In particular, I will discuss a multigrid-Fourier method for rapid solution of the displacement field, an expand box method which allows very quick local corrections to the displacement field, and a rejection-reduced KMC method which uses fast estimates of the hopping rates. Preliminary results of film growth will be presented which shows that when the elastic effects are small the film grows in a layer-by-layer fashion. However, when the elastic effects become strong we observe strain relaxed three dimensional islands sometimes called self-assembled quantum dots.. This is joint work with Giovanni Russo and Tim Schulze.

A hybrid kinetic Monte-Carlo molecular dynamics method for modeling epitaxial growth. **Shaun Hendy** (Industrial Research Ltd, New Zealand), Tim Schulze (University of Tennessee, USA), Peter Zoontjens (Victoria University of Wellington, New Zealand) IC/MT1235/111

The disparate time and length scales involved in the epitaxial growth of thin films pose an enormous challenge for simulation. A popular and powerful approach to the simulation of such processes is the kinetic Monte Carlo (KMC) method, especially when combined with first principles determinations of rates. While the standard KMC method assumes that atoms reside on a perfect lattice, this approximation is not always appropriate. For instance, growth on a fcc (111) surface can lead to the formation of both fcc and hcp islands, and the subsequent the formation of grain boundaries as these islands impinge. While the mobility of grain boundaries is an important factor in determining the quality of thin films, this may be poorly described by the usual lattice approximation favored by standard KMC. Molecular dynamics (MD) on the other hand does not rely on a lattice approximation. With an appropriate potential energy function, one would expect MD to give an accurate description of the structure and dynamics of a grain boundary. However, MD can only be used to simulate a relatively small number of atoms for relatively short durations due to the need to compute forces between pairs of atoms on time scales much smaller than those generally involved in KMC. This generally prohibits the use of MD in simulating epitaxial growth except in the limits of high temperatures and high deposition rates. Here we present a hybrid multiscale method which combines MD and KMC in a spatial domain decomposition in an attempt to speed up conventional MD. Near the grain boundaries, atoms are treated using MD but away from the boundaries we use KMC. We apply this method to study the motion of grain boundaries during epitaxial growth.

IC/MP30/111: Kinetic Monte-Carlo methods. #2

Organiser: Tim Schulze (University of Tennessee, USA)
Co-organiser: Shaun Hendy (Industrial Research Ltd, New Zealand)

(For abstract, see session #1 above.)

Fast kinetic Monte-Carlo algorithms. **Tim Schulze** (University of Tennessee, USA) IC/MT2035/111

Two new algorithms for KMC simulations designed to give a fixed single-event execution time as the system size is increased will be described. These algoithms address systems with large event lists and disparate rates that do not cluster at a small set of discrete values. The methods will be demonstrated using models for crystal growth.

Numerical analysis of coarse-graining in stochastic simulations. **Petr Plecháč** (Univ. Tennessee & Oak Ridge National Lab, USA) IC/MT2718/111

We shall discuss some general mathematical and numerical issues arising in simulations where the microscopic Markov process is approximated by a hierarchy of coarse-grained processes. We shall present mathematical tools (e.g., entropy estimates estimates) for error estimation of the coarse-graining procedure. The techniques will be explained in specific examples of lattice as well as off-lattice dynamics and various types of error control will be presented. Analysis of convergence to equilibrium will be also discussed. Numerical evidence supported with rigorous analysis indicates regimes in which the coarse-grained Monte Carlo algorithm probes efficiently energy landscape and provides accurate approximation of sampled quantities.

Self-learning kinetic Monte-Carlo simulations: application to epitaxial growth processes. **Talat Rahman** (University of Central Florida, USA) IC/MT3789/111

Coupled with advances in ab initio methods for the calculation of activation energy barriers, the kinetic Monte Carlo (KMC) method is proving itself to be an important tool for computational studies of phenomena such as epitaxial growth, surface diffusion and surface morphological evolution. However, despite its ability to carry out simulations for time and length scales that are relevant to experiments, in its nascent form the method has limited predictive power because of its reliance on predetermined atomic events and their energetic as input. To overcome this handicap, we have developed a self learning method (SLKMC) within the lattice gas model, in which we combine standard KMC with automatic generation of a table of microscopic events, facilitated by a pattern recognition scheme. Each time the system encounters a new configuration, the algorithm initiates a procedure for saddle point search around a given energy minimum. Nontrivial paths are thus selected and the fully characterized transition path is permanently recorded in a database for future usage. The system thus automatically builds up all possible single and multiple atom processes that it needs for a sustained simulation. Results of the application of the method to examination of the diffusion and coalescence of 2-dimensional Cu and Ag adatom and vacancy clusters on Cu(111) and Ag(111) will be presented. I will highlight the key role played by specific diffusion processes revealed during the simulation. Of particularly interest are multiple atom processes whose presence may have been ignored otherwise. As we will see the importance of such processes is dependent on both cluster size and surface temperature. For adatom clusters varying in size from 2 to 1000, I will discuss the size dependence of the diffusion coefficient and the effective energy barrier. The rate limiting processes will also be discussed for island coalescence. Results will be compared with those from experiments, where available, and with those from KMC simulations based on a fixed catalogue of diffusion processes. I will also provide some details of an extension of the techniques to Şoff-latticeŤ case and its application to examine the case of heteroepitaxial growth.

IC/MP286/112: Recent development in the mathematical theory of polymeric materials: modeling, numerical simulation, and analysis.

Organiser: Bo Su (Iowa State University, USA)
Co-organiser: Vincenzo Capasso (Università degli Studi di Milano, Italy)

This minisymposium is to provide a forum to foster research exchange and collaboration among active reseachers in the area who are addressing the fundamental problems from crystal growth, crystal nucleation, polymer nanocomposite to polymeric fluid.

Random geometric birth-and-growth processes in material sciences and biomedicine. **Vincenzo Capasso** (Università degli Studi di Milano, Italy) IC/MT3377/112

Nucleation and growth processes arise in a variety of natural and technological applications, such as solidification of materials, semiconductor crystal growth, biomineralization (shell growth), tumour growth, vasculogenesis, etc. All these processes may be modelled as birth-and-growth processes (germ–grain models), which are composed of two processes, birth (nucleation, branching, etc.) and subsequent growth of spatial structures (crystals, vessel networks, etc), which, in general, are both stochastic in time and space. These structures usually induce a random division of the relevant spatial region, known as a random tessellation. A quantitative description of the spatial structure of a random tessellation can be given, in terms of the mean densities of interfaces (n-facets) of the random tessellation, at different Hausdorff dimensions (cells, faces, edges, vertices), with respect to the usual d-dimensional Lebesgue measure. In Material Science mechanical properties of the final material strongly depend on the mean densities of the interfaces. Predictive mathematical models which are capable of producing quantitative morphological features can contribute to the solution of optimization or optimal control problems. A non-trivial difficulty arises from the strong coupling of the kinetic parameters of the relevant birth-and-growth (or branching-and-growth) process with the underlying field, such as temperature, and the geometric spatial densities of the evolving spatial random tessellation itself. Methods for reducing complexity include homogenization at mesoscales, thus leading to hybrid models (deterministic at the larger scale, and stochastic at lower scales).

Ginzburg–Landau minimizers with prescribed degrees: emergence of vortices and existence/nonexistence of the minimizers. **Leonid Berlyand** (Pennsylvania State University, USA) IC/MT1475/112

Let Ω be a 2D domain with a hole ω. In the domain $A = \Omega \setminus \omega$ consider a class $\mathcal{J}$ of complex-valued maps having degrees 1 and 1 on $\partial\Omega$, $\partial\omega$ respectively.

In a joint work with P. Mironescu we show that if $\mathrm{cap}(A) \geq \pi$ (subcritical domain), minimizers of the Ginzburg-Landau energy E_κ exist for each κ. They are vortexless and converge in $H^1(A)$ to a minimizing S^1-valued harmonic map as the coherency length κ^{-1} tends to 0. When $\mathrm{cap}(A) < \pi$ (supercritical domain), for large κ, we establish that the minimizing sequences/minimizers develop exactly two vortices—a vortex of degree 1 near $\partial\Omega$ and a vortex of degree -1 near $\partial\Omega$ which rapidly converge to ∂A. It was conjectured that the global minimizers do not exist for large κ.

In a subsequent joint work with D. Golovaty and V. Rybalko this conjecture was proved. It was shown that, when $\mathrm{cap}(A) < \pi$, there exists a finite threshold value κ_1 of the Ginzburg–Landau parameter such that the minimum of E_κ is not attained in $\mathcal{J}$ when $\kappa > \kappa_1$, while it is attained when $\kappa > \kappa_1$. No standard elliptic estimates worked here and our proof is based on an introduction of an auxiliary linear problem which allows for an explicit energy estimate which is sufficiently tight.

Ginzburg–Landau equations with two order parameters. **Daniel Phillips** (Purdue University, USA) IC/MT3334/112

We study a G-L model for high-T_c superconductivity described with two complex valued order parameters; a dominant d-wave component and a small admixture of an s-wave component. In this model, if the s-d mixing parameter is zero then the system reduces to the standard single component G-L equation. We investigate the case of a small mixing parameter and the nucleation of the second component. This is joint work with Minkyun Kim.

Modelling Ziegler–Natta polymerization in high-pressure reactors. **Alberto Mancini** (Università di Firenze, Italy), Antonio Fasano (Università di Firenze, Italy) IC/MT601/112

The Ziegler–Natta process in its modern version, using spherical catalyst support in high-pressure reactors, is the most efficient and economic way of producing polymers of ubiquitous use such as polypropylene and polyethylene. Using the ideas of previous works as a starting point, we present a mathematical model encompassing for the first time the mechanical behavior of the polymer while it grows around the nanometric catalytic particles. As a theoretical basis for the description of the growing continuum we use the theory of *Natural Configurations* of K.R. Rajagopal and L. Tao.

Interfacial flows with surfactant. **John Lowengrub** (University of California, Irvine, USA) IC/MT3244/112

In this talk, I will present Eulerian methods for the simulation of fluid interfaces with surfactant using a level-set method. The methods couple an implicit discretization of the surfactant equation with the immersed interface flow-solver. Novel techniques are used to accurately conserve component mass and surfactant mass during the evolution. The method is applied to study the effects of surfactants on single drops, drop-drop interactions and interactions among multiple drops in Stokes flow under an applied shear. A non-monotonic behavior of the minimum distance between approaching drops versus capillary number is observed. Accordingly, a critical capillary number Ca* measuring the tendency to coalescence is determined as a function of the surfactant coverage. A transition in behavior is observed to occur at a critical coverage. This is joint work with J. Xu, Z. Li and H.-K. Zhao.

Direct and inverse modeling for stochastic data in microbead rheology with application to biological liquids. **Christel Hohenegger** (University of North Carolina, USA) IC/MT5060/112

The need in biology to understand the rheological properties of cells, tissues, membranes, and biological liquids, has led to new techniques in microrheology, where bead tracking is the fundamental probe of viscoelastic properties. We present stochastic methods for inverse characterization based on noisy time series, starting with the Mason-Weitz protocol for single bead path data, then going to the Crocker-Levine-Lubensky protocol for 2-point statistics. We build fast and statistically accurate direct simulation tools based on generalized Langevin equations, as well as inversion methods derived from maximum likelihood methodology and Kalman filter. The motivating application is to support experiments by R. Superfine and D. Hill and for characterization and simulations of transport mechanisms in lung airway surface liquids within the Virtual Lung Project at UNC Chapel Hill.

Inhomogeneous kinetic theory of liquid-crystal polymers. **Pingwen Zhang** (Peking University, PR China) IC/MT1525/112

We study the microstructure formation and defects dynamics arising in liquid crystalline polymers by a coupled kinetic-hydrodynamic multi-scale model. The kinetic model is an extension of Doi theory with a non-local intermolecular potential, including translational diffusion and density variation. LCP molecules were ensured anchoring at the boundary by an additional boundary potential, meanwhile mass conservation of LCPs holds in the whole flow region.

Plane Couette flow and pressure-driven Poiseuille flow are studied using the kinetic-hydrodynamic model. In plane Couette flow, the numerical results show that: 1) not only all of four in-plane modes reported by Rey and Tsuji [Macromol. Theory Simul. **7** (1998) 623–639] but also complicated in-plane modes with multi-layer defects were found; 2) some significant scaling properties were verified, such as the thickness of boundary layer is proportional to the ratio of molecular length to the size of the flow region, the tumbling period is constant in dimensionless time and has little relation with dimensionless parameters, and so on. In pressure-driven plane Poiseuille flow, the micro-morph is quasi-periodic in time when flow viscosity and molecular elasticity are comparable. Different states, such as flow-aligning, tumbling or wagging, arise in different flow region. The difference of the tumbling rate in near-by regions causes defects and form branch pattern in director spatial-temporal configuration figure.

Moment closure for FENE models of complex fluids. **Qiang Du** (Pennsylvania State University, USA) IC/MT1963/112

Moment closure not only provides a computationally feasible approach to simulate many multiscale phenomena but also offers insight to the understanding of the underlying physical processes. We will discuss some of our recent works on developing systematic moment closure models for micro-macro FENE models of complex fluids and demonstrate their effectiveness for a wide range of parameter regimes. This is a joint work with colleagues at Penn State: C. Liu, P. Yu and Y. Hyon.

Relating atomistic-to-continuum coupling and domain decomposition. **Michael Parks** (Sandia National Laboratories, USA), Pavel Bochev (Sandia National Laboratories, USA), Richard Lehoucq (Sandia National Laboratories, USA) IC/CT1316/111

The deformation and failure of many engineering materials are inherently multiscale processes. Models for such processes frequently call for decomposition of the material domain into atomistic and continuum subdomains, where the continuum subdomain is modeled via a finite element analysis. The treatment of the boundary between these subdomains, or "handshake region", is frequently what distinguishes one atomistic-to-continuum coupling method from another. A formal theory of this transition region does not yet exist. Instead, current coupling schemes employ ad hoc approximations, such as treating finite element nodes as atoms, or vice-versa, to accommodate the incompatibility between a non-local atomistic description and a local finite element description at the atomistic/continuum boundary. There currently exists little rigorous analysis of these schemes.

The atomistic-to-continuum coupling problem has similarities with the classical continuum-to-continuum domain decomposition problem. We will explore some of these similarities and address the extent to which both problems can be placed within the same mathematical and algorithmic framework. We will address domain decomposition methods that can be harnessed when solving the atomistic-to-continuum coupling problem, and for a particular coupling scheme, provide a convergence theory giving guidance about when the scheme will produce a satisfactory answer.

Modelling competition assays for electrochemical biosensors. **Dana Mackey** (Dublin Institute of Technology, Ireland), Anthony Killard (Dublin City University, Ireland) IC/CT3076/015

Biosensors are devices in constant development due to their wide use in biomedical diagnostics and environmental monitoring. Of particular interest to developing electrochemical immunosensors are enzyme channelling systems, where two enzymes are brought in close proximity to an electrode surface thus facilitating the fast conversion of initial substrate to final product.

This study compares the behaviour of an electrochemical bi-enzyme biosensor with a theoretical analysis based on a mathematical model, consisting of reaction-diffusion equations with nonlinear boundary conditions, and numerical simulations. The model describes transport processes and chemical reactions taking place in the bulk solution and at an electrode boundary, and focusses on the competition between a given antigen and its enzyme-labelled analogue for binding to electrode-immobilised antibodies. Problems of practical significance, such as determining optimal values for system design parameters with the aim of maximising the amperometric signal amplitude, while keeping non-specific interactions to a minimum, are also addressed.

Step-flow growth with anomalous diffusion. **Margo Levine** (Northwestern University, USA), Alexander Golovin (Northwestern University, USA) IC/CT2562/015

The growth of a stepped crystal surface by molecular beam epitaxy is investigated in the case when the adatom diffusion is anomalous (super-diffusion). The analog of the Burton–Cabrera–Frank theory for the case of super-diffusion is developed. The step-flow velocity is obtained as an eigenvalue of the corresponding super-diffusion problem described by a fractional PDE. The resulting crystal surface growth rate is found as a function of the terrace length and the anomalous diffusion exponent. The linear stability analysis of the step shape is performed and the super-diffusion analog of the Bales–Zangwill instability caused by the Schwobel effect is studied.

Numerical study of facetted dielectric crystal growth. **Alexander Zhmakin** (St.Petersburg Branch of Joint Supercomputer Center, Russian Federation) IC/CT3140/011

The aim of the paper is to numerically study processes at the melt/crystal interface during the growth of dielectric crystals under the action of either an intentionally introduced impurity or a local heating by a laser irradiation and to asses the effects of such interventions on the growth stability and behaviour of macrosteps on the crystal surface. The growth regimes where the undercooling of the facetted crystallization front is significant are considered.

Local computations are coupled to the global heat transfer in the whole crystal growth facility.

Computations are supported by experimental investigation of growth of bismuth germanate crystals by the crucibless AHP method.

Work done in collaboration with V.D. Golyshev.

Numerical methods for the chemical master equation and applications to stochastic models or receptor oligomerisation. **Shev Mac** (University of Queensland, Australia) IC/CT2046/015

The chemical master equation is an important model for studying chemical kinetics, especially in the context of systems biology where noise is known to play an important role and so a discrete and stochastic framework is required. However due to the high dimensional nature of the equations it has often been felt to be too difficult to tackle numerically, although recently much progress has been made. Here some novel numerical methods are presented and applied to stochastic models of receptor oligomerisation, which have previously been studied only by simulation. This gives a novel perspective on these models and suggests some insights into the phenomena of the role they play in buffering cell signals.

IC/PP2672/015: **The semi-empirical relaxation operator in quantum Liouville equation and computer simulation of two-spin system magnetic resonance spectra.**

Presenter: Vladimir Privezentsev (Institute of Physics and Technology RAS, Russian Federation)

In present work the structure of the semi-empirical relaxation operator in Liouville quantum equation was carried out. This equation for the magnetic transition M is used at computer simulation magnetic resonance spectra of a two-spin system [1]. An introduction of this phenomenological operator allows us to expand application of Liuville quantum equation to nonequilibrium processes. There are absorption by two-spin system of the superfluous μ-wave quantums and interaction of the two-spin system with environment spin medium. For the calculation of such magnetic resonance spectra a perturbation theory is not used [2].

Liouville quantum equation is written in matrix form as $\dot{M}_{mn} = \sum_{j,k} L_{mjkn}\left(M_{jk} - M_{mn}\right) + M_{mn}\sum_{j,k} L_{mjkn}$, in which $L_{mjkn} = iH_{mj}\delta_{kn} - i\delta_{mj}H_{kn}$. Here, H_{mn} is a matrix element of the spin Hamiltonian and δ_{mn} is the Kronecker delta, $\delta_{mn} = 1$ for $m = n$, and $\delta_{mn} = 0$ for $m \neq n$. To evaluate the relaxation components, we assume [3] that, due to relaxation, Liouville quantum equation describes a complete chain of equations, the transition rate ν_{mn} between the spin states ψ_m and ψ_n being a function of the imaginary quantities iH_{mn} and $-iH_{mn}$. We suppose also, that the component representation of the relaxation operator is structurally similar to that of the Liouville operator, with real ν_{mn} substituted for $\pm iH_{mn}$. We change likewise from δ_{mn} to the overlap functions p_{mn} in order to allow for the stochastic interaction of the paramagnetic center with its surroundings $\langle\psi_m\psi_n\rangle = p_{mn}$ which is < 1, for $n = m$ or > 0 for $n \neq m$. It should be clear, that $\nu_{mn} \to 0$ and $p_{mn} \to \delta_{mn}$ as the density of active surrounding active spin particles decreases. Thus, the semiempirical relaxation operator is four-index relaxation matrix with real members: $R_{mjkn} = \nu_{mj}p_{kn} + p_{mj}\nu_{kn}$.

IC/PP2888/110: **Monte-Carlo study of transition temperature of Mn-doped GaN diluted magnetic semiconductor.**

Presenter: Jeffrey Rufinus (Widener University, USA)

We have used a large scale Monte Carlo simulation technique to study the effect of metal cluster distribution on the transition temperature of Mn-doped GaN Diluted Magnetic Semiconductors. To calculate the transition temperature via Monte Carlo simulations, a Density functional theory (DFT)-based Locally Self Consistent Multiple Scattering method has been used to determine the coupling between all pairs of metal atoms in the supercell. Here we present the result of this calculation, which shows that metal cluster distribution does affect the calculated transition temperatures of the material.

IC/PP1960/113: **Cycle-to-cycle control of simulated moving bed processes.**

Presenter: Cristian Grossmann (ETH Zürich, Switzerland)
Co-author: Mohammad Amanullah (ETH Zürich, Switzerland)
Co-author: Marco Mazzotti (ETH Zürich, Switzerland)
Co-author: Massimo Morbidelli (ETH Zürich, Switzerland)
Co-author: Manfred Morari (ETH Zürich, Switzerland)

Simulated moving bed (SMB) is a continuous chromatographic separation technique that offers high productivity and low solvent consumption. SMB has gained importance in the pharmaceutical and fine chemical industry to perform difficult separation tasks, like purification of chiral molecules for single enantiomer drug development. However, an automatic control algorithm for SMB units that guarantees an optimal, robust operation is still an open and challenging problem because of the complex dynamics involved in this process; e.g., its cyclic and hybrid nature of inlet/outlet port switching, with nonlinearities and delays.

We have developed a control scheme that integrates both, the optimization and control of the SMB unit. The control problem is formulated as a constrained dynamic optimization problem within the repetitive model predictive control framework. The controller predicts and optimizes the future inputs over a given horizon of time by making use of a linear time-invariant cycle to cycle SMB model derived from the system of PDEs describing the process. This scheme is implemented according to a receding horizon strategy; i.e., a new optimization problem based on the latest estimate of the plant state is solved as new measurements are available. The state estimate is computed using a linear Kalman filter. This approach provides the flexibility to apply the controller to a wide range of separation tasks, regardless of the type of isotherm characterizing the mixture or the operation mode of the SMB unit, i.e. synchronized or asynchronized switching of the ports.

This work presents the mathematical development of the cycle to cycle controller. Its performance is illustrated through simulations and experiments that show how the controller fulfills the product and process specifications while operating the SMB unit optimally, regardless of the uncertainties in the parameters of the system or the disturbances.

12: Bio-Mathematics, Minisymposia

IC/MP243/012: Computational methods and investigations in cardiac modeling.

Organiser: Jacques Beaumont (Binghamton University, USA)

Being the number one killer in most industrialized countries, death due to cardiac arrhythmias constitutes a health problem of considerable extent. Over an average life time the human heart beats about 3×10^9 times. Beat after beat the heart performs its function despite numerous disturbances. However, although robust to most perturbations, the heart remains fragile to specific ones. For example several mutations in genes encoding cardiac proteins produce relatively small changes in membrane current kinetics still such minor changes can generate fatal arrhythmias. Also puzzling is the individual variability. For a number of years life science scientists have been puzzled by the fact that the first manifestation of an electrical disturbance occurring in a context of coronary artery disease is fatal to some individuals but not to others. Understanding the source of such sensitivity as well as the individual variability is very much at the basis of developing better interventions. Over the years it has become clear that: the detailed cell membrane current kinetics, the large scale of the system, its complex anisotropy, and convoluted geometry play equally important roles in the setting of arrhythmias. Due to the multifactorial/multiscale nature of the mechanisms of arrhythmias it is not possible to progress on this problem solely on the basis of experimentation. Along this line of thinking, this symposium presents mathematical and computational methods that allow to cope with the multifactorial/multiscale nature of this problem. Furthermore the speakers present several investigations where an elaborate methodology is applied to elucidate the mechanisms of arrhythmias. Overall the symposium material constitutes mathematical approaches allowing to capitalize on the genome, and various cardiac imaging modalities in our venture to develop better therapeutic interventions.

Inversion of Markov processes in bioelectricity: implications for cardiac modelling. **Jacques Beaumont** (Binghamton University, USA), Nikolauss Szeverenyi (Upstate Medical University, USA), David Feiglin (Upstate Medical University, USA) IC/MT275/012

We address the problem associated with the estimation of the voltage dependent transition rates $\vec{\alpha}(u)$ of Markov models utilized in the description of channel gating. We cast this problem in a computational framework aiming at elucidating the mechanisms of life threatening arrhythmias in the entire heart.

Simulation of electric conduction is carried out with a pair of reaction diffusion equations (Bidomain) coupled through their source term with ordinary differential equations (ODEs). These ODEs are mainly composed of Markov models of channel gating. This formalism being empirical, $\vec{\alpha}(u)$ are estimated from experimental data collected in isolated cells (voltage clamp data). The experimental data being the solution of the Markov model in simple conditions, this is clearly an inverse problem. Assuming $\vec{\alpha}(u)$ parameterized with a linear combination of cubic B-splines, we present an inversion method permitting to obtain the coefficients of the expansion through recurrent matrix operations. Considering voltage clamp data sets generated with experimental protocols commonly employed in electrophysiology, our inversion method shows that the Markov gating model is not sufficiently constrained. However the number of inversion solutions is finite, and can be determined systematically.

We assess the implications of the non-uniqueness of the inverse solution of Markov gating models in the simulation of scroll waves anchoring, which is an important mechanism of arrhythmias. Considering multiple inverse solutions lead to a wide range of predictions regarding the interval of time a scroll wave remains anchored. Based on our inversion method we discuss ways to generate voltage clamp data sets that could fully constrain Markov models of channel gating. The availability of such data could dramatically improve the accuracy of the predictions of large scale simulations of electric conduction in the heart.

Simulations of normal and reentry dynamics with mono-domain and bi-domain cardiac models. **Luca Pavarino** (Università degli Studi di Milano, Italy), Piero Colli Franzone (Università degli Studi di Pavia, Italy), Bruno Taccardi (University of Utah, USA), Simone Scacchi (Università degli Studi di Pavia, Italy) IC/MT301/012

We present the results of large-scale parallel simulations obtained integrating two advanced multiscale models in electrocardiology, the anisotropic Bidomain model of cardiac tissue, a degenerate system of two parabolic reaction-diffusion equations, and the Luo-Rudy ionic model, a system of several ordinary differential equations. The simpler anisotropic Monodomain model is also considered. The resulting coupled model includes orthotropic anisotropy, transmural fiber rotation and homogeneous or heterogeneous intrinsic membrane properties, due either to the presence of midwall cells (M-cells) with different APDs or to the presence of subendocardial ischemic regions. Various dynamical features of the model are investigated, for both normal and reentry dynamics, yielding detailed results on recovery and APD dispersions.

Orthotropic and heterogeneous models of the cardiac bioelectric activity. **Piero Colli Franzone** (Università degli Studi di Pavia, Italy), Luca Pavarino (Università degli Studi di Milano, Italy), Simone Scacchi (Università degli Studi di Pavia, Italy), Bruno Taccardi (University of Utah, USA) IC/MT313/012

We consider a mathematical model on a periodic cellular assembling of the tissue and we derive a macroscopic model called *bidomain* using tools of Γ-convergence theory. The *bidomain* model consists in a degenerate reaction-diffusion system coupled with an ordinary differential system and their simulation in 3-dimensional geometry with twisted anisotropy exhibits considerable numerical difficulties and complexity in order to cover the entire range of cardiac electrodynamics behavior. We briefly describe some relaxed approaches: the anisotropic geometric evolution laws capturing the motion of the excitation wavefronts and the anisotropic *monodomain* models. We introduce a splitting of the cardiac current sources which provides a tool for the explanation of the potential patterns and of the multiple waves appearing in the electrograms. We discuss the combined effect of i) the anisotropic electrical conduction, ii) the fiber rotation and iii) heterogeneous intrinsic properties of the cell membrane on the excitation spreading, the potential maps and electrograms elicited by a local stimulus.

Simulating the initiation and control of re-entrant arrhythmias in human virtual ventricles. **Arun Holden** (University of Leeds, UK) IC/MT3297/012

An electrophysiological virtual cardiac tissue is an anatomically (size, geometry, fibre orientation and sheet structure) and spatially heterogeneous, biophysically (kinetics of membrane ion channels, pumps and exchangers, and intracellular ion binding and sequestration) detailed computational model. It is in the form of a reaction diffusion partial differential equation. The reaction term is stiff, high order and exhibits threshold behaviours, and is obtained from voltage clamp experiments on single cells and ion channels in isolated membrane patches. The diffusion term is a tensor describing anisotropy and orthotropy in propagation that results from the fibre orientation and sheet structure of the ventricular wall, that is obtained from quantitative histology or diffusion tensor magnetic resonance imaging. We have constructed such a virtual tissue for the electrophysiology of the human ventricles, and use it to evaluate, and dissect in space and time, candidate mechanisms for the initiation and control of arrhythmias, ventricular tachycardias and fibrillation. In both of these life threatening arrhythmias re-entrant propagation occurs in which the same excitation wavefront repeatedly invades the same piece of tissue. In simple excitable media models re-entry is caricatured by spiral waves in 2D, and scroll waves in 3D. Using high performance computing we simulate the initiation, evolution and termination of ventricular fibrillation in the normal and modified (inherited channelopathies, effects of antiarrhythmics) ventricular wall.

Work done in collaboration with Drs. Oleg Aslanidi (Manchester), Alan Benson (Leeds) and Richard Clayton (Sheffield).

IC/MP28/010: Stochastic aspects of bifurcation and multi-stability in gene regulation.

Organiser: Wilhelm Huisinga (National University of Ireland, Maynooth)
Co-organiser: Michael Mackey (McGill University, Canada)

Modelling and simulation has become the focus of the pharmaceutical industry, driven by the emerging consensus that *in silico* predictions, combined with *in vitro* data, have the potential to significantly increase insight into physiological processes and their pharmacological modification. Studying cellular processes involved in a drug's effect at the target site are of particular interest due to large attrition rates in the clinical trail phases of drug certification. The effect of a drug depends on its potency to qualitatively alter the cellular system or pathways involved. Identification, analysis and understanding of the dynamic switching behavior and bifurcation pattern of cellular processes are therefore of major interest.

This minisymposium focusses on mathematical techniques to identify, analyse and understand multistability and qualitative switching of cellular processes. It aims to bring together mathematical approaches based on deterministic as well as stochastic models, focussing both on the modelling approaches and the techniques suitable to analyse those models.

Stochasticity and designs of genetic networks. **Peter Swain** (McGill University, Canada) IC/MT2600/010

Biochemical reactions are significantly stochastic. Stochasticity has been quantified by using fluorescent reporters in both bacteria and simple eukaryotes. Given its magnitude in vivo, it is at first puzzling how cells reliably process information: how can a signalling network, whose components have concentrations that fluctuate in an unpredictable manner, generate predictable cellular behaviour? I will propose two network designs that aid information processing and flow in biochemical networks. The first, translational feedback, efficiently controls intrinsic noise in network components. The second is a genetic network that enables a cell to classify the state of its environment from intracellular concentrations despite extrinsic noise. Finally, I will highlight an experimental technique that harnesses intrinsic noise to quantify numbers of fluorescently tagged proteins.

Origin of bistability in the lac *operon.* **Moisés Santillán** (Unidad Monterrey, Mexico), Michael Mackey (McGill University, Canada), Eduardo Zeron (Unidad Monterrey, Mexico) IC/MT1021/010

Multistability is an emergent dynamic property that has been invoked to explain multiple co-existing biological states. In this, work we investigate the origin of bistability in the *lac* operon. To do this, we develop a mathematical model for the regulatory pathway in this system and compare the model predictions with the experimental results of Ozbudak *et al.* (*Nature* 427, 737-740, 2004), in which a non-metabolizable inducer was employed. We investigate the effect of lactose metabolism using this model, and show that it greatly modifies the bistable region in the external lactose (Le) *vs.* external glucose (Ge) parameter space. The model also predicts that lactose metabolism can cause bistability to disappear for very low Ge. We have also carried out stochastic numerical simulations of the model, for several values of Ge and Le, to analyze the effects of intrinsic noise due to small numbers of regulatory molecules. Our results indicate that bistability is an efficient way to guarantee that *E. coli* consumes glucose and lactose in the most efficient possible way. Namely, the *lac* operon is induced only when there is almost no glucose in the growing medium, but if Le is high, the operon induction level increases abruptly when the bacterial culture is virtually depleted of glucose. We demonstrate that this behavior could not be obtained without bistability if the stability of the induced and uninduced states is to be preserved. Finally, possibility of using the present methods and results to study the emergence of multistability in biological systems other than the *lac* operon.

Near-critical fluctuations in pathways with coupled flux. **Johan Elf** (Harvard University, USA) IC/MT1486/010

I will discuss the near-critical properties of unsaturated multi-substrate reactions [1,2]. In essence, one substrate pool can decrease while another increases, such that the overall flux remains unchanged. This results in high sensitivity in substrate concentrations to flow imbalances, but it also induces large zero order fluctuations in several dimensions. The near-critical properties of coupled flow processes are predicted to have important consequences for the flow of different amino acids into proteins synthesis [3]. In particular I will discuss the implication for transcriptional control of amino acid biosynthetic operons.

If there is time I will also discuss noise induced domain separation in spatially extended bi-stabile systems [4].

Discrete methods for the qualitative modeling of regulation networks. **Ron Pinter** (Technion – Israel Institute of Technology) IC/MT2999/010

Modeling and analysis of genetic regulatory networks is essential both for better understanding their behavior as well as for elucidating and refining open issues. To this end, a model needs to effectively reflect important qualitative characteristics such as transient expression, robustness, and sensitivity to initial conditions. We describe discrete computational models that allow for such qualitative analyses of regulatory pathways in an effective manner without the need for detailed quantitative data.

Our primary computational tools are discrete transition systems. A system's next state is determined by a set of simple transition rules that reflect both the interactions that govern regulation as well as the conjunctive conditions that enable them. The synchronous application of the transition rules — first to an initial vector and then repeatedly onwards — constitutes a simulation of the system's behavior. We used a variety of techniques, including Karnaugh-like maps, to analyze the functional relation between the initial states and their type of behavior.

We have applied our methods to analyze the transience and robustness of several representative developmental pathways, *e.g.* the transcription of meiosis-specific genes in budding yeast; our simulations suggested a new mode for the negative feedback regulation in this system, which was verified experimentally. In general, our methods provide insights into how to distinguish among and reason about alternative hypotheses concerning the function and structure of regulatory networks.

IC/MP210/010: Emerging challenges in mathematical biology.

Organiser: David Kinderlehrer (Carnegie Mellon University, USA)
Co-organiser: Emmanuele DiBenedetto (Vanderbilt University, USA)
Co-organiser: Angela Stevens (Universität Heidelberg, Germany)

The synergy between the Life Sciences and mathematics is growing rapidly. Mathematics and Biomedical Sciences will reach soon a common ground and language as deep and fruitful as that present between Mathematics and Physics, Chemistry, Engineering and Material Sciences.

Further progress in understanding basic functional mechanisms ină biology and medicine, and for models to become more predictive, requires a variety of new mathematical methods, and, mostly, a change of investigative mentality. The goal is generate solid and robust models, which, as for Physics, Chemistry and other disciplines, become cornerstones for future developments.

With this in mind, the mini symposium on mathematical biology asks of mathematicians andă experimentalists to present contributions, blending experimental and mathematical challenges in the life-sciences.

Mechanics of biological materials making tendons and ligaments. **Antonio Fasano** (Università di Firenze, Italy) IC/MT1184/010

The material making ligaments and tendons is characterized by a threshold for extensibility, which makes its response to traction nonlinear. Such a behaviour can be described, in the one-dimensional case, by a nonlinear relationship between stress and strain with the stress going to infinity when the strain approaches the threshold. An extrapolation of such a law is considered in which the material is simply linear elastic below the threshold and becomes inextensible at the maximum admissible strain. In this case the transition is also marked by a stress threshold. The corresponding constitutive law has an implicit form. A specific model problem is studied for a layer in which one boundary is kept fixedd, while the other is subject to a shear stress exceeding the threshold value. Two questions are addressed: (i) The mathematical formulation of the corresponding free boundary problem and the existence of solutions, (ii) Whether or not the problem with the implicit constitutive law can be recovered as a limit from the explicit nonlinear elastic formulation. Not surprisingly the mathematical problem takes the form of a free boundary problem for the wave equation, but the conditions at the moving interface can be considerably complicated and have different aspects for subsonic and for supersonic interfaces. Existence and uniqueness are proved for the subsonic case, which however turns out to be of moderate physical interest. The supersonic case is closer to physics, but so complicated that it is left basically open, with the exception of some typical problems, which are solved explicitly. The comparison between the implicit and the explicit model goes through energy considerations. The implicit model can be dissipative, while the explicit model is not (the dissipation rate can be calculated). So the former cannot be the limit of the latter.

Modeling signal transduction through thrombin receptors in endothelial cells. **Heidi Hamm** (Vanderbilt University, USA) IC/MT3180/010

Stimulation of many G protein coupled receptors (GPCR) results in the activation of multiple classes of G proteins. How these individual pathways form interconnected networks modulating each other in a spatio-temporal manner and ultimately integrate to form a single combined response has been largely overlooked by both the biological and mathematical communities. We have developed techniques in our laboratory which allow us to specifically investigate the biochemistry of individual G protein systems induced by promiscuous GPCR. We are connecting these experimental approaches with mathematical modeling of the spatio-temporal aspects of signaling through the thrombin receptor which governs permeability in the endothelium. On endothelial cells, thrombinŠs effects are mediated mainly through activation of PAR-1 by cleaving the amino terminal domain of the receptor, exposing a new terminus. Three classes of G proteins, Gai, Gaq, and Ga12/13, have been shown to by activated by PAR-1. Importantly, each class of G proteins have been shown to be involved in thrombin-induced permeability. Our modeling efforts have shown that this receptor takes on different affinity for the three G proteins based on how it is activated. Thrombin receptor agonist peptides activate PAR-1 in such a way as to enhance $G\alpha q$ signaling pathways, increasing calcium mobilization, and/or decrease $G\alpha 12/13$ signaling pathways leading to endothelial barrier dysfunction.

Variability of the single-photon response in photo-transduction. **Emmanuele DiBenedetto** (Vanderbilt University, USA), Daniele Andreucci (Università degli Studi di Roma "La Sapienza", Italy), Paolo Bisegna (Università degli Studi di Roma Tor Vergata, Italy), Giovanni Caruso (Università degli Studi di Roma Tor Vergata, Italy), Heidi Hamm (Vanderbilt University, USA), Lixin Shen (Vanderbilt University, USA) IC/MT1763/010

The rod outer segment (ROS) in vertebrates consists of a cylinder including a stack of thin discs carrying photoreceptors. The second messengers Calcium and cGMP diffuse in the cytosol, which is the layered domain formed by the ROS from which the discs are ideally removed.

Upon activation the Rhodopsin photoreceptors starts a cascade (receptor-transducer-effector) and undergoes a number of phosphorylation events random in duration, prior quenching at a random shutoff time. The final output is the photocurrent generated by closing of the cGMP-gated channels.

Because of the presence of several random events in the cascade, and in analogy with similar physical processes exhibiting random shutoff times, such as radioactive decay, one might expect that he final output is highly variable (large CV=coefficient of variability).

It is however observed that the CV of the photocurrent at peak time is relatively low.

We explore some reasons for such a low variability, by separating the random effects of the Rhodopsin shutoff events, from the diffusing/stabilizing effects of the second messengers in the cytoplasm

Equation vs. chip: integrative and iterative studies of cell signaling. **Andre Levchenko** (Johns Hopkins University, USA) IC/MT1204/010

Living cells have evolved complex and sophisticated means of detecting and responding to changes in their microenvironment. Loss of the ability to correctly detect and interpret these changes might result in severe disorders, including cancer. Our lab has been engaged in the analysis of cell signaling and cell-cell communication using novel mathematical, computational and experimental tools, including performing experiments with live cells in micro- and nano- fluidic chips. In this talk I will discuss the the recent progress in our analysis of how signaling pathways are organized and how the underlying chemistry supports efficient and robust information transfer.

IC/MP210/010: Emerging challenges in mathematical biology. #2

(For abstract, see session #1 above.)

Aspects of modeling transport in small systems with a look at motor proteins. **David Kinderlehrer** (Carnegie Mellon University, USA), Michel Chipot (Universität Zürich, Switzerland), Stuart Hastings (University of Pittsburgh, USA), Michał Kowalczyk (Universidad de Chile), Bryce McLeod (University of Pittsburgh, USA) IC/MT1233/010

Motion in small live systems has many challenges. Prominent environmental conditions are high viscosity and warmth. It is difficult to move and maintaining a course is compromised by immersion in a highly fluctuating bath. We discuss some possibilities for motor proteins, which transduce chemical energy into directed mechanical energy. Such nanoscale motors, like conventional kinesin, have a role in intracellular transport, separating the mitotic spindle, and many other cellular functions. Our approach is to formulate a dissipation principle connected to the Monge-Kantorovich mass transfer problem. We show how this leads to a system of evolution equations. We then discuss how various elements of the system must be related in order that transport actually occur.

Multi-scale analysis of systems modelling reactive flow, diffusion and transport through biological membranes and tissue. **Willi Jaeger** (Universität Heidelberg, Germany), Maria Neuss-Radu (Universität Heidelberg, Germany), Andro Mikelic (Université Claude Bernard Lyon I, France) IC/MT2313/010

Modelling flow, transport and reactions of substances in membranes and tissues and their interactions with mechanics of the solid structures on a cellular level lead to a coupled system of nonlinear partial differential equations in complex geometric structures. Taking into account biological information from experiments, characteristic scales are identified. The arising non-standard model system is solved and estimates of the solutions are derived, controlling their dependence on the scale parameter. Using techniques of asymptotic analysis, we investigate the limit to a macroscopic model system under the assumption of periodic structures. By coupling information on the processes in the micro-scale with macroscopic properties we provide theoretical answers to questions posed by physiologists studying experimentally the transport through tissues and cell layers. This lecture is based on joint work with M. Neuss-Radu (Heidelberg) and A. Mikelic (Lyon).

A mathematical approach to biological invasive processes. **Gabriela Litcanu** (University Witten/Herdecke, Germany) IC/MT2308/010

The cell proliferation process is normally closely controlled by several feedback biological processes. Despite of this fact, sometimes the cell populations break away from their primary status through mutations that allow them to spread into surrounding medium. This invasion process involves a number of changes in cells behaviour, in particular changes in motility, adhesion and production of enzymes that will manipulate their local environment. An example is tumour invasion, that enables the cancer cells to break down the surrounding tissue and to move into a blood vessel and be transported through the body. This is a very complex process and several authors, during the last decades, have proposed mathematical models for it.

In this talk we shall discuss some aspects related to mathematical models for the cell invasion processes. Among the aspects we intend to focus on, we mention existence results concerning the solutions of the equations involved and asymptotic behaviour of the solutions. We also intend to present numerical results and a comparison with experimental data will be taken into account.

Mathematical modeling of alignment and aggregation in cell biology. **Angela Stevens** (Universität Heidelberg, Germany), Kyungkeun Kang (Sungkyunkwan University, South Korea, Sud-Korea), Benoit Perthame (École Normale Supérieure de Paris, France), Ivano Primi (Max-Planck-Institut Leipzig, Germany), Juan Velazquez (Universidad Complutense de Madrid, Spain) IC/MT1957/010

Self-organization of cells and filaments is an important process in developing and living tissues. Long-range and short-range signaling as well as mechanical interactions play a role here. A question of major interest is, how the dynamics of pattern formation are influenced by the specific type of cellular interaction.

In this talk we focus on structure formation due to cell motion and alignment. Models of integro-differential-equations will be analyzed with respect to their qualitative behavior, in order to undestand the interplay between structure and function in these interacting cell systems.

IC/MP227/015: The impact of biology on mathematical modelling.

Organiser: Robert Anderssen (CSIRO, Australia)
Co-organiser: Frank de Hoog (CSIRO, Australia)

The role played by mathematics in solving challenging real-world problems is clearly understood. One can find many examples in industrial mathematics. Impact occurs when the matter under investigation leads to a question which can only be answered after further development of new mathematical results.

This process of letting the application dictate how the underlying mathematical models should be formulated, so familiar in industrial mathematical contexts, will play an equally important role in the intefacing of biology with mathematics. Success will depend heavily on collaboration between biologists and mathematicians. The talks in this Minisymposium will explore such matters by first identifying an important biological problem, explaining how mathematics is involved, discuss the essence of this mathematics and finally identify key mathematical questions that need to be resolved in order to advance current understanding.

Modelling the viscoelasticity of cell-shape changes. **Roger Hosking** (Universiti Brunei Darussalam), Saiful Husain (Universiti Brunei Darussalam) IC/MT411/015

Biological processes often involve changes in shape, which may well raise rheological issues. For example, cell deformation occurs in response to forces from the external environment or from within the cell. In tests of cell rheology, an external constraint is usually superimposed on an already mechanically active cell, so the measurements may reflect both active and passive viscoelastic deformation. Experiments provide information on cell deformation under stress, such that a constitutive model for the cell structure may emerge. There are deformation phases with various time scales, which are open to interpretation. A simple Kelvin viscoelastic model has been suggested, but there are other viewpoints.

Inverse bifurcation analysis for gene networks: application to cell cycle and circadian rhythm models. **James Lu** (RICAM Linz, Austria) IC/MT230/015

The use of mathematical models provides a way to understand the complex interaction of genes regulating the metabolism of living cells. Given ODE models for gene regulatory systems, one may ask the question: how does the qualitative behavior of the regulatory system arise, from parameter choice, network topology, or both? To address such questions we propose the methodology of inverse bifurcation analysis, based on mapping the space of bifurcation diagrams back to the space of parameters and networks.

We show that sparsity-promoting regularization strategy, in combination with numerical bifurcation analysis, can be used to identify small sets of "influential" submodules and parameters within a given network. In addition, hierarchical strategies can be used to generate parameter solutions of increasing non-zero components. We demonstrate the proposed method in addressing some biological questions arising from models of cell cycle and circadian rhythm.

An inverse problems approach to the identification of the chemotaxis response function. **Philipp Kuegler** (RICAM Linz, Austria) IC/MT367/015

Chemotaxis is the directed motion of cells in response to the gradient of a chemical attractant. Modeling of the cell flux due to chemotaxis typically involves a chemotaxis response function depending on the attractant concentration. However, different ideas about its functional form can be found in the literature. In this talk we consider the determination of the functional form of the chemotaxis response as a nonlinear inverse problem. We discuss Tikhonov regularization for its solution and present numerical results both for simulated and experimental cell density data.

Approximate solutions of differential equations in biosensors models. **Frank de Hoog** (CSIRO, Australia) IC/MT1603/015

The response of biosensors can be modeled using an electrical network with a number of switches, where their density can be modeled as the solution of a system of differential equations. However, while there is no difficulty in obtaining numerical solutions to these differential equations, it is often difficult to interpret the results of these simulations. This talk will focus on obtaining an improved understanding of the maximal rate of response. Specifically, for typical biosensor parameters:

- A number of simplifications to the underlying system of ordinary differential equations are derived
- A simple algebraic expression for the maximal rate of response when the analyte concentration is high is derived
- A simple algebraic expression for the maximal rate of response when the analyte concentration is low is derived
- A simple algebraic expression for the maximal rate of response, which is valid in an asymptotic sense for the complete range of analyte concentrations of interest is derived

This is an illustration of how an important industrial biology problem has impacted on the mathematics that models the essence of the process under investigation.

IC/MP227/015: The impact of biology on mathematical modelling. #2

Organiser: Robert Anderssen (CSIRO, Australia)
Co-organiser: Frank de Hoog (CSIRO, Australia)

(For abstract, see session #1 above.)

The EM algorithm for PET: a regularization approach. **Elena Resmerita** (RICAM Linz, Austria), Robert Anderssen (CSIRO, Australia) IC/MT2294/015

Positron emission tomography (PET) is a powerful technique for assessing physiological parameters such as blood flow and metabolism, based on measuring concentration of radiotracers. The EM algorithm for image reconstruction in PET has a simple form, being frequently used in practice. In this presentation, we consider the algorithm in an infinite dimensional setting and approach it via regularization, which allows us to investigate its convergence and to deal with its instability.

Modelling pattern formation in plants. **Robert Anderssen** (CSIRO, Australia) IC/MT1397/015

The history of studying pattern formation in biology can be traced back to Fibonacci and phyllotaxis. Though much has been written on this subject, the mechanism of the genetic control of the geometry of pattern formation in plants, such as the spacing of trichomes on Arabidopsis leaves, remains an open question. From a macroscopic perspective, Turing's seminal 1952 paper on morphogenesis represents the starting point for the various partial differential equation, reactor-diffusion, models that have been proposed for pattern formation in biology. Though such models can be adapted to simulate observed biological patterns, the activator-inhibitor mechanisms, on which they are based, have yet to be observed biologically. A new mathematical approach is required which responds to, and explains the role of, the dynamics of the plethora of genes involved in biological development in terms of the results from mutant experiments. A model for the control of the spacing of the trichomes on Arabidopsis leaves will be presented.

Stochastic delay modelling and simulation of cellular signalling and genetic regulation. **André Leier** (University of Queensland, Australia), Kevin Burrage (University of Queensland, Australia), Manuel Barrio (Universidad de Valladolid, Spain) IC/MT4139/015

Time delays associated with slow biochemical processes such as transcription, translation, nuclear and cytoplasmic translocations are known to affect the dynamics of genetic regulation. Temporal models of cellular signalling and genetic regulation have to take these delays into account in order to capture the dynamics more accurately and to allow for more reliable predictions.

Recently, transcriptional and translational delays have been studied and modelled for autoregulated oscillating genes using delay differential equations (DDEs). However, in this modelling regime we assume large numbers of molecules for each species which enables us to talk about concentrations instead of numbers of molecules. The dynamics is deterministic and is not suitable for modelling stochastic effects that are due to small numbers of molecules and the uncertainty of knowing when a reaction occurs and which reaction it is.

In this talk, we discuss stochastic delay modelling and simulation suitable to capture both stochasticity and delay in temporal models of cellular signalling and genetic regulation. Here, we focus on delayed feedback-loops in the genetic regulation of hes1 and her1/her7, genes that are known to play key roles as molecular clocks during somite segmentation in Mouse and Zebrafish.

The use of hydrodynamics to help understand biological hazards in estuaries . **Stephen Roberts** (Australian National University) IC/MT4154/015

We will present our efforts to use hydrodynamic modelling of esturies to better understand the development of biological hazards (nutient overload, leading to toxic blooms, increased pathogen concentrations). We would like to gain an understanding of the correlation of typical hydrodynamic measures such as resident times to the development of biological hazards. A discussion of coupled hydrodynamic, pathogen and nutient models will be presented.

IC/MP222/015: Dynamics of gene regulation.

Organiser: Tomáš Gedeon (Montana State University, USA)
Co-organiser: Konstantin Mischaikow (Rutgers University, USA)

Understanding function and control of gene regulation is at the center of current efforts in molecular and systems biology. The importance of the dynamics of this regulation is evident by the fact that not only do cells and organisms display internal cycles and rhythms, but also live in and therefore must respond to constantly changing environments.

The speakers in this Minisymposium will describe different approaches to modeling the dynamics of associated with gene regulation at a variety of levels and in a variety of organisms.

Mathematical modeling of gene regulation. **Michael Mackey** (McGill University, Canada) IC/MT1607/015

This talk will focus on mathematical models of inducible and repressible operons, and the variety of dynamic behaviours that these gene regulatory networks may display. Concrete examples will be drawn from the lac operon, the tryp operon, the lysis-lysogeny switch in phage lambda, and the developmental oscillations in Hes1 expression.

Dynamics of a simple regulatory switch. **Tomáš Gedeon** (Montana State University, USA), Konstantin Mischaikow (Rutgers University, USA) IC/MT1573/015

We consider the dynamics of a model toggle switch abstracted from the genetic interactions operative in a fungal stress response circuit. The switch transduces an external signal and propagates it forward by mediating the transport between compartments of two interacting gene products. The transport between compartments is assumed to be related to the degree of association between the interacting proteins, a fact for which there exists a wealth of biological evidence. The ubiquity and modularity of this cellular control mechanism warrants a detailed study of the dynamics entailed by various modeling assumptions. Specifically, we consider a general gate model in which both of the associating proteins are freely transportable between compartments. A more restrictive, but biologically supported model, is considered in which only one of the two proteins undergoes transport. Under the strong assumption that the disassociation of the interacting proteins is unidirectional we show that the qualitative dynamics of the two models are similar; that is they both converge to unique periodic orbits. From a biophysical perspective the assumption of unidirectional dissociation is unrealistic. We show that the same result holds for the more restrictive model when one weakens the assumption of unidirectional binding or disassociation. We speculate that this is not true for the more general model. This difference in dynamics may have important biological implications and certainly points to promising avenues of research.

Gene regulation during cell-fate decisions in bacillus subtilis. **Dagmar Iber** (Imperial College London, UK) IC/MT2626/015

Sporulation in *Bacillus subtilis* serves as a paradigm for the development of two different cell types from a single cell. The key event is the selective activation of the transcription factor sigmaF in the smaller prespore but not in the larger mother cell. We have recently developed a comprehensive quantitative model which showed that the difference in volume between the two cell types is sufficient to function as the primary trigger for determining cell fate. The model predicted that this switch depended on the allosteric behaviour of a key protein kinase and on a low rate of dephosphorylation by the corresponding phosphatase; both effects were confirmed experimentally. The same network architecture is employed in the regulation of

the general stress response although the trigger is necessarily very different. With the help of the quantitative model we can explain how such small regulatory network not only achieves an exceptionally high sensitive to input but is also readily adjustable to respond to different types of triggers.

Experimental and modeling approaches for the analysis of the spindle assembly checkpoint. **Andrea Ciliberto** (Istituto FIRC di Oncologia Molecolare, Italy) IC/MT3750/015

The spindle assembly checkpoint (SAC) ensures that the metaphase-to-anaphase transition occurs only when all chromosomes undergo bipolar attachment with the microtubles emanating from the spindle pole bodies. By doing so, the SAC prevents the formation of cells with an uneven number of chromosomes (aneuploidy), a phenomenon known to play an important role in cancer development. Interestingly, the SAC is activated even by a single unattached kinetochore, a fact that suggests the presence of a catalytic step that amplifies the signal originated from unattached kinetochores. Several pieces of this mechanism have been identified in recent year, but still a proper molecular understanding of the process is awaiting. With a combination of experiments in vitro and mathematical modeling, we propose a model for the SAC based on autocatalysis. The molecular network we describe involves a subset of the molecules known to be involved in the SAC; nevertheless it is able to describe in qualitative and quantitative detail the main properties of the SAC.

Work done in collaboration with Andrea Musacchio, Romilde Manzoni, Marco Simonetta, Marina Mapelli.

IC/MP222/015: Dynamics of gene regulation. #2

Organiser: Tomáš Gedeon (Montana State University, USA)
Co-organiser: Konstantin Mischaikow (Rutgers University, USA)

(For abstract, see session #1 above.)

Monotone dynamics in gene regulation. **Hal Smith** (Arizona State University, USA) IC/MT3775/015

Monotone dynamical systems theory has played a prominent role in the analysis of simple models of gene regulatory networks. We will survey this work and presnt new results.

On a system reduction for positive feedback networks. **German Enciso** (Ohio State University, USA), Eduardo Sontag (Rutgers University, USA) IC/MT2773/015

A control-theoretic approach has been introduced by Sontag and Angeli to study positive feedback (monotone) networks, by considering an associated input-output system and studying its steady input response function k(x). In this talk it is illustrated that a one-dimensional reduction of the original system is sometimes possible even if k(x) is not single-valued. An application is given to the case of hysteresis on the input variable.

Molecular seismology: an inverse problem in nano-biology. **Peter Hinow** (Vanderbilt University, USA), Erik Boczko (Vanderbilt University, USA) IC/MT3776/015

An obstruction to progress in modeling the dynamics of regulatory networks has been the lack of quantitative time series data for the many molecular processes that are operative during gene expression. Virtually nothing is understood about the dynamics of transcription factor competition at and around individual promoter sequences and the pervasive modeling assumption has been to invoke quasi-equilibrium based on separation of timescales. In considering the modeling problems posed by the members of the GATA family of transcription factors we were led to develop a single molecule assay strategy that can in principle measure the dynamics of association between an arbitrary ligand such as a protein and an elastic fiber like DNA. The assay is based on the following simple observation: the density profile of an elastic fiber like DNA will change in space and time as ligands associate with it. This observation affords a new direction in single molecule studies provided that density profiles can be measured in space and time. In fact, this is precisely the objective of seismology, where the mathematics of inverse problems have been employed with success. We argue that inverse problems in elastic media can be directly applied to biophysical problems of fiber-ligand association, and demonstrate that robust algorithms exist to perform density reconstruction in the condensed phase.

Why does the positive regulation in bacteriophage λ affect isomerization of the RNAP–DNA complex?. **Kate Patterson** (Montana State University, USA) IC/MT4864/015

Bacteriophage λ is the best studied example of a gene regulation switch. The phage-infected cell can follow the lytic pathway which leads to production of new phages and lysis of the cell. Alternatively, the infected cell can follow the lysogenic pathway, in which the virus establishes stable association with the host. In the last 20 years a number of experiments elucidated gene regulation mechanisms that are behind the choice of alternative states and their maintenance.

The transcription initiation involves two distinct steps; first RNA polymerase binds the promoter to form an unstable, closed complex (this reaction is described by an equilibrium constant K_B); second the closed complex isomerizes to an active, stable open complex (the reaction is described by a forward rate constant k_f). The cooperativity between CI protein and RNA polymerase is accomplished by DNA bound CI increasing the forward rate constant k_f about 10-fold without having any significant effect on K_B.

We use a model due to Santillian and Mackey, which is based on Ackers chemical equilibrium description of the promoter binding by the regulatory factors, to show that the stability of the lysogen will be severely compromised if CI had the 10-fold effect on K_B and no effect on k_f.

We also discuss the underlying reasons for this highly nonlinear and counterintuitive effect.

IC/MP266/015: Computational and statistical methods in cell biology.

Organiser: Erkki Somersalo (Teknillinen Korkeakoulu, Finland)

In this minisymposium we discuss numerical and statistical methods applied to problems arising in systems biological models for cell metabolism. The biochemical pathways in different cell types constitute a complex system that depends on a large number of parameters that should be estimated from scarce and imprecise data such as biopsies. The problems are severely ill-posed and underdetermined, and it is of crucial importance to import *a priori* information to reduce the degree of underdeterminacy as well as develop efficient model reduction techniques to make the parameter estimation problem feasible. A combination of numerical and statistical methods is needed to this task. In the minisymposium, recent developments in this area is precented.

Bayesian flux balance analysis. **Knarik Tunyan** (Teknillinen Korkeakoulu, Finland), Jenni Heino (Teknillinen Korkeakoulu, Finland), Daniela Calvetti (Case Western Reserve University, USA), Erkki Somersalo (Teknillinen Korkeakoulu, Finland) IC/MT1218/015

One of the challenging questions in the last decade is to understand the metabolism of the living organisms, i.e., the complex biochemical structure and functions within an organ, as well as relation between different organs. This problem can be formulated as an estimation of the reaction and transport fluxes, when the biochemistry within an organ is known and bound constraints for the fluxes are given. The problem has been addressed previously by a number of authors, and different approaches have been proposed. The steady state condition, when the system under consideration is at rest, can be described by underdetermined system of linear equations with boundary constraints, whereas the dynamics of biochemical reactions and transport processes of metabolism can be represented as a system of ordinary differential equations. Both cases involve a large number of parameters.

The computed solution depends on the input data, which may contaminated by measurement errors and/or fluctuate over a population. Thus, the determination of a unique set of model parameters in both steady state and dynamic cases, based on uncertain data, is usually not possible. Our approach to this problem allows the incorporation of various levels of uncertain information into the model.

The base of our analysis is Bayesian statistical approach and the Markov Chain Monte Carlo techniques. We show that the Bayesian framework can be applied to the flux balance analysis, and the available data can be incorporated into the model by proper construction of the prior densities.

We also address the questions about how the given organ behaves under different conditions, such as physical exercise, diabetic conditions, hypoxia and ischemia.

The obtained solutions are compared with the existing approaches.

Inverse eigenvalue analysis of eukaryotic GATA transcription factor system. **James Lu** (RICAM Linz, Austria), Rainer Machné (Universität Wien, Austria) IC/MT2417/015

Transcription factors can form auto-regulatory feedback cycles by modulating their own expression. By both experimental and theoretical analysis, auto-activating feedback systems have been observed to exhibit bistable behavior. Similar feedback loops, involving both activating and repressing transcription factors, are thought to underly central cellular oscillatory behavior (including the cell division cycle).

In this work, we investigate the possibility for the emergence of new dynamical behaviors through plausible evolutionary transition scenarios for the eukaryotic GATA transcription factor system. This system is known to function as a bistable gene switch and is suspected to be a central regulatory motif in cell-wide oscillatory phenomena. The biologically important questions include: how does the proposed simple evolutionary transition affect bistability? Can oscillations arise from a bistable switch by gene duplications and simple mutations? We propose an inverse method based on sparsity-promoting regularization to computationally investigate these issues.

Dynamic Bayesian sensitivity analysis in myocardial metabolism. **Rachael Hageman** (Case Western Reserve University, USA), Daniela Calvetti (Case Western Reserve University, USA) IC/MT3222/015

The dynamics of biochemical reactions and transport processes in the myocardial metabolism is described by a three-compartment model specified by a large number of parameters. The temporal behavior of some of these reactions and processes during ischemia is not well understood. The available data for the dynamic response of the system during ischemia is scarce and by its own nature statistically distributed. In particular, the distribution of enzyme facilitators $FADH_2$, FAD, NAD+, NADH, ATP and ADP between cytosol and mitochondria are difficult to measure and compartmentalize. We use integrated numerical and statistical techniques to study the sensitivity of the redox and phosphorylation states in both cytosol and mitochondria to the malate-aspartate shuttle and processes including glycolysis, oxidative phosphorylation, lactate production and the transport of chemical species between compartments.

Simulating intercellular calcium and inositol-1,4,5-trisphosphate *signaling in systems of epithelial cells using multiblock grids.* **Petri Fast** (Lawrence Livermore National Laboratory, USA) IC/MT3387/015

We model the biochemical wave dynamics of calcium mediated by inositol 1,4,5-trisphosphate(IP3) in connected epithelial cells. We present a new computational framework that allows for the first time fully three dimensional simulations of the interplay between calcium dynamics, IP3 and calcium buffering species in coupled *in silico* cells represented by structured multiblock grids. Intercellular connections between epithelial cells are modelled using a geometrically realistic computational mesh with a simple continuum description of gap-junctions permeable to IP3. Practical grid generation techniques are discussed for cuboidal epithelial cells consisting of a single layer of three dimensional coupled prismatic domains, each with an arbitrary polygonal top (apical) surface. A novel numerical scheme is presented for modeling diffusion on structured multiblock grids with "gap-junction boundary conditions," where the normal flux across a membrane separating two cells is proportional to a jump in the local concentration. We present results illustrating the range of biological phenomena accessible to these simulation techniques.

IC/MP267/121: Multi-strain diseases: from predictive modeling to vaccine control.

Organiser: Lora Billings (Montclair State University, USA)
Co-organiser: Ira Schwartz (U.S. Naval Research Laboratory)
Co-organiser: Derek Cummings (Johns Hopkins University, USA)

As we become more sophisticated in our resources to fight viral disease, pathogens have shown an exceptional ability to adapt to overcome our attempts to defeat them. From influenza to dengue to pneumoccocus, pathogens have utilized genetic diversity and mutability to escape human's immune defenses. The persistence of influenza depends on its ability to evolve into new strains and subtypes, keeping ahead of natural and vaccine derived immunity. In dengue, antibody-dependent enhancement increases viral replication in the presence of pre-existing immunity, possibly increasing the infectiousness of second infections. This mini-symposium will bring together mathematical researchers, biologists, and epidemiologists to discuss the development of mathematical methods to model the dynamics multi-strain diseases. Using these models, vaccination strategies can be formulated, tested and evaluated in a wide variety of circumstances. Mathematical methods and techniques for analysis and vaccine control will be highlighted along with the models.

The interplay between protective and disease enhancing immunity in the temporal dynamics of dengue. **Derek Cummings** (Johns Hopkins University, USA) IC/MT2704/121

Dengue fever is caused by a mosquito-borne virus of the flavivirus family. The virus causes substantial morbidity and mortality around the globe. Four antigenically distinct serotypes exist. All four circulate in most endemic areas. Sequential infections with multiple serotypes are associated with severe disease -particularly the hemorrhagic form of dengue infections, dengue hemorrhagic fever (DHF) through an immune mediated mechanism. Though immunity is associated with severe disease, it is clear immunity also provides protection from infection under different circumstances. The interplay between protective and disease enhancing immunity is not understood especially at a population level. Four types of immune response are potentially important for dengue; long-term serotype specific immunity, short-term cross-serotype immunity, immune enhancement of secondary infection and dengue-specific, long-term cross-serotype immunity. In this work, I explore the effect of different host/pathogen interactions on population level dynamics of disease incidence using both deterministic and stochastic models. Model outcomes include phase relationships between each of the serotypes and the periodic behavior of different model systems. Simulation results are compared to data from Thailand where all four serotypes of the disease co-circulate.

Why do virulent lineages of bacterial pathogens persist?. **Sunetra Gupta** (University of Oxford, UK) IC/MT2301/121

Populations of pathogenic bacteria commonly contain *lineages* or groups of related organisms, typically defined by non-random associations of alleles at loci which encode housekeeping functions. The presence of these lineages cannot be ascribed to asexual reproduction as many of these pathogens undergo frequent genetic exchange. Rapid clonal expansion can explain the short term domination of a recombining population by a limited number of lineages, but it cannot account for their persistence. Here we propose a theoretical framework which explains both the persistence of lineages in recombining populations and the association of some of these lineages with a propensity to cause disease without invoking a link between mechanisms of transmission and disease.

Desynchronization and spatial effects in multi-strain diseases. **Leah Shaw** (U.S. Naval Research Laboratory), Lora Billings (Montclair State University, USA), Ira Schwartz (U.S. Naval Research Laboratory), Derek Cummings (Johns Hopkins University, USA) IC/MT2655/121

Dengue fever, a multistrain disease, has four distinct coexisting serotypes. The serotypes interact by antibody-dependent enhancement (ADE), in which infection with a single serotype is asymptomatic, but contact with a second serotype leads to serious illness accompanied by greater infectivity. It has been observed from serotype data that outbreaks of the four serotypes occur asynchronously (Nisalak et al., Am. J. Trop. Med. Hyg. 68: 192). We present a compartmental model for multiple serotypes with ADE, and consider autonomous, seasonally driven, and stochastic versions of the model. For sufficiently small ADE, we find that the number of infectives of each serotype synchronizes, with outbreaks occurring in phase. However, when the ADE increases past a threshold, the system becomes chaotic, and infectives of each serotype desynchronize. Certain primary and secondary infective compartments remain synchronized in the chaotic regime, a result which is explained by our analysis and which may be useful for disease monitoring. Spatial effects are included via coupled patch models. We observe desynchronization between spatially distinct regions.

Incorporating realistic genetics in simple models of multi-strain pathogens. **Neil Ferguson** (Imperial College London, UK) IC/MT2431/121

Modelling the transmission dynamics of antigenically variable pathogens poses a key challenge: the exponentially growing dimensionality of the dynamical equations as the number of strains being modelled increases. To avoid this problem, most past deterministic modelling of multi-strain pathogens has made highly simplifying assumptions. Another approach has been to use individually-based microsimulations which explicitly track all members of the host population and their infection history. This has been highly successful at reproducing observed patterns of antigenic evolution of human influenza viruses and giving insight into the immunological mechanisms driving those evolutionary patterns. However, simulation models are far from transparent, so it would be advantageous to be able to bridge the gulf between simple deterministic models and simulations. In pursuit of this goal, we have developed a new set of deterministic multi-strain models with genetic structure in which cross-immunity is determined (in an arbitrary manner) by the degree of genetic overlap between past strains and the new challenge strain. In addition we have incorporated stochastic elements within the model Ü in modelling mutation as the random introduction of new strains, and by modelling extinction as the elimination of a strain when its prevalence drops below 1 infected person. We show that allowing for mutation and extinction reduces strain diversity compared with deterministic models, with a strain carrying capacity set by cross-immunity and population size. The new model confirms the earlier results of simulations that reproducing influenza evolution requires models to incorporate a transient strain-transcending immunity. We also show that such models are able to reproduce the antigenic clustering of strains reported in recent work on the antigenic mapping of influenza.

IC/MP668/121: Mathematical modelling of malaria and other vector-borne diseases.

Organiser: Nakul Chitnis (Swiss Tropical Institute, Switzerland)
Co-organiser: Melissa Penny (Swiss Tropical Institute and Universität Basel, Switzerland)

Vector-borne diseases, such as malaria and dengue fever, kill over a million people per year. The mathematical modelling of vector-borne diseases began in 1911 with Ronald Ross's basic compartmental-model, calculating a stability index to measure the level of malaria transmission. Since then, numerous mathematical models of disease transmission and immunology have been developed and analysed to assist the development and implementation of medicines, vaccines, and intervention strategies. In this minisymposium, we present a history of these models, what the current status of vector-borne disease modelling is, and where modelling can provide useful information to the medical and public health community. We examine some current efforts to model the dynamics of the malaria parasite within the human host, including the development of human immunity and the parasite's dynamics to evade immunity. We present a model of the mosquito feeding cycle that includes the effects of various intervention strategies that either reduce the mosquito-biting rate on humans or kill mosquitoes. We finally present a model of the interaction between malaria prevalence and the evolution of sickle-cell anaemia. These mathematical models provide us with a better understanding of disease dynamics, and can serve as important tools in helping to reduce disease morbidity and mortality.

Mathematical modeling of vector-borne diseases with applications to malaria and dengue fever. **James Hyman** (Los Alamos National Laboratory, USA), Gerardo Chowell (Los Alamos National Laboratory, USA), Nakul Chitnis (Swiss Tropical Institute, Switzerland) IC/MT4136/121

This talk will give an overview of the history, current status, and future directions of mathematical models for vector-borne diseases such as malaria and dengue fever. We describe sensitivity analyses on a mathematical model of disease transmission to determine the relative importance of model parameters to disease transmission and prevalence.

We will apply the models to analyze the impact of climatological variables on the incidences of the disease and will discuss the 2002 dengue epidemic in Colima, Mexico. We estimate the reproduction number from spatial epidemic data at the level of municipalities using a standard dengue epidemic model and assuming pure exponential initial epidemic growth and comparing this estimate fit to a more realistic epidemic model to the initial phase of the dengue epidemic curve. We compute sensitivity indices of the reproductive number (which measures initial disease transmission) and the endemic equilibrium point (which measures disease prevalence) to the parameters at the baseline values. For our malaria model, we find that in areas of low transmission, the reproductive number and the equilibrium fraction of infectious humans are most sensitive to the mosquito biting rate. In areas of high transmission, the reproductive number is again most sensitive to the mosquito biting rate, but the equilibrium fraction of infectious humans is most sensitive to the human recovery rate. This suggests strategies that target the mosquito biting rate (such as the use of insecticide-treated bed nets and indoor residual spraying) and those that target the human recovery rate (such as the prompt diagnosis and treatment of infectious individuals) can be successful in controlling malaria.

A mathematical model of malaria parasite dynamics within host. **Melissa Penny** (Swiss Tropical Institute and Universität Basel, Switzerland) IC/MT1909/121

A discussion and mathematical model of the dynamics of *Plasmodium falciparum* malaria infections within a host will be presented. The parasite's mechanisms of replication, antigenic variation and immune evasion, as well as the host's immune responses will be discussed. A discrete-time, stochastic model capturing these dynamics of an infection will be presented. The model considers current views of *Plasmodium falciparum*'s mechanisms of antigenic variation and captures the recrudescences seen in a typical human infection. The model also allows for drug treatment with the view to evaluate treatment regimes or possible vaccines in larger scale population models. Preliminary results and validation of the model will also be presented.

A mathematical model for the dynamics of malaria in mosquitoes feeding on a heterogeneous host population. **Nakul Chitnis** (Swiss Tropical Institute, Switzerland), Thomas Smith (Swiss Tropical Institute, Switzerland), Richard Steketee (PATH-Europe, France) IC/MT1884/121

We describe and develop a difference equation model for the dynamics of malaria in a mosquito population feeding on, infecting, and getting infected from a heterogeneous population of hosts. Using the force of infection from different classes of humans to mosquitoes as parameters, we evaluate a number of derived parameters, that can be compared to field data, that measure malaria transmission levels. By assigning different types of vector control interventions to different classes of humans, and evaluating the corresponding levels of malaria transmission, we can compare the effectiveness of these interventions. We show a numerical example of the effects of increasing coverage of insecticide-treated bed nets in a human population where the predominant malaria vector is *Anopheles gambiae*.

Coupling ecology and evolution: malaria and the S-gene across time scales. **Zhilan Feng** (Purdue University, USA) IC/MT1915/121

Malaria has long been a scourge to humans. The exceptionally high mortality of malaria in some regions has led to strong selection for resistance, even at the cost of increased risk of potentially fatal red blood cell deformities in some offspring. In particular, genes that confers resistance to malaria when they appear in heterozygous individuals are known to lead to sickle-cell anemia. Thus, there is balancing selection against the evolution of resistance, with the strength of that selection dependent upon malaria prevalence. Over longer time scales, the increased frequency of resistance in a population might be expected to decrease the frequency of malaria and reduce selection for resistance. However, possession of the sickle-cell gene leads to longer-lasting parasitaemia in heterozygote individuals, and therefore the presence of resistance may actually increase infection prevalence. We developed a model that explores the interplay among these processes. By coupling the dynamics of the epidemiology of malaria and the genetics of sickle-cell gene, our model allows for joint investigation of impact of malaria on the selection of S-gene and influence of genetic composition of a population on the maintenance of malaria. Our results are based on threshold conditions derived from the model by separating malaria disease dynamics on the fast time scale and the dynamics of S-gene on the slow time scale and by conducting stability analysis.

IC/MP329/122: Direct and inverse problems in channels and membranes.

Organiser: Martin Burger (Universität Münster, Germany)
Co-organiser: Heinz Engl (RICAM Linz, Austria)
Co-organiser: Robert Eisenberg (Rush Medical University, USA)

Transport through channels and membranes is of fundamental importance for biological function, since it is used to control many processes in health and disease. Various models have been developed in the last years in order to contribute to the understanding of channel function, which is of fundamental importance for controlling diseases and designing channels with specified function. In the mathematical community, this problem has received significant attention very recently, and poses various interesting challenges to modelling, analysis, computation, and, ultimatively requires the solution of inverse problems in order to determine their structure from the (electrophysiological) function.

The aim of this double mini-symposium is to provide an overview of recent developments in direct and inverse problems related to transport through channels and membranes. The first part will start with direct problems (modelling and simulation), while the second part will focus on inverse problems (identification of channel distributions in membranes, identification and optimal design of permanent charges in ion channels).

Inverse problems related to ion channels. **Kattrin Arning** (RICAM Linz, Austria), Lin He (RICAM Linz, Austria), Martin Burger (Universität Münster, Germany), Robert Eisenberg (Rush Medical University, USA), Heinz Engl (RICAM Linz, Austria), Marie Therese Wolfram (Universität Münster, Germany) IC/MT2343/122

Ion channels are proteins with a hole down their middle that allow ions to move across otherwise impermeable cell membranes, thereby controlling many important physiological functions, such as conducting electrical signals down nerve fibres and initiating muscle contraction.

Connecting two baths of fixed ionic concentrations, a single ion channel is immersed in hard-sphere fluid with charged ions. In 2002, Gillespie et al. simplified the movement of the ions to one dimension and described the particle transport as friction-limited drift-diffusion with all excess chemical potentials given by the density functional theory of Rosenfeld (1989, 1993). Furthermore, the applied local electrostatic potential and the fluxes of the different ionic species are modeled through the Poisson-Nernst-Planck (PNP) equations, a system of nonlinear PDEs.

Based on this model we investigate inverse problems related to ion channels. One important feature of the channels is their selectivity property, allowing only certain types of ions to pass. This selectivity is determined by channel structures such as permanent charge, channel geometry and confining potential. Based on measurments of output currents depending on different input voltages and bath concentrations we would like to identify these structural features using a simplified linearized PNP-model. As the underlying operator leads to an ill-posed problem, regularization techniques have to be applied. A second goal appart from the identification of the channel structure is the design of channels that show a desired behaviour such as particular selectivity properties. We also long to achieve this using inverse problems techniques with different regularization methods other than Tikhonov. As the solution of the nonlinear PDEs is quite a high computational effort, fast numerical algorithms will also be considered to speed up the solution of the inverse problem.

Direct and inverse problems in channels and membranes. **Robert Eisenberg** (Rush Medical University, USA) IC/MT2470/122

Channels control the movement of ions and electricity across membranes and cells and thus control an enormous range of biological function. The distribution of channels in different membranes of muscle fibers and the lens of the eye is a classical subject of electrophysiology studied in depth with impedance spectroscopy some decades ago without the benefit of the theory of inverse problems. Attention in the last decades has focused on the properties of channels themselves, particularly once they are open. Ions move through open channels by electrodiffusion and models of charge spheres are quite successful in analyzing and predicting biological function in the few channels studied to date. Extension to the thousands of channels of biological and medical interest requires efficient well designed experimentation because the experiments are so expensive. Solving the mathematical inverse problem of identifying channels will aid enormously. Improving the function of biological channels and building technologically useful channels are important future goals. Naive design will be much less efficient and successul than sophisticated design using the theory of inverse problems.

Density functional theory as a tool to study biological ion channels. **Roland Roth** (Max-Planck-Institut Stuttgart, Germany) IC/MT4792/122

Density functional theory of classical fluids provides a very powerful and general tool to study the free energy and the structure of confined fluids. Using density functional theory it is possible to study the behavior of ion channels, which are membrane spanning proteins.

In this talk a short introduction to density functional theory for a mixture of charged and uncharged spheres is given. We discuss what properties of the system can be calculated and how these calculations can be tested by the help of exact statistical mechanical sum rules. We show how results from relatively simple confining geometries can be generalized to a complex ion channel geometry by the help of the morphometric approach.

Atomic structures of biological transmembrane pores as a basis for simulation of function. **Tilman Schirmer** (Universität Basel, Switzerland) IC/MT1223/000

Bacterial porins allow the passage of solutes across the outer bacterial membrane. Crystal structures show that the scaffold of the pore is a hollow beta-barrel constricted by inwardly folded loops that are forming part of the pore lining. The pore constriction of non-specific OmpF porin is highly charged and shows segregation of basic and acidic residues that face each other across the pore. A multitude of mutations have been analyzed functionally as well as structurally to get insight into the role of this peculiar charge constellation. Brownian dynamics simulations of ion translocation show good agreement with experimental cation/anion selectivity and relative single channel conductance[1]. The simulations reveal distinct trajectories for cations and anions due to the dipolar potential at the pore constriction. The pore seems to be optimised for high throughput and low selectivity.

The pore of the maltodextrin specific maltoporin (LamB) re-

veals an extended hydrophobic patch formed by six aromatic residues at the channel lining. As shown by X-ray crystallography maltodextrins bind to this *greasy slide* at the height of the channel constriction. The Conjugate Gradient Method has been employed to simulate the *register shift* of a maltohexaose sugar [2]. The results show that no large energy barriers have to be overcome, despite the presence of a multitude of protein-sugar hydrogen bonds.

Numerical approximation of solutions to nonlinear inverse problems. **Donald French** (University of Cincinnati, USA) IC/MT1750/122

Identification of detailed features of neuronal systems is an important challenge in the biosciences today. An interdisciplinary research team has been working to determine the distributions of ion channels in frog olfactory cilia. The cilia are tiny tube-like structures (0.2 microns in diameter) that extend from the olfactory receptor neurons. The first step in the transduction of an odor into an electrical signal occurs in the membranes of the cilia and is controlled primarily by the ion channels. A mathematical model involving integral and partial differential equations is derived to model experiments aimed at identifying features of the distribution of these ion channels. Numerical and analytical approximations to the model solutions are derived and used with experimental data to obtain estimates of the spatial distribution of the ion channels along the length of a cilium. The results from this mathematical and experimental study suggest that these channels have a non-uniform distribution.

Forward solvers for ion channels. **Marie Therese Wolfram** (Universität Münster, Germany) IC/MT2240/122

The main focus of our work is the mathematical description and numerical simulation of ion channels. A reasonable model are the so-called Poisson–Nernst–Planck (PNP) equations. We introduce a special linearization of the transient PNP equations, which leads to a mixed formulation. We briefly discuss the numerical aspects of such formulations, especially the use of low order Raviart–Thomas elements. Finally we illustrate our techniques with a 2D simulation of calcium selective ion channel.

A Poisson–Nernst–Planck model for biological ion channels: an asymptotic analysis in a 3-D narrow funnel. **Amit Singer** (Yale University, USA) IC/MT5038/122

We wish to predict ionic currents that flow through narrow protein channels of biological membranes in response to applied potential and concentration differences across the channel, when some features of channel structure are known. We propose to apply singular perturbation analysis to the coupled Poisson-Nernst-Planck equations, which are the basic continuum model of ionic permeation and semiconductor physics. In semiconductor physics the problem is a singular perturbation, because the ratio of the Debye length to the width of the channel is a very small parameter that multiplies the Laplacian term in the Poisson equation. In contrast to semiconductors, the atomic scale geometry of narrow ion channels sometimes makes this ratio a large parameter, which, surprisingly, renders the problem a singular perturbation in a different sense. We construct boundary layers and match them asymptotically across the different regions of the channel to derive good approximations for Fick's and Ohm's laws.

This is a joint work with John Norbury.

IC/MP405/122: Mathematics and mechanics in structural and functional biology: material modelling.

Organiser: Rolf Krause (Universität Bonn, Germany)
Co-organiser: Christian Hellmich (TU Wien, Austria)

Bones and soft tissues accommodate mechanical loading by distributing the biological material via interior and exterior growth in a somehow optimized manner.

The understanding and simulation of these processes is of great importance in many application areas as are surgery planing or the design of implants and prostheses. These biomechanical problems demand advanced interdisciplinary development upon a solid foundation of mathematics, mechanics, computing, engineering, and physical, chemical, and biological sciences. The aim of our minisymposia is to present and discuss in an interdisciplinary framework mechanical, mathematical, and computational tools in the area of structural and functional biology. One focus will be on the modeling of bones, including such phenomena as fracture healing. In the latter case different highly complex processes interact at different scales, from the molecular level over that where biological cells are observed, up to the macroscopic level apparent to the naked eye. These interactions are highly nonlinear, and their mathematical representation requires coupled multiscale and multiphysics models. The construction and analysis of efficient coupled models describing the mechanical properties of bone (and biological materials in general) as a result of ever changing biochemical cocktails provided through the well-tuned teamwork of biological cells (fibroblasts, osteoblasts, osteocytes, osteoclasts etc.) will be at the center of the talks and discussions in the proposed minisymposia.

Collagen fiber remodeling in arterial walls. **Ellen Kuhl** (TU Kaiserlautern, Germany) IC/MT2388/122

Functional adapation of biological tissues has advanced to a research topic of growing interest in the field of mechanobiology. The adaptation in response to mechanical loading can manifest itself in two fundamentally different forms: growth and remodeling. This contribution focusses on the latter with particular application to collagen fiber reorientation. A micromechanically motivated remodeling theory will be derived and applied to the adaptation of arterial microstructure which is known to remodel progressively to preserve circumferential wall stress and wall shear stress at a normal physiological level. Numerical examples will focus in partiular on the ongoing discussion whether stress or strain is the relevant quantity that drives the remodeling process.

Role of hydroxyapatite–collagen interactions on mechanics of collagen in human hard tissues. **Kalpana Katti** (North Dakota State University, USA), Dinesh Katti (North Dakota State University, USA), Rahul Bhowmik (North Dakota State University, USA) IC/MT3409/122

We have used structures of collagen-teliopeptide and hydroxyapatite to conduct molecular dynamics study to evaluate specific nature of hydroxyapatite-collagen interactions in human bones. The specific crystallographic planes of interaction of collagen with hydroxyapatite are identified. Further, we have also conducted a steered molecular dynamics study to evaluate the specific role of the bonded and non bonded interactions at the hydroxyapatite-collagen interface on the mechanics of the collagen. This study describes the role of molecular interactions during deformation in collagen while loading of bone.

Mechanics of mineral–protein interactions: a steered molecular-dynamics study. **Dinesh Katti** (North Dakota State University, USA) IC/MT3253/122

Hybrid interfaces are common in many structural biocomposites and nano-biocomposites. These mineral-organic hybrid interfaces and organic phase in biocomposites show unique mechanical behavior which many a times result in extraordinary properties exhibited by the bionanocomposite. In our current work, we focus on the aragonite-organic interface in a biological nanocomposite nacre, the shiny inner layer of seashells. Nacre which is a laminated biocomposite consisting of 95 to 98

Our previous work has shown the presence of platelet interlocks in nacre as key to the fracture toughness and strength in nacre (Katti etal. 2005). Our earlier work has also shown that the elastic modulus of organic phase which is predominantly proteins is exceptionally high (Katti etal. 1999, 2001). The organic phase has unique properties, very high elastic modulus and ability to deform considerably before failure. Recently we have shown that the mechanical response of proteins in the proximity of aragonite is significantly different from that of bulk proteins and shows some unique and distinct differences (Katti etal. 2005, 2006). The force required to unfold the protein in the proximity of aragonite is several times greater than the case in absence of the protein. In this work we describe our steered molecular dynamics simulations for studying aragonite-protein interactions and elucidate the mechanisms responsible for the extraordinary enhancement of mechanical response during protein unfolding in the proximity of aragonite.

Macro–micro characterization and modelling of human compact bone. **Marie-Christine Ho Ba Tho** (Université de Technologie Compiègne, France) IC/MT3586/122

The objectives of the present study were 1) to investigate the influence of multiscale structural characteristics of the bone tissue on its mechanical behavior and 2) to perform a macro-micro numerical modelling based on the experimental data. Ultrasound technique was used to assess the anisotropic behavior of cortical bone at the macrostructural level. Morphological measurements and mechanical testing were performed at that microstructural level. Morphological measurements were derived from ESEM images and mechanical testing consists of nanoindentation. In order to develop the mathematical model, variational approaches methods was used. From the knowledge of the mechanical characteristics of each constituent of the cortical bone at the microstructural level, variational approach to bound the elastic properties at the macroscopic level was used. The different steps of the mathematical modelling are 1) to describe the morphological patterns at the microstructural level, 2) to predict the effective elastic properties at the macroscopic level by the variational approach. The variation at the microstructural is related to the different degrees of maturation, mineralization of the osteons. The variation at the macrostructural level is related to microporosities of the cortical bone. Our mathematical model was validated by comparison between simulated results with that of the experimental data. Simulations allowed to quantify the effect of microporosities on the anisotropic behavior of bone, and effet of different morphological patterns on mechanical properties of bone. The mathematical model allowed the influence of the different patterns and their effect on the macroscopic anisotropic behaviour to be tested. One should note that in the first assumption of the isotropic behaviour of the mechanical properties at the microstructural level, one can predict the anisotropic elastic properties related to structural properties. Moreover, different possible structural and material configurations could be obtained for a same global macroscopic values. Other local distributions of patterns could be investigated reflecting bone pathology or else, then our model could be used to predict then global stresses, strain for such configuration. Conversely we emphasize the fact that, for a given global loading, the local strain or stress can be computed. For this point of view, one could estimate the local stresses inside the osteons. Moreover, investigations of the influence of the diameter of the Haversian canal and the size of the osteon lamellae could be performed. Finally, with the mathematical model, one can test the part of the structural and material anisotropy at the microstructural level on the macroscopic values. These simulations will provide a better understanding of the relationships between structural and material properties at different scale.

IC/MP405/122: Mathematics and mechanics in structural and functional biology: material modelling. #2

Universal micro-structural patterns in bone: continuum micro-mechanics-based prediction of anisotropic material behavior. **Christian Hellmich** (TU Wien, Austria), Andreas Fritsch (TU Wien, Austria) IC/MT3256/122

Bone materials are characterized by an astonishing variability and diversity. Still, because of ?architectural constraints?, their fundamental hierarchical organization or basic building plans remain largely unchanged during biological evolution. These building plans govern the mechanical interaction of the elementary components of bone (hydroxyapatite, collagen, water; with directly measurable tissue-independent elastic properties), which are here quantified through a multiscale homogenization scheme delivering effective elastic properties of bone materials: At a scale of 10nm, long cylindrical collagen molecules, attached to each other at their ends by 1.5nm long crosslinks and hosting intermolecular water inbetween, form a contiguous matrix called wet collagen. At a scale of several hundred nanometers, wet collagen and mineral crystal agglomerations interpenetrate each other, forming the mineralized fibril. At a scale of 5 microns, the solid bone matrix is represented as collagen fibril inclusions embedded in a foam of largely disordered (extrafibrillar) mineral crystals. Remarkably, needle and sphere type representations of disordered minerals deliver quasi-identical mechanical behavior of such extrafibrillar porous polycrystals. At a scale above the ultrastructure lacunae are embedded in extracellular bone matrix, forming the extravascular bone material. Model estimates predicted from tissue-specific composition data agree remarkably well with corresponding stiffness experiments across cortical and trabecular materials, which opens new possibilities in the

exploitation of computer tomographic data for nano-to-macro mechanics of bone organs, especially in combination with currently investigated extensions towards damage and failure.

Influence of tissue anisotropy versus inhomogeneity on the structural behaviour of an elderly human mandible. **Cornelia Kober** (FH Osnabrück, Germany), Christian Hellmich (TU Wien, Austria), Bodo Erdmann (Zuse-Institut Berlin, Germany) IC/MT2831/122

Within the biomechanics of bony organs, individual tissue anisotropy and inhomogeneity are intensively discussed subjects. This paper is dedicated to the impact of a fully anisotropic and inhomogoneous material description on the structural behaviour of an elderly partially edentulous human mandible.

Radial, axial, and circumferential trajectories of orthotropic elasticity were reconstructed from kind of inner skeleton derived from the organ's geometry and from coherent structures recognisable from the spatial distribution of the grey values coming from computer tomography (CT). Based on recent micromechanical research driven forward by the second author CT numbers were transferred into inhomogeneous stiffness tensor components reflecting individual tissue properties. These coefficients were considered as local orthoptropic elastic coefficients in reference to coordinate systems formed by the anisotropic trajectories of elasticity. For the sake of a complete anisotropic material description over the whole organ, the tensor components were transformed into a global base frame which allows assembling an overall patient-specific stiffness matrix.

Various sensitivity analysis revealed that the more the anisotropy is considered the more the mandible is spared from loading which indicates kind of mechanical optimality of the mandible with respect to tissue anisotropy. In the opposite, the consideration of individual inhomogeneous tissue properties resulted in intensification of load concentrations due to pathological alterations of the organ which gives rise to the suggestion of self-energising processes of bone resorption.

For the sake of reliability and efficiency, the numerical calculations were performed by means of the adaptive finite element code KASKADE, see www.zib.de/Numerik/numsoft/kaskade. The comparison of both the original (about 350.000 tetrahedra) and the refined mesh (about 800.000 tetrahedra) proved the simulation results as reliable.

Work done in collaboration with Stefan Stuebinger, Robert Sader and Hans-Florian Zeilhofer.

Universal morphological patterns in wood: micro-mechanics-based estimates for anisotropic stiffness and strength from composition and microstructure. **Karin Hofstetter** (TU Wien, Austria), Christian Hellmich (TU Wien, Austria), Josef Eberhardsteiner (TU Wien, Austria) IC/MT3299/122

Wood stiffness and strength are highly anisotropic. The material resistance in stem direction is about an order of magnitude higher than that orthogonal to the stem. Obviously, this anisotropy stems from the intrinsic structural hierarchy of the material. Wood is composed of wood cells, which are hollow tubes oriented in the stem direction. The cell wall is built up by stiff cellulose fibrils with crystalline cores and amorphous surfaces, which are embedded in a soft polymer matrix composed of hemicellulose, lignin, extractives, and water. The orientation of cellulose fibrils and tubular holes and the spatial gradation of porosity leads to anisotropy and inhomogeneity of the macroscopic material behavior.

The relation between (macroscopic) elastic material properties of wood and physical quantities at lower scales was recently expressed in the framework of continuum micromechanics. We here apply this model for estimation of the elastic properties of the wood cell wall, which are then related to macroscopic stiffness properties of wood by means of a unit cell approach. The latter allows for consideration of the plate-like bending and shear deformations of the wood cell walls, which are dominant at loading in the transverse direction. Model estimates for the elastic moduli and shear moduli of wood agree very well with corresponding experimental results.

Macroscopic material strength is governed by strain peaks in the material microstructure, which can be suitably characterized by quadratic strain averages over material phases, being effective for material phase failure. Macroscopic stress states estimated from local shear failure of lignin agree very well with corresponding strength experiments.

Analytical solution of crack problems in nacre. **Ko Okumura** (Ochanomizu University, Japan) IC/MT3301/122

Nacre is a remarkable nanoscale layered structure, which makes the beauty of pearl. This structure also contributes significantly to the unusual strength of this material. We show that the stress and strain distribution around a line crack in nacre, or similar layered structure, can be analytically obtained, in a certain mathematical limit relevant to nacre. The solutions reveal that the weakening of the stress concentration around the tip crack, which is one of the reasons of the unusual strength. We may also mention some scaling relations for fracture mechanical properties of natural cellular solids.

Analysis of nasal airflow phenomena using CFD simulations. **Stefan Zachow** (Zuse-Institut Berlin, Germany) IC/MT3560/122

Though treatment methods in ear, nose and throat surgery have constantly improved over time, the prediction of a successful individual therapy under consideration of regular nasal airflow remains a challenging task. Airflow simulations based on computational fluid dynamics are presented for a highly detailed anatomy of nasal airways, being reconstructed from tomographic data, including frontal and paranasal sinuses, naso-pharynx, and trachea. The simulation of complex airflow

characteristics with regard to individual anatomy enables us to study the physiology and pathophysiology of nasal breathing, thus being able to support treatment planning in functional rhinosurgery.

Efficient solution of non-smooth systems in biomechanics. **Rolf Krause** (Universität Bonn, Germany) IC/MT3145/122

Due to the inherent complexity of biomechanical systems, the solution of biomechanical problems in continuum mechanics is a challenging task. Understanding mechanical processes within, e.g. human joints or the spine requires carefull modelling and simulation, particularly in the case of multiscale models. In addition to the smooth nonlinearities, which might be induced by the material modelling, often constraints occur, e.g. for contact within joints. In this talk, we consider the influence of constraints and strong nonlinearities on the construction of discretizations and solutions methods in space and time in a biomechanical context. Different approaches are discussed and numerical examples and results are presented.

Cortical bone anisotropy due to mesoscopic porosity: investigations via asymptotic homogenization. **William Parnell** (University of Manchester, UK), Quentin Grimal (Université Pierre et Marie Curie, France), Pascal Laugier (Université Pierre et Marie Curie, France) IC/MT4394/122

A new model of cortical bone elasticity is developed and used to assess the influence of porosity on the macroscopic anisotropy of bone. In particular we use the method of asymptotic homogenization to determine the effective elastic properties of bone by modelling the propagation of low frequency elastic waves through the material. We use a novel solution of the cell problem developed by Parnell and Abrahams [1], [2] which is ideally suited to such a study due to its ability to model complex microstructure. Results, which are able to be computed efficiently (in seconds) are compared with existing homogenization and micromechanics schemes and finite element models from Grimal et. al. on real microstructures [3]. Parametric studies are performed in order to assess the influence of porosity and the assumptions regarding the constitutive behaviour of the material inside Haversian canals.

Apparent elastic properties of trabelcular bone. **Philippe Zysset** (TU Wien, Austria) IC/MT4988/122

Osteoporosis is a major health care issue in aging societies which is characterized by a reduction in bone mass and degradation of trabecular architecture leading to bone fractures. Using high resolution imaging technologies, the mechanical properties of trabecular bone can be simulated with classical or voxel-based finite element methods. As the computing resources required to simulate the mechanical behavior of whole bones or bone-implant systems with detailed trabecular architecture are prohibitive, the purpose of this study is to identify the most appropriate boundary conditions to calculate apparent properties of trabecular bone. Since the trabecular architecture exhibits nearly orthotropic symmetry, an artificial representative volume element is designed by mirroring the microstructure along the 3 orthogonal planes of symmetry. The effective elasticity tensors of artificial RVEs (10.4mm cubes) were computed with periodic boundary conditions (PBC) using a voxel based finite element method. Finally, kinematically uniform (KU), statically uniform (SU) and a novel set of mixed boundary conditions (BC) were applied to compute the apparent properties of the initial volume elements (5.2mm cubes). The KUBC leaded to an upper bound of the apparent elastic properties and overestimated significantly the effective properties of the mirrored volume calculated with PBC. The discrepancies increased with porosity and reached 400As a major result, the apparent elasticity tensors calculated with the novel set of mixed BC were nearly identical to the effective properties of the mirrored volume calculated with periodic BC. This novel set of mixed boundary conditions represents therefore an improved alternative to previous methods to compute realistic apparent elastic properties of trabecular bone.

IC/MP211/122: Stochastic biochemical systems.

Organiser: Peter Thomas (Case Western Reserve University, USA)
Co-organiser: Hong Qian (University of Washington, USA)

The chemical reactions by which living cells sense, control and respond to internal and external conditions typically involve small numbers of individual reactants. The stochastic nature of chemical reactions means that on the cellular or subcellular scale traditional methods of continuum, concentration based, chemical dynamics overlook essential phenomena. Reaction networks must overcome fluctuations as they attempt to maintain homeostasis or identify external signals, but they may also exploit noise to enhance stability or create movement. Topics to be discussed include fluctuations in cell motility, cellular communications and the statistical thermodynamics of open systems.

Mesoscopic and macroscopic open-system chemical dynamics. **Hong Qian** (University of Washington, USA) IC/MT3958/122

Chemical master equation (i.e., a birth-death process with continuous time), has become the mathematical foundation of chemical reaction kinetics in both small and large systems. In this talk, I shall discuss the unifying theory that encompasses both stochastic models and deterministic nonlinear chemical scillations. The essential difference between open and closed systems in terms of the "chemical detailed balance" will be discussed. The dynamic consequences of open-systems and their specific biological functions will be presented. For more information, see
http://dx.doi.org/10.1021/jp061858z,
http://dx.doi.org/10.1146/annurev.physchem.58.032806.104550.

Stochastic aspects of actin filament dynamics. **Hans Othmer** (University of Minnesota, USA) IC/MT4694/122

Actin polymerization and network formation are key processes in cell motility. Numerous actin binding proteins controlling the dynamic properties of actin networks have been studied and models such as the dendritic nucleation scheme have been proposed for the functional integration of at least a minimal set of such regulatory proteins. In this talk we will describe recent work on the evolution of the distribution of filament lengths and nucleotide profiles of actin filaments. The distributional dynamics of actin filaments are investigated in the framework of both deterministic and stochastic chemical kinetics. For the latter we develop a master equation for the biochemical processes involved at the individual filament level and simulate the dynamics by generating numerical realizations using a Monte Carlo scheme. A new computational algorithm that is far more efficient than standard methods will also be described.

Information-theoretic analysis of eukaryotic gradient sensing. **Peter Thomas** (Case Western Reserve University, USA) IC/MT4400/122

Chemical reaction networks by which individual cells gather and process information about their chemical environments have been dubbed "signal transduction" networks. Despite this suggestive terminology, there have been few attempts to analyze chemical signaling systems with the quantitative tools of information theory. Gradient sensing in the social amoeba *Dictyostelium discoideum* is a well characterized signal transduction system in which a cell estimates the direction of a source of diffusing chemoattractant molecules based on the spatiotemporal sequence of ligand-receptor binding events at the cell membrane. Using explicit Monte Carlo methods (MCell) we construct a simulation in which a collection of individual ligand particles undergoing Brownian diffusion in a three-dimensional volume interact with receptors on the surface of a static amoeboid cell. Adapting a method for estimation of spike train entropies described by Victor (originally due to Kozachenko and Leonenko), we estimate lower bounds on the mutual information between the transmitted signal (direction of ligand source) and the received signal (spatiotemporal pattern of receptor binding/unbinding events). Hence we provide a quantitative framework for addressing the question: how much could the cell know, and when could it know it? We show that the time course of the mutual information between the cell's surface receptors and the (unknown) gradient direction is consistent with experimentally measured cellular response times. We find that the acquisition of directional information depends strongly on the time constant at which the intracellular response is filtered; the equilibrium mutual information between the stimulus direction and the receptor states grows monotonically with larger time constants. However, for mean signal concentrations exceeding the equilibrium constant of the receptor, the mutual information peaks shortly after stimulus onset, suggesting that under some conditions cells should be expected to make directional decisions based on the transient receptor signal rather than on the long-time equilibrium signal.

Stability and robustness of synthetic band-pass response networks. **Attila Becskei** (Universität Zürich, Switzerland) IC/MT4998/122

Response to specified range of signalling intensity can be achieved by band-pass response networks. In order to increase the reliability and resistance to fluctuations, we designed the simplest possible network that at the same time neutralizes fluctuations. A single component gene circuit when combined with appropriate promoter logic displays a surprising robustness because it maintains band-pass response for all possible parameter values. At the same time the output fluctuations are small because correlated fluctuations appear in activating and repressing parts of the signalling pathway, which cancel out when combined.

IC/MP62/122: Dynamics of cell membranes.

Organiser: Axel Voigt (FZ caesar, Germany)
Co-organiser: Qiang Du (Pennsylvania State University, USA)

Biomembranes are a mixture of many different types of lipidic and protein components, and their relative amounts and composition differ between functionally distinct domains. In equilibrium membranes and in particular vesicles have been investigated intensively using a curvature-elastic model. However today curvature is no longer seen as a passive consequence of cellular activity but an active means to create membrane domains and to organize centres for membrane trafficing. Membrane curvature is thus a prime player in growth, division and movement of cells.

Recent advancements in applied mathematics allow the simulation of dynamic evolution of vesicles, with multiple components under the influence of flow. The underlying model includes the interaction of liquid with the elastic membrane, phase seperation and coarsening of composition on the membrane and the geometric evolution of the membrane according to curvature effects. The problem is a highly nonlinear free bounday value problem for which various numerical methods have been developed including phase-field, level-set and immersed boundary methods.

Surface-phase separation and flow in models of multicomponent vessicles. **John Lowengrub** (University of California, Irvine, USA) IC/MT3249/122

We introduce and investigate numerically a thermodynamically-consistent simple model of a vesicle in which the interfacial surface contains multiple constitutive components (e.g. amphiphilic molecules). The model describes the nonlinear coupling among the flow, vesicle morphology and the evolution of the surface phases. We consider a version of the Helfrich model for fluid- like vesicle membranes. To solve the highly nonlinear, coupled system a new numerical method is developed. This method combines the immersed interface method to solve the flow equations, and the Laplace–Young jump conditions, with the level-set method to represent and evolve the interface and a non-stiff Eulerian algorithm to update the mass concentration on the drop interface. Results are presented for vesicles in an applied shear flow where an initially unstable mixture of the surface mass separates into distinct phases.

Instabilities of inhomogeneous lipidic membranes. **Martine Ben Amar** (École Normale Supérieure de Paris, France) IC/MT4082/122

Lipid bilayer membranes are formed of multiple lipids which may separate into coexisting liquid phases with distinct compositions and physical properties. In cell biology, microdomains called rafts are receiving increasing attention since they are believed to concentrate proteins that must interact with one another to carry out important cellular functions. Here, we investigate the relationship between the curvature elasticity and the line tension of domains and the resulting formation of particular patterns or membrane shapes. Starting from the standard Canham-Helfrich elastic model, we write the free energy of our membrane restricted to two domains in order to allow axi-symmetry. Conserved quantities like the surface area are imposed via Lagrange multipliers while the semi-permeability of the membrane induces a global osmotic

pressure. When this pressure is strong enough, the vesicle is stretched and each phase takes approximatively the shape of a spherical cap. In this limit, the bending elasticity is negligible except in places of high curvature, that is at the border between the two domains. We derive an asymptotic model and show that a two-domain vesicle exists for a set of parameters such that the order parameter defined by the line tension divided by the pressure times the vesicle size remains below a critical value. Above this value, the two domains separate and two homogeneous vesicles appear. Our model explains the budding of a raft phase by an osmotic shock or by insertion of proteins like PLA2. Another aspect of the membrane physics, more important from a biological point of view, concerns the fluidity of the membrane.The viscous properties of membranes have been less explored and most of the experimental or theoretical works concern the diffusion of particles. Here, we suggest to use the difference between the two viscosities of the domains to exhibit contour instabilities analogous to the Saffman-Taylor instability in viscous fingering. The hydrodynamics of the membrane has been established by Saffman in the case of diffusion. We adapt the Saffman model to an hydrodynamic flow induced by suction. We show that suction may induce a border instability in an inhomogeneous membrane, the number of contour oscillations being related to the contrast of viscosities. Our theoretical treatment is illustrated by the suction of the raft phase in an inhomogeneous vesicle by human blood HDL (High-density lipoproteins).

Dynamics and rheology of vesicle suspension. **Chaouqi Misbah** (Université Grenoble I, France) IC/MT4913/122

Vesicles under shear flow exhibit various dynamics: tank-treading (tt), tumbling (tb) and vacillating-breathing (vb). We present first an analytical theory about these dynamics. We show a direct bifurcation from tt to tb if $C_a \equiv \tau\dot{\gamma}$ is small enough (τ= vesicle relaxation time towards equilibrium shape, $\dot{\gamma}$=shear rate). At larger C_a the tb is preceded by the vb mode. For $C_a \gg 1$ the vb mode coexists with tb. We analyse rheology and find that the effective viscosity exhibits a minimum at $tt-tb$ and $tt-vb$ bifurcation points. We present numerical results from boundary integral formulation and a phase field model. We also discuss other features, such as migration in Poiseuille flow, and the behaviour close to a substrate.

Equilibrium and dynamics of biomembranes. **Ricardo Nochetto** (University of Maryland, USA), Miguel Sebastian Pauletti (University of Maryland, USA), Andrea Bonito (Univ. Maryland at College Park, USA) IC/MT5035/122

When lipid molecules are immersed in aqueous environment they aggregate spontaneously into 2 mono-molecular layers or (bio-)membranes that form an encapsulating bag called *vesicle*. This happens because lipids consist of a hydrophilic head group and a hydrophobic tail, which isolate itself in the interior of the membrane.

As a first approach, we have studied a model based on geometry assuming that the equilibrium shapes are the minimizers of the Willmore energy under area and volume constraints. In this context, the biomembrane is the preponderant factor influencing the shape of the vesicle. A gradient flow is established to reach these equilibrium shapes. Then, the effect of the inside (bulk) fluid is taken into account leading to more physical dynamics. The boundary conditions couple Stokes equations to the constrained Willmore force. Some fourth-order fully-nonlinear problems that arise are solved using an adaptive finite-element method.

IC/MP62/122: Dynamics of cell membranes. #2

(For abstract, see session #1 above.)

Phase-field modeling and simulations of cell membranes. **Qiang Du** (Pennsylvania State University, USA) IC/MT155/122

In this talk, we report some of recent works with colleagues at Penn State on the phase field modeling and simulations of the vesicle membrane deformation under elastic bending energy and the interaction with background fluid flows and other external fields. We discuss the relations between the phase field model and the sharp interface limits. We also numerical simulations of membranes with various topology.

Modeling of multicomponent lipid vesicles. **Axel Voigt** (FZ caesar, Germany), Andreas Rätz (FZ caesar, Germany) IC/MT556/122

We derive a thermodynamical consistent model for the dynamics of lipid vesicles with multiple components. The model consists of a coupled system of a Cahn-Hilliard like equation for the concentration on the surface and a Willmore-flow like equation for the evolution of the surface under constraints on volume and surface area. We discuss different numerical approaches for this model (phase-field, level-set and parametric) and show numerical results demonstrating the strong interplay of composition and curvature.

A stochastic immersed-boundary method incorporating thermal fluctuations: toward modeling cellular micromechanics. **Paul Atzberger** (University of California, Santa Barbara, USA) IC/MT588/122

The mechanics of many cellular systems involve elastic structures which interact with a fluid, for example the outer cell membrane deforms during protrusions generated during motility and cell organelles such as the Golgi Apparatus and Mitochondria involve membranes which deform and bud vesicular and tubular structures during biological processes. Modeling, analyzing, and simulating the mechanics of such systems presents many mathematical challenges. The immersed boundary method is one modeling approach for such systems, and has been applied to many macroscopic biological problems, such as blood flow in the heart and lift generation in insect flight. At the length scales of cells and cell organelles, thermal fluctuations also become significant and must be taken into account. In this talk we discuss an extension of the immersed boundary method framework which incorporates thermal fluctuations through appropriate stochastic forcing terms in the fluid equations. This gives a system of stiff SPDE's for which standard numerical approaches perform poorly. We discuss a novel stochastic numerical method which exploits stochastic calculus to handle stiff features of the equations. We further show how this numerical method can be applied in practice to model the basic microscopic mechanics of polymers, polymer knots, membrane sheets, and vesicles. We also discuss work on modeling the dynamics of cellular membranes.

Dynamic instabilities in biological membranes. **Aurora Hernández-Machado** (Universitat de Barcelona, Spain) IC/MT941/122

We study pearling instabilities in biomimetic vesicles motivated by recent experiments. The pearling is induced by the anchoring of amphiphilic polymers. We use a phase-field model which reproduces both equilibrium and non-equilibrium shapes

IC/MP689/122: Computational medicine.

Organiser: Martin Weiser (Zuse-Institut Berlin, Germany)
Co-organiser: Peter Deuflhard (Zuse-Institut Berlin, Germany)

This minisymposium covers a broad range of scientific-computing applications in medicine, including cardiovascular flows, cardioelectric patterns, biomechanics and cancer treatment. The unifying theme is the use of PDE models for the biophysical and medical situation. The targets of the presented work range from fundamental understanding of physiological processes up to individual treatment design, and involve modelling as well as simulation and optimization.

A multiscale model of thermo-regulation in the cancer therapy regional hyperthermia. **Peter Deuflhard** (Zuse-Institut Berlin, Germany), Martin Weiser (Zuse-Institut Berlin, Germany) IC/MT2341/122

Regional hyperthermia with microwave radiation is a cancer therapy aiming at heating deeply seated tumors in order to make them more susceptible to an accompanying radio- or chemotherapy. In the standard case, diffusion and cooling by perfusion of arterial blood dominate the temperature distribution. The talk presents a multiscale perfusion model that introduces a hierarchical coupling between vessels of different size as well as a regional coupling between tissue areas (steal effect). This multiscale model is able to reproduce effects observed in clinical practice and offers new possibilities for optimizing individual treatment plans. Numerical results for clinical data are presented.

Towards efficient and reliable simulation of musculo-skeletal loading in the human knee. **Ralf Kornhuber** (Freie Universität Berlin, Germany), Oliver Sander (Freie Universität Berlin, Germany), Rolf Krause (Universität Bonn, Germany) IC/MT3287/122

A precise prediction of loads and forces within human joints would support surgical decisions and thus increase the overall success of hip and knee surgery procedures. However, preoperative in vivo measurements are hardly possible and credible numerical simulation is a demanding task. In this talk, we consider 3D finite element models of the human knee with patient-specific geometry and particularly concentrate on efficient and reliable solvers based on domain decomposition and monotone multigrid.

Contact in joints: on the stability of multi-level solution methods for biphasic materials. **Rolf Krause** (Universität Bonn, Germany) IC/MT3191/122

Biphasic materials are often employed for the modelling and the numerical simulation of articular cartilage within joints. In combination with frictional or frictionless contact, the numerical solution of the arising discrete non linear systems is a demanding task, in particular for realistic geometries. We consider the stability and efficiency of different multilevel approaches for the numerical solution of the resulting non-smooth systems. A multilevel method is derived which allows for the efficient solution of these non-linear systems, including nonlinearities as contact and friction. Numerical examples on problem specific geometries in three space dimensions are given.

Mechanism of IP_3 induced intracellular Ca^{2+} oscillations. **Martin Falcke** (Hahn-Meitner-Institut Berlin, Germany) IC/MT1442/122

Oscillations on cellular level can arise by several fundamentally different mechanisms. The whole cell or parts of it may represent an oscillatory medium with oscillatory local dynamics or global events may be initiated repetitively by non-periodic processes like repetitive wave initiation. The first mechanism implies regular interspike intervals (ISI) while the second one entails ISI distributions exhibiting a linear dependence of the standard deviation on the average ISI. We show that experimental results support the second mechanism.

That provides the frame for a theory of intracellular Ca^{2+} dynamics as a hierarchy of stochastic events and with probabilities to be determined by a new theory of intracellular Ca^{2+} oscillations. We present first results of this theory.

IC/MP689/122: Computational medicine. #2

Co-organiser: Peter Deuflhard (Zuse-Institut Berlin, Germany)

(For abstract, see session #1 above.)

Cardiovascular flow modelling. **Alfio Quarteroni** (École Polytechnique Fédérale de Lausanne, Switzerland) IC/MT1422/122

In this talk I will present some recent advances on the modelling of the cardiovascular system, the simulation of physiopathological flow conditions, the control and optimisation of prosthetic operations.

Simulating the electrical activity in the atria with applications to radio-frequency ablation. **Aslak Tveito** (Simula Research Laboratory, Norway), Svein Linge (Simula Research Laboratory, Norway), Mary MacLachlan (Simula Research Laboratory, Norway), Glenn Lines (Simula Research Laboratory, Norway) IC/MT1676/122

Irregularities in the electrical activity of the atria reduce the efficiency of the heart muscle and reduce the patient's ability to continue normal physical activity. Such irregular wave-patterns can be cured by delivering radiofrequency energy to the heart muscle and thereby destroy arrhythmogenic foci. In order to do this, the physician has to understand the wave pattern. This is currently done by performing careful measurements of the electrical signals. Although such measurements provide important information about the wave pattern, it is reasonable to assume that further insight can be gained by combining the measurements with a simulator which may provide a much more detailed view of the wave pattern. It is the purpose of this talk to discuss how this process can be simulated by solving a system of partial differential equations modelling the electrical activity of the atria. In particular, we will discuss how to incorporate measured data into the simulator. Simplified examples will be provided combined with simulation results based on real 3D atrial data.

Adaptivity in space and time for reaction–diffusion systems in computational electro-cardiology. **Luca Pavarino** (Università degli Studi di Milano, Italy), Peter Deuflhard (Zuse-Institut Berlin, Germany), Piero Colli Franzone (Università degli Studi di Pavia, Italy), Jens Lang (TU Darmstadt, Germany), Bodo Erdmann (Zuse-Institut Berlin, Germany) IC/MT1726/122

Advanced multiscale models in computational electrocardiology offer a detailed representation of the heart bioelectrical activity, ranging from the microscopic description of ion channels of the cellular membrane to the macroscopic properties of anisotropic front propagation in the whole heart. The models considered here are the Monodomain or Bidomain tissue representation that includes orthotropic anisotropy and homogeneous or heterogeneous intrinsic membrane properties, described by either the simpler FitzHugh-Nagumo model or the more complex Luo-Rudy phase I model. Numerical simulations are based on the multilevel 3D code Kardos, which employs adaptive linearly implicit methods in time and adaptive finite elements in space. The simulation results show that the method accurately resolves the evolution of the intra- and extracellular potentials, gating variables and ion concentrations during the excitation, plateau and recovery phases of the heartbeat.

Numerical simulations of arterial plaque ruptures. **Anna Pandolfi** (Politecnico di Milano, Italy), Anna Ferrara (Politecnico di Milano, Italy) IC/MT2622/122

Atherosclerosis is a vascular disease characterized by accumulation of lipids, collagen, muscle fibers, macrophages, calcium and necrotic tissue in the vascular wall. Atherosclerotic plaque rupture is a common cause of acute myocardial infarction and unstable angina. *Vulnerable* plaques –non calcified eccentric plaques with a thinning fibrous cap, a large lipid pool, and macrophage infiltration– are prone to rupture at locations where the stress induced from biomechanical and haemodynamic forces exceeds the intrinsic strength of the material.

We present three-dimensional finite element models of damaged arteries, used to investigate the influence of the geometry and tissue properties on the plaque rupture. The plaque rupture can by caused by an external mechanical action (balloon angioplasty) or by a spontaneous fatigue process (pulse pressure).

We adopted two geometrical models, one based on a simplified geometry, the second reconstructed from a contiguous set of *in vitro* magnetic resonance images of a damaged artery. The simpler model is used to investigate the influence of the geometry and composition of the plaque on the results of balloon angioplasty. The more sophisticated model is used to evaluate quantitatively the stress distribution induced by the mechanical action in the arterial tissue.

The artery wall, composed by three layers (intima, media and adventitia), is discretized with tetrahedral finite elements. The material is modelled with the hyperelastic anisotropic model proposed by Holzapfel et al. [1]. The material properties are calibrated by fitting experimental data available in the literature. The physical interface between plaque and artery is modelled with cohesive elements, as well as the fracture surfaces induced by the mechanical action. The fracture surfaces, lying along solid elements boundaries, are explicitly introduced in the model only when the tensile strength of the material is reached.

IC/MP128/012: Modeling and parameter estimation for cardio-respiratory and metabolic control systems.

Organiser: Jerry Batzel (Universität Graz, Austria)
Co-organiser: Mostafa Bachar (Universität Graz, Austria)

This minisymposium focuses on modeling the complex control interactions of the human cardio-respiratory (CVRS) and metabolic control systems. Medical conditions related to these control systems are at the center of concern for health policy planning especially as the current population ages. These medical conditions include orthostatic intolerance in the elderly, increasing incidence of diabetes, and autonomic dysfunction due to diabetic neuropathy. Modeling efforts seek to develop better quantitative understanding of the complex interaction of various control loops leading to potential clinical applications. However model validation and in particular application of such models to the clinical setting face key hurdles due to the significant number of parameters involved in models that reflect physiological mechanisms together with the clinical constraint of generally non-invasive patient testing which generates a restrictive set of data from which parameters can be estimated. Furthermore, the inter-individual variation in a physiological system's inventory of control responses adds further complication to model application for diagnosis and treatment design. For this reason special emphasis is placed on discussing issues involved in model validation strategies, data acquisition, and strategies for applying reduce models for clinical use. These modeling problems represent an important challenge to current research. This challenge will be met through continuous advancement in mathematical and numerical methodologies together with new measurement techniques for minimally-invasive or non-invasive measurement of a wider range of physiological quantities as well as by the active interdisciplinary interaction of mathematicians, physiologists, and medical clinicians.

Stochastic modeling of the dynamics in heart-rate variability. **Susanne Ditlevsen** (Københavns Universitet, Denmark), Niels-Henrik Holstein-Rathlou (Københavns Universitet, Denmark), Jørgen Kanters (Københavns Universitet, Denmark) IC/MT2342/0

The isolated sinus node is a periodic oscillator, but the interaction between the sympathetic and the parasympathetic nervous system causes the output from the sinus node to fluctuate in an apparently random manner. The physiological mechanisms underlying the dynamic behavior of the heart rate remains unsettled.

Here we propose a stochastic model to quantify the variability. The goal is to characterize malignant arrythmias and other heart failures contrasted to healthy subjects through convenient stochastic processes modeling the dynamics of the potential governing the heart beat.

Subject specific parameters are estimated using a recently developed estimation procedure developed by us to make inference about the underlying process of the membrane potential from data of the interspike intervals in neurons.

Sensitivity analysis and their application in biomedical modeling. **Franz Kappel** (Universität Graz, Austria) IC/MT2928/0

In this talk we will demonstrate the important of classical sensitivity analysis and general sensitivity analysis in the development of global models for biomedical application. Two biomedical applications will be given, one in Glucose-Insulin control in Type 1 diabetes and a second one related to a large cardiovascular and respiratory system model. We will seek to demonstrate that the combined application of both forms of sensitivity analysis are important for the problem of identification of parameters for such large systems.

Evaluation of pancreas transplant function in patients with type-1 diabetes mellitus. **Mostafa Bachar** (Universität Graz, Austria) IC/MT2914/0

In this talk we describe a model of the Insulin-glucose system in regards to pancreas transplant function in patients with Type 1 Diabetes Mellitus. We discuss approaches to data acquisition and news experiments made over an extended time frame in order to identify the parameters and to estimate beta-cell mass using Kalaman filtering methods, classical sensitivity analysis and general sensitivity analysis.

Analyzing short-term cardiovascular-respiratory control mechanisms. **Jerry Batzel** (Universität Graz, Austria) IC/MT2923/0

In this talk we discuss the problem of studying the interaction of the cardiopulmonary and arterial baroreflex interactions in modulating the responses to various forms of short-term hypovolemia in the human cardiovascular-respiratory system. The end product of such research will be to have a model that can quantitatively describe the interaction of the main baroreflex control loops that are primarily involved in short-term control. We will discuss various potential forms of control interactions and a variety of experimental data that can be used to pinpoint the nature of these interactions. Sensitivity analysis and other strategies of model analysis will be applied to study the model and experimental design and issues involved in the person-to-person variation in the combination of these control interactions. A validated model that could reflect the wide spectrum of clinical data on short-term control impairment could aid in the understanding and treatment of acute hypovolemic stress.

IC/MP128/012: Modeling and parameter estimation for cardio-respiratory and metabolic control systems. #2

Estimating infant respiratory parameters. **Martin Fink** (University of Oxford, UK) IC/MT2948/0

In this talk we will discuss problems associated with estimating parameters important for evaluating infant respiratory control function. We will discuss a model of respiratory control and apply sensitivity analysis and other methods for evaluating which parameters are estimatable from typical data available in the clinical setting.

Quantitative sensitivity analysis for model assessment: mathematical models for blood pressure and flow regulation. **Hien Tran** (North Carolina State University, USA) IC/MT3126/0

Sensitivity analysis addresses the question of how particular model outputs vary as the model parameters are perturbed about some nominal values. This type of model analysis is important since it will make it possible to identify which parts of the complex model are being utilized and how. This information is very useful to mathematical modelers as it allows them to simplify or reduce model complexity. Finally, sensitivity analysis is also beneficial to experimentalists as part of their experimental design. In particular, data for which the model is sensitive would need further characterization, as opposed to data for which the model is relatively insensitive. In this talk, we will illustrate this type of sensitivity based model analysis on mathematical models for the blood pressure and flow regulation during postural change from sitting to standing. In our previous studies, a cardiovascular model was developed describing blood pressure and low, compliance, and resistance in the heart and systemic circulation. This closed-loop model includes 11 compartments and two submodels: (a) a cardiovascular model that can predict blood pressure and ow velocity during sitting and (b) a control model that can predict autonomic and cerebral regulatory mechanisms during the postural change from sitting to standing. For the sensitivity analysis studies, we focus on the steady-state problem (during sitting). Even with steady-state consideration, the mathematical model involves 48 parameters that need to be estimated from experimental data. However, sensitivity analysis showed that out of 48 parameters, only 10 parameters are sensitive to the physiological data. Furthermore, sensitivity analysis makes it possible to reduce the complexity of the mathematical model. Finally, we present validation results of the reduced order model against data that consist of arterial blood pressure measurements from the finger and cerebral arterial blood flow velocity measurements.

Heart-rate regulation during postural change from sitting to standing. **Mette Olufsen** (North Carolina State University, USA) IC/MT3176/0

During posture change from sitting to standing, blood pools in the lower extremities of the body, leading to a decrease in blood pressure in the upper body and the brain and an increase in blood pressure in the legs. In subjects with orthostatic intolerance, postural change may cause dizziness, lightheadedness, or even fainting. The exact function of the cardiovascular and respiratory regulatory mechanisms in response to such orthostatic stress is not well understood, and our work aims to develop mathematical models that can help describe these regulatory mechanisms in more detail. One of these regulatory factors is heart rate, which is increased during postural change from sitting to standing. Changes in heart rate are mediated partly due to parasympathetic withdrawal, partly from a delayed sympathetic activation, and partly from musclesympathetic stimulation. In this work we present a model that predicts heart rate regulation during sit-to stand. Key elements of the heart rate model include a time-delay between sympathetic and parasympathetic nervous responses and an impulse function that predicts the vestibular response accounting for subjectŠs physical preparation for standing. Based on these responses we predict chemical changes of noradrenaline and acetylcholine and use an integrate and fire model to predict heart rate. This model has been validated against data from groups of healthy young, healthy elderly, and hypertensive elderly subjects.

Cheyne–Stokes respiration with cardiovascular pathologies. **William Langford** (University of Guelph, Canada) IC/MT4587/0

This work presents a compartmental model of the human cardio-respiratory system, simulating the factors that determine the concentrations of carbon dioxide in the compartments of the cardiovascular system and the lungs. The parameter set on which a Hopf bifurcation gives rise to Cheyne-Stokes respiration (CSR) has been determined. The model predicts that the onset of CSR oscillations may result from an increase in any of: ventilation-perfusion ratio, feedback control gain, transport delay, left heart volume, lung congestion or cardiovascular efficiency. The model is employed to investigate the relationship between CSR and serious cardiovascular pathologies, such as congestive heart failure and encephalitis, as well as the effects of acclimatization to higher altitudes. In all cases, the model gives good agreement with medical observations.

IC/MP233/012: Tissue deformation and cell motility: a new frontier in cancer modeling.

Organiser: Didier Bresch (Université de Savoie, France)
Co-organiser: Thierry Colin (INRIA Futur Bordeaux, IMB, France)
Co-organiser: Emmanuel Grenier (École Normale Supérieure de Lyon, France)

Modeling tumor growth is one of the most challenging and complex issue of biomathematics. This session focuses on the design and validation of specific models of tissue deformation and cell motility. Such models combine mechanical aspects together with chemiotaxis and biochemical phenomena, and are of primary importance for the understanding of metastasis or local invasion.

Taxis equations and cell motility. **Radek Erban** (University of Oxford, UK) IC/MT4578/0

Motile cells sense their environment and can respond to it either by directed movement toward or away from a signal, which is called taxis, or by changing their speed of movement and/or frequency of turning, which is called kinesis, or by a combination of these. These behavioural responses of different cell types will be analyzed. The corresponding taxis (partial differential) equations will be derived and its consequences presented, e.g. we show how experimentally-measured statistics can be obtained from the taxis equations.

Modelling and simulations of fibrous biological tissues via discrete homogeneization methods. **Vuk Milišić** (Université Grenoble I, France) IC/MT4762/0

Thanks to their geometrical organization at the cell level, muscle fibers and soft biological tissues can be modelled from the mechanical point of view as multidimensional networks of elastic bars. The length of the bars is supposed to be small with respect to the size of the macroscopic medium. We introduce a detailed description of the overall structure accounting both for the tensions due to bars and for the moments between pairs of bars. Using quasi-periodicity hypotheses, we apply a discrete homogenization technique, see [Caillerie, D. and Mourad, A. and Raoult, A., J. Elasticity, 2006]. This allows to pass to the limit when the size of the bars goes to 0. In such a way we derive a continuous homogenized mechanical law in the large transformation setting which has the structure of a membrane law. The expression of the stress tensor in terms of the deformation gradient is implicit. It involves an intermediate problem at the elementary brick level. This problem whose unknown are ordinary vectors is solved by means of an iterative method. We describe the basic principles of this approach that was first introduced in the cardiac modeling context in [Mourad, A. Phd thesis]. In a second step, we consider stability issues w.r.t. to the type of elastic energy used for bars and the corresponding parameters' values. In a last step we present its implementation in a finite element framework. We illustrate our method with numerical results related to mechanical behaviour of cardiac muscle fibers in 3D.

Mechanical models of tumour growth. **Luigi Preziosi** (Politecnico di Torino, Italy) IC/MT4492/0

The talk will deal with the multiphase framework recently developed to describe tumor growth. In particular the second part of the talk will focus on the potential role that stress responsiveness may play in causing proliferative disorders which are at the basis of the development of avascular tumours. We in fact study how an incorrect sensing of its compression state by a cell population can represent a clonal advantage and can generate hyperplasia and tumour growth with well known characteristics such as compression of the tissue, structural changes in the extracellular matrix, change in the percentage of cell type (normal or abnormal), extracellular matrix and extracellular liquid. A spatially independent description of the phenomenon is given initially by a system of nonlinear ordinary di erential equations which is explicitly solved in some cases of biological interest showing a first phase in which some abnormal cells simply replace the normal ones, a second phase in which the hyper-proliferation of the abnormal cells causes a progressive compression within the tissue itself, and a third phase in which the tissue reaches a compressed state, which presses on the surrounding environment. The space-dependent evolution in a two-dimensional set-up is then described numerically.

A mathematical model for tumor growth. **Olivier Saut** (Université de Bordeaux 1, France), Didier Bresch (Université de Savoie, France), Thierry Colin (INRIA Futur Bordeaux, IMB, France), Emmanuel Grenier (École Normale Supérieure de Lyon, France), Benjamin Ribba (Université Claude Bernard Lyon I, France) IC/MT4473/0

We present a multi-scale model of avascular tumor growth. This model takes the cell-cycle into account and several environmental conditions which could affect tumor growth (namely hypoxia, overcrowding).

For this matter, we describe the evolution of the proliferative and quiescent phases through several PDEs. The environment appears as a source term and as boundary conditions in these equations. To model hypoxia, we also have to compute the evolution of the oxygen distribution through a diffusion equation.

Furthermore, through a level-set formulation, this model can render the mechanical effects of an elastic membrane surrounding the cancer cells. This membrane is also degraded by tumor cells.

The velocity of the movement created by the cellular division (and the corresponding increase of volume) is obtained as solution of a Stokes equations. The elastic force due to the membrane we have just mentioned appears as a source term in these equations (and is vanishing outside the smoothed interface).

We also present the numerical methods used to discretize this model in three dimensions. With these numerical schemes, we show various numerical experiments highlighting the accuracy of the model. Finally, we will describe several extensions (*e.g.* angiogenesis) and applications to therapeutical innovation.

IC/MP591/123: Modelling cancer growth and treatment.

Organiser: Thomas Hillen (University of Alberta, Canada)
Co-organiser: Herb Freedman (University of Alberta, Canada)

This minisymposium consists of four talks related to the modelling of the growth and treatment of cancer and its dynamical relations to healthy cells. Most of the modelling involves ordinary, partial and functional differential equations. Each speaker will address one or more aspects of growth modelling and/or treatment, including a survey of models involving competition between healthy and cancer cells.

The tumor control probability in radiation treatment. **Thomas Hillen** (University of Alberta, Canada) IC/MT5041/123

The Tumor Control Probability (TCP) is an index that measures the expected success of a given radiation treatment schedule. The literature provides various models for the TCP, where the best known are the binomial and the Poissonian models, which are based on the LQ-formalism (linear quadratic model).

Through the fast developments in clinical studies, more and more detailed information becomes available and we should look into more detailed models for the TCP that can include current new insights. In 2000, Zaider and Minerbo developed a TCP model that includes the exact time course of the treatment. Dawson and Hillen extended this model to include cell cycle dynamics, since it is known that quiescent cells are less radio sensitive than proliferating cells.

In my talk I will explain all these models and compare their predictions. I will use the TCP models to compare 10 different treatment schedules including hypo- and hyper-fractionation schedules. (Joint with A. Dawson, O. Yurtseven, G. de Vries).

Mathematical modelling of radio-therapy: treatment success and hazards. **Heiko Enderling** (Tufts University, USA) IC/MT1861/123

When local treatment of breast cancer moved away from mastectomy to the less radical lumpectomy, it was realized that radiotherapy was essential to reduce local recurrence rates. The need to irradiate the whole breast after breast conserving surgery for early breast cancer, however, is currently being questioned and new radiotherapy schedules and techniques are being tested in clinical trials. Furthermore, recent trials aim to simplify radiotherapy by delivering fewer, larger fractions without compromising effectiveness. It may be possible to predict the results of these trials using sophisticated mathematical models, which incorporate new molecular oncology data, to capture the tumour dynamics and treatment response. We have created a mathematical model that simulates successively, the development, growth and invasion of a solid tumour within the breast; recurrence after surgery and the effect of radiotherapy. We will examine a range of current and prospective irradiation protocols that give the best chance for treatment success and minimize patient inconvenience. Additionally, we discuss the potentially hazardous side effects of new irradiation protocols with higher individual doses delivered in fewer fractions, as well as low dose screening protocols that are aimed at detecting breast cancer early.

Hypertumors in malignant neoplasia can be caused by tumor phosphorus demand. **John Nagy** (Scottsdale Community College, USA) IC/MT2007/123

In cancer, tumoral and peritumoral environmental conditions are controlled mostly by the unusual metabolism of malignant cells. Cancer cells are very metabolically active, and so require large amounts of reduced carbon, supplied as glucose. In addition, tumor cells need certain chemical elements for structural molecules. For example, tumors typically demand much more phosphorus (P) than normal tissue does, primarily because tumor cells upregulate ribosome biogenesis, which requires P. Because the body attempts to maintain homeostasis only in support of normal tissue function, tumors deplete resources locally in the short term. In the long term the depletion can become systemic, ultimately leading to cachexia, the most common cause of death in cancer victims. Here I use mathematical models to show that this unusual demand for P can lead to a hypertumor, which is a region of highly aggressive cells that grows parasitically on the original tumor and can kill all or part of it. Previous work has suggested that hypertumors may develop when a tumor is invaded by an aggressive cell type that fails to secrete angiogenesis factors. In this talk I introduce an entirely different mechanism of hypertumor development. In this case, the aggressive strain depletes P in the tumor interstitium, causing a decline in tumor growth rate or, in some cases, necrosis. If the tumor is large, this increased P demand speeds the patient towards cachexia. So, a hypertumor's effect both locally and systemically depends on the physiological state of the host and the developmental stage in which the hypertumor arises.

Motility and growth of cells as seen through the eyes of the Fisher–Kolmogorov equation. **Peter Hinow** (Vanderbilt University, USA), Glenn Webb (Vanderbilt University, USA) IC/MT5042/123

Transforming growth factor (TGF) β is a signaling molecule involved in a variety of cellular processes including growth, differentiation, apoptosis and cell motility. While TGF-β slows proliferation of certain cell types it also increases their motility and may decrease cell-cell adhesion. Thus, it has properties of both a tumor suppressor and a tumor promoting factor. We have carried out experiments to quantify cell motility and growth in presence of TGF-β and use a version of the classical Fisher–Kolmogorov equation to interpret the experimental findings.

This is joint work with Shizhen Wang, Nicole Bryce (Department of Cancer Biology) and Glenn F. Webb (Department of Mathematics, Vanderbilt University).

IC/MP189/124: New research in bioinformatics.

Organiser: Conrad Burden (Australian National University)
Co-organiser: Susan Wilson (Australian National University)

Bioinformatics is a rapidly growing interdisciplinary field concerned with the use of computational methods to solve biological problems related to DNA and amino acid sequence information. This minisymposium presents recent research from a broadly representative range of subfields within bioinformatics, namely 1. Comparative genomics: the comparison of DNA and amino acid sequences to identify evolutionarily related segments; 2. Gene regulatory networks: understanding how genes interact to control protein production through complex networks; 3. Protein structure: determining the geometric structure of protein molecules and 4. Microarrays: developing accurate high throughput technology for measuring gene expression within cells.

Asymptotic behaviour and optimal word size for exact and approximate word matches between random sequences. **Sylvain Forêt** (Australian National University), Conrad Burden (Australian National University), Susan Wilson (Australian National University), Ruth Kantorovitz (Univ. of Illinois at Urbana-Champaign, USA) IC/MT1801/124

A simple and efficient way of comparing two sequences is to count the number of words of length k letters (k-words) that they have in common. This number, D_2, has been used for the clustering of large collections of EST sequences. One of the main advantages of sequence comparison using D_2 is its speed, the runtime being proportional to the size of the sequence under scrutiny. In contrast, alignment-based comparisons have a worst-case run time proportional to the square of the size. The rigorous study of the statistical distribution of D_2, has been an active area of research and asymptotic regimes of this statistic have been derived. Progress has also been made in the characterization of the distribution of approximate k-word matches.

In an effort to test the applicability of these recent theoretical advances to real data, we computed the D_2 optimal word size for various sequence lengths, for both perfect and approximate word matches. Kolmogorov-Smirnov tests indicate that D_2 has a compound Poisson distribution at the optimal word size for small sequence lengths (below 400 letters) and a normal distribution at the optimal word size for large sequence lengths (above 1600 letters). We find that the D_2 statistic outperforms BLAST in the comparison of artificially evolved sequences, and performs similarly to other methods based on exact word matches. These results, obtained with randomly generated sequences, are also valid for sequences derived from human genomic DNA. In most cases, the best trade-off between computational efficiency and accuracy is obtained with exact word matches. Given that our numerical tests have not included sequence shuffling, transposition or splicing, the improvements over existing methods reported here underestimate what may be expected for real sequences. Because of the linear run time and of the known normal asymptotic behaviour, D_2-based methods are most appropriate for large genomic sequences.

Qualitative response of interaction networks: application to the validation of biological models. **Anne Siegel** (IRISA Rennes, France), Michel Le Borgne (IRISA Rennes, France), Ovidiu Radulescu (IRISA Rennes, France), Carito Guziolowski (IRISA Rennes, France), Philippe Veber (IRISA Rennes, France) IC/MT1792/124

We advocate the use of qualitative models for the analysis of shift equilibria in large biological systems. We present a mathematical method, allowing qualitative predictions to be made of the behaviour of a biological system. These predictions are not dependent on specific values of the kinetic constants. We show how these methods can be used to improve understanding of a complex regulatory system.

More precisely, a biological system is modelled as an interaction graph that can be built from databases or directly extracted from the literature. Based on the above mathematical framework, we derive a large system of qualitative equations which is translated into a system of polynomial equations on a Galois field. We use this method to assess coherency between the model and different types of data, and perform model/data correction. This approach also allows determination of hubs of the regulation network on behavioural grounds; that is, it enables determination of the products whose influence propagates through the network so as to maximally constrain the system response.

This approach is illustrated on the interaction network of *E. Coli* and on the network of genetic regulation in fatty acid metabolism.

Anisotropic atomic motion in proteins: comparison of experiment with theory. **Conrad Burden** (Australian National University), Aaron Oakley (Australian National University) IC/MT976/124

High resolution X-ray diffraction crystallography is now capable of resolving anisotropic atomic motions in biological macromolecules. This information is included in Protein Data Bank records in the form of anisotropic temperature factors. From a theoretical viewpoint, proteins are also studied with Molecular dynamics (MD) simulations using empirical force fields. In this work we compare anisotropic atomic fluctuations in nanosecond-timescale MD simulations with those observed in an ultra-high-resolution crystal structure of the crambin protein. In order to make our comparisons, we have developed a compact graphical technique for assessing agreement between spatial atomic distributions determined by MD simulations observed anisotropic temperature factors.

Natural metrics for gene-microarray calibration. **Hans Binder** (Universität Leipzig, Germany) IC/MT1260/124

A variety of array-based technologies have been developed to study the transcriptional architecture of the genome by estimating the expression degree or the copy number of selected genomic regions. Microarray experiments aim at measuring in parallel the abundance of thousands of RNA-transcripts or DNA-copies by optical detection of their sequence-specific binding to surface-grafted oligonucleotide probes. Current applications range from global analyses of transcriptional programmes of different organisms over the establishment of novel criteria for the classification and prognostics of diseases to the accelerated discovery of drug targets. The actual chip generation enables the very detailed genome-wide screening with several millions of probe spots on each exon, tiling and SNP (single nucleotide polymorphism) array. The raw intensity data of the probe spots are unfortunately affected by parasitic interferences which in many cases prohibit the direct translation of the intensities into the concentrations of specific target-fragments. The calibration of probe sequence related intensity variation is therefore a fundamental prerequisite for the analysis of oligonucleotide microarray data. Current methods rely on multichip normalization techniques and reference arrays. We report a new method of data adjustment which corrects raw microarray intensity data for the effect of (i) sequence-specific affinities; (ii) mismatches; (iii) cross-hybridization and (iv) saturation. The hybridization model describes specific and non-specific hybridization in terms of a competitive two-species Langmuir isotherm and the formation of probe/target duplexes in terms of positional dependent base-pair interactions. The approach is based on a physically-motivated metric system for GeneChip data which uses intrinsic relations between matched and mismatches probes. This single-chip method allows normalization of the intensities of each array without referencing with respect to other chips.

IC/MP9/125: Control of drug variability: drug-intake behaviour and beyond.

Organiser: Fahima Nekka (Université de Montréal, Canada)
Co-organiser: Jun Li (Université de Montréal, Canada)

Poor adherence to treatment is a worldwide problem of striking magnitude that threatens efficacy of therapy. This problem is of particular importance in the case of chronic diseases. The drug-intake behaviour has been shown to be a major determinant in therapeutic variability. Because of its random features, the adherence can be described using stochastic and statistical methods to quantity its effect for optimization of drug administration strategy or other impacts. This event is aimed to gather various visions and approaches for drug intake behaviour, in terms of data acquisition and processing. Delineating the different sources of variability induced by the dosage forms, their drug intake behaviour and drug response will be an issue.

Challenging problems in pharmacometrics related to drug-intake behaviour. **Fahima Nekka** (Université de Montréal, Canada) IC/MT2045/125

The adherence problem refers, in a generic meaning, to any misuse of the drug. It includes compliance, which refers to the quality of execution of prescribed drugs, and persistence, indicating the time lapse before discontinuation of the drug. The predicted therapeutic outcome to a well designed drug regimen is inevitably deviated by the drug intake behaviour. Compliance in human medicine has an analogue in veterinary practice when drugs are administered through feed. Indeed, livestock exhibit a great variability in their access to medicated feed. It is important to characterize the impact of this source of variability on different therapeutic outcomes. Using a stochastic approach, we have mathematically formulated drug-intake behaviour in population of animals to which a medicated feed is administered, which we integrated within a pharmacokinetic modeling process. Through simulation and analytical approach, we succeeded in delineating the impact of each feeding behaviour pattern, regular and random, in terms of the characteristic features of the drug-concentration time course. We have also developed a pharmacokinetic formalism explicitly integrating the patient drug compliance. We have decomposed the drug concentration expressions into a principal component, represented as an infusion process, on which is superimposed an oscillation component, the latter including multiple dose information for different administration routes along with patient compliance. We have shown that variable compliance adds additional variation to the oscillation curve that we properly characterized. We also proposed categorizing the impact of compliance into different levels, expressed through different statistical moments of the drug concentration.

Role of PBPK, PK-PD modeling in drug discovery: opportunities and limitations. **Thierry Lavé** (Hoffman-La Roche, Switzerland) IC/MT2110/125

During drug discovery, considerable resources are required to assess the pharmacokinetic properties of potential drug candidates in vivo in animals and there is interest in optimizing the use of such testing by applying simulation.

Physiologically based pharmacokinetic (PBPK) models take in vitro and in silico data inputs and can predict concentration versus time profiles before any in vivo experiment is performed. If sufficiently reliable, such simulations could decrease the turnaround time for delivery of information to medicinal chemists during the optimization phase and could also be used to prioritize compounds for the more costly in vivo testing. In addition, these models combined with the safety and efficacy properties of the compound can be used during early discovery to define the key parameters to be optimized in the context of the target profile of the compounds.

While pharmacokinetics in the rat is obviously not of ultimate interest for the pharmaceutical industry there is evidence that PBPK models are superior to other more empirical methods for interspecies scaling and prediction of human pharmacokinetics. Thus a verified PBPK model in rat can be scaled to human to provide a basis for the rational selection of compounds for clinical development and if combined with a pharmacodynamic model allows prediction of the efficacy profile in human. Equally importantly, the mechanistic framework provided by a PBPK model can integrate all available predictive data on a compound and provide mechanistic insights into compound properties. Such integrative capabilities and mechanistic insights are not provided by the more commonly used non compartmental or compartmental analysis.

The results on the use of generic simulation prior to in vivo studies indicate that some caution is required since certain chemical classes are poorly predicted and it is recommended that generic PBPK models should only be applied for prioritization after verification of the simulations with in vivo pharmacokinetics for a few compounds of a given chemical class. Such verification will help to identify invalid model assumptions or missing processes where additional data is needed.

There is growing evidence that PBPK-PD models can already add value at various stages of the pre-clinical compound research and development process although one has to keep in mind a number of limitations. Their use is growing and the potential will be fully exploited as powerful and user-friendly software continues to make PBPK-PD models accessible to non-specialists.

A physiologically-based pharmacokinetic model to assess the role of ABC. **Frederique Fenneteau** (Université de Montréal, Canada), Jun Li (Université de Montréal, Canada), Fahima Nekka (Université de Montréal, Canada) IC/MT4384/125

Background: Drug interactions affecting the expression and/or activity of ATP-Binding Cassette (ABC) transporters may have a significant impact on drug disposition, drug effectiveness or drug toxicity. Hence, the ability to accurately predict drug disposition over a wide range of conditions of ABC membrane transporter activities is required to better characterize drug pharmacokinetics and pharmacodynamics. The physiologically based pharmacokinetic (PBPK) modeling, considered as a well established methodology in the field of risk assessment and environment studies is now progressively used at variant stages of drug discovery and development.However, existing PBPK models have not been designed to characterize distribution of ABC transporters drug substrates in tissues, mainly because of the restricted access to ABC transporters-related physiological data and parameters. The most studied ABC membrane transporter is P-glycoprotein (P-gp), a multidrug resistance (MDR) protein found to be expressed in normal tissues, such as the intestine, kidneys, liver, brain, testis, ovaries, placenta, and heart. These numerous locations suggest an important role for P-gp in drug absorption and excretion and in limitation of drug penetration into target tissues. Objective: The objective of this study was to develop an innovative modeling approach that takes into account the involvement of ABC transporter activities in different tissues to improve the prediction accuracy of drug disposition. Method: A PBPK model was developed in order to consider various conditions of P-gp transporters activities in mouse brain, liver, kidney and heart tissues. Drug distribution was represented either by variants of well-stirred model or permeability rate limited model. Input parameters related to the activity of P-gp in theses tissues were mainly extrapolated from in vitro data. About 500 multivariate log-normal Monte-Carlo simulations were also performed to account for the variability of model parameters and their influence on the following output parameters obtained on each tissue: Cmax, Clast and AUC0-tlast. The measure of input-output sensitivity was performed using the partial rank correlation coefficient (PRCC) concept which has been designed for correlated inputs. Results: Our drug distribution models were successfully validated from experimental data collected on wild type and mdr1a/1b(-/-) mice which were intravenously administered 5mg/kg of 3H-domperidone. PBPK model simulations provided mechanistic information on the involvement of ad-

ditional membrane transporters in drug distribution.The sensitivity analysis based on Monte-Carlo simulations and PRCC concept showed that the AUC, Cmax and Clast values predicted in heart, brain, liver, kidneys and plasma are mainly affected by in vitro parameters: PappBA, Km , fup and Vmax. In brain and heart tissue, the value of efflux or influx clearance due to additional transporters activity have an important role in the variability of the output parameters. Conclusion: The herein described PBPK model is novel and unique, while defined in general terms that can be applied to other drugs and transporters.

A pharmacokinetic formalism explicitly integrating the patient drug compliance. **Jun Li** (Université de Montréal, Canada), Fahima Nekka (Université de Montréal, Canada) IC/MT4389/125

The adherence phenomenon is now well recognized to seriously compromise drug efficacy. In this paper, we analyze the role of compliance through drug intake history as an integral part of the pharmacokinetic process. Being concerned with what is accessible in medical practice, we develop a stochastic approach to model the drug intake behaviour that we combine with a conventional pharmacokinetics model in order to investigate the effect of drug intake history on the pharmacokinetic time-course. For this purpose, we explicitly formalize the plasma concentration variations for the most common administration routes. This analytical approach allows to characterize drug concentration variations directly inherited from patient compliance.

IC/MP185/015: Dynamical systems approaches in neuroscience: theory, experiments, and applications.

Organiser: Robert Kozma (University of Memphis, USA)
Co-organiser: Yuzuru Sato (Hokkaido University, Japan)

Dynamical aspects of neuroscience gained significant popularity in recent years. The accessibility of new experimental tools (fMRI, high-resolution EEG and MEG) provide us with very deep and unprecedented insight into brain functions at cellular, population, and macro levels. The observed neural mechanisms show a rich variety of complex and self-organizing dynamics between stimulus and response. Neural correlates of higher cognitive functions have been identified and described in details, but a comprehensive and rigorous theory of neural functions is still missing. The available experimental data represent a great challenge to mathematical modeling and analysis of brain processes. New nonlinear mathematical and computational models (e.g., pulse-coupled neural networks, spiking neuron models, large scale multi-component statistical simulation models, and others) were developed in recent years that can be employed to analyze, interpret and explain the available data. The goal of this mini-symposium is to create a forum for researchers on the exciting research area of mathematical methods and applications of neurodynamics. We will discuss recent developments, and also outline perspectives for future activities. Leading experts in the relevant research areas will contribute to the interdisciplinary topics of the mini-symposium. These may include the following areas: (i) theoretical aspects and modeling of neurodynamics using various mathematical tools, as nonlinear differential equations, coupled map lattices, random cellular automata, neuropercolation and random graphs, liquid state machines, dynamic neural networks; (ii) description and interpretation of experiments with neural systems, like cellular and population level mechanisms of learning and memory, adaptation, high level cognitive functions; (iii) application of dynamical neuroscience principles in the design and implementation of artificially intelligent systems, as embodied intentional robotics, robot cooperation, control, and autonomy.

Oscillatory cortical network dynamics. **Steven Bressler** (Florida Atlantic University, USA) IC/MT3772/015

The mammalian cerebral cortex is organized as a large-scale network of distributed areas, each with a specialized pattern of connectivity. It has been proposed that cognitive function depends on the dynamic coordination of activity in sets of interconnected areas. Experimental evidence suggests that this coordination occurs by the phase synchronization of neuronal population oscillatory activity in the beta (13-30 Hz) and gamma (30-100 Hz) frequency ranges. Phase-synchronized oscillatory networks in the beta frequency range, as measured by spectral coherence, have been shown to be organized with respect to motor maintenance and visual anticipation in the sensorimotor and visual regions of cortex, respectively. Furthermore, the phase synchronized oscillations have been found to carry influences between neuronal populations of the networks, as measured by spectral Granger causality. The theory and significance of oscillatory cortical network dynamics will be discussed.

Beyond odour coding: oscillatory and behavioral dynamics in olfactory perception. **Leslie Kay** (The University of Chicago, USA) IC/MT3724/015

One of the most striking features of olfactory system physiology is odor-evoked fast oscillations, which represent varying degrees of underlying neural precision and coherence. Recent studies have shown that artificial ablation (in insects) of fast oscillations impairs and artificial enhancement (in mice) of this measure of global precision enhances discrimination of similar odorants. The true test of whether fast oscillatory precision plays a functional role in odor discrimination depends on whether individuals manipulate the level of oscillatory activity online in a task-dependent fashion. We show that rats do this such that fast temporal precision (gamma oscillation power) is significantly enhanced in difficult odor discrimination tasks, while it is unaffected in easy discrimination tasks. At the low end of the frequency spectrum are theta band olfactory bulb oscillations associated with inhalation and afferent drive to mitral cells. This slow coupling among principal neurons, characterized by a burst-like firing pattern, is disrupted when rats sniff at higher frequencies. However, during fast sniffing in odor investigation significant coherence at high theta frequency is found between the olfactory bulb and hippocampus in a performance-dependent fashion. These two sets of results suggest that fast and slow cooperative activity can operate simultaneously to serve different purposes, fast precision facilitating formation and recall of neural assemblies within a sensory area and slower theta-band coherence facilitating interregional cooperation in sensorimotor integration. Both of these modes are adjusted dynamically to respond to task demands. (Funding NIDCD R01DC00795)

A novel method of control using chaotic dynamics in systems having many degrees-of-freedom. **Shigetoshi Nara** (Okayama University, Japan) IC/MT3449/015

Chaotic dynamics in systems having many degrees of freedom are investigated from the viewpoint of harnessing chaos and is applied to complex control problems to indicate that chaotic dynamics has potential capabilities for complex control functions by simple rule(s). An important point is that chaotic dynamics generated in these systems give us autonomous complex pattern dynamics itinerating through intermediate state points between embedded designed attractors in high-dimensional state space. A key point is an idea that, with the use of simple adaptive switching between a weakly chaotic regime and a strongly chaotic regime, complex problems can be solved. As an actual example, a two-dimensional maze, where it should be noted that the set context is one of typical ill-posed problems, is solved with the use of chaos in a recurrent neural network model. Our computer simulations show that the success rate over sevral hendreds trials is much better, at least, than that of a random number generator. Our functional simulations indicate that harnessing of chaos is one of essential ideas to approach mechnisms of brain functions.

Modeling scale-free cortical dynamics using neuro-percolation approach. **Robert Kozma** (University of Memphis, USA) IC/MT2474/015

Critical properties of dynamical models of neural populations are studied. Based on the classical work of Renyi-Erdos on the evolution of random graphs, a new class of random cellular automata models called neuropercolation has been introduced in the literature. We analyze the properties on the neuropercolation model of the neuropil, the densely connected tissue in the cortex. We show the emergence of phase transitions in neuropercolation models at critical combination of several control parameters, including the level of external gain and noise, the density of long-range axonal connections (small-world phenomenon), and the sparseness of feedback between excitatory and inhibitory neural populations. Noise level and structural properties of the cortical tissue has been used to control the critical exponent, starting from white noise (slope 0) far away from criticality. The results show that scale-free power spectral density characterizes the dynamics near criticality, where exponent with a power exponent approaching -2. The results are interpreted in the context of recent experimental findings on the dynamics and structure of the cortex.

12: Bio-Mathematics, Contributed Talks

IC/CTS4631/12: **Other medical applications.**

Organiser: Eamonn Gaffney (University of Oxford, UK)

On numerical study of 2D periodically-forced internal flows. **Corina Alexandra Olah** (Université de Nantes, France) IC/CT560/015

Periodically-driven flows occur in several important applications such as flows in the blood circulatory system, the respiratory system, industrial mixers, etc. Despite their practical interest, relatively few literature is available on periodically driven flows, and several questions remain open: Under what circumstances a viscous flow driven by periodic boundary conditions ceases to be periodic? Which sequence of bifurcations transforms a periodic periodically-driven flow into a fully turbulent flow?

Even more striking is the fact that the existence of a solution for the weak formulation of the time-periodically forced Navier–Stokes equations, no matter how small is the viscosity or how large is the Reynolds number, has been known for a long time [1]. But the unicity and stability of that periodic solution is not guaranteed by the theorem. Few attempts at looking at the stability of periodically-driven flows have been done [2,3,4,5]. Those few studies show that periodic periodically-driven flows become unstable while increasing the Reynolds number.

The purpose of my work is to introduce and study the stability of simple time-periodically driven flows with a forcing induced by boundary conditions and to investigate the first bifurcation in 2D laminar pulsating flows. Another aspect is the investigation of the speed of convergence to a time-periodic solution, in case the time-periodic solution is stable, with two main types of periodic forcing, tangential and normal forcing on the boundary. Numerical results are presented for periodically-driven flows in a square cavity and the critical Re, at which a bifurcation occurs, is identified. Then, the experiments extend to stenosis, where a time-periodic condition is imposed at the inflow, in order to assess the parameters controlling the convergence to a time-periodic solution. Also, the results of some 3D simulations will be presented.

Work done in collaboration with Prof. Yves Bourgault, University of Ottawa, ON, Canada.

Numerical modeling of extra-corporeal shock-wave therapy. **Kirsten Fagnan** (University of Washington, USA), Randall LeVeque (University of Washington, USA) IC/CT830/125

Extracorporeal Shock Wave Therapy (ESWT) is a noninvasive technique for the treatment of a variety of musculoskeletal conditions such as delayed union of fractures, plantar fasciitis and calcified tendonitis of the shoulder. Shock waves were first used medically as lithotripsy (ESWL) to pulverize hardened calcified deposits such as kidney stones. The first application outside of lithotripsy was the treatment of calcifications in the shoulder since these deposits are similar to renal calculi. ESWT is also an effective treatment of non-unions, which are bone fractures that fail to heal over time. In lithotripsy, a shock wave is generated in a liquid bath, focused by a brass ellipsoidal reflector, and it then propagates into the body where it strikes the area of interest. Current numerical models are limited to simplified situations because the structure of the wave is highly nonlinear and therefore difficult to model with traditional finite difference and finite element techniques. We use high-resolution finite volume methods to capture this nonlinear behavior and model the shock wave propagation in bone and tissue by solving the nonlinear elasticity equations. This approach has been successfully applied to many problems in acoustic or elastic wave propagation in heterogeneous media.

We have obtained results in two- and three- dimensions by utilizing the CLAWPACK and CHOMBOCLAW software packages. CLAWPACK is a set of freely available Fortran routines de-

veloped by Randy LeVeque at the University of Washington. CHOMBOCLAW was written by Donna Calhoun as an extension of CHOMBO a freely available set of tools for solving equations using adaptive mesh refinement.

Mathematical and numerical modelling of focal ischemia. **Mauro Perego** (Politecnico di Milano, Italy) IC/CT4793/125

Relevance of a deep comprehension of the brain tissue damage mechanisms during focal ischemia has been realized since a long time. Besides the set up of therapies for stopping tissue degeneration in the ischemic penumbra, a possible outcome is the understanding of the failure of medical treatments that in other districts yield good results. For instance, fibrinolythic therapies, that works in the coronary districts, in the neurological context can lead to dangerous blood hemorrhages.

A possible approach for having a deeper insight of these phenomena is to resort to mathematical models and numerical simulations. The main difficulties in this context concern the intrinsic complexity of the phenomena and geometries at hand, that involve interacting fluid and biochemical dynamics, and the parameters identification and evaluation.

Numerical simulations presented in the literature are so far limited to 2D geometries and use a lumped average parameter to describe the cerebral blood flow, obeying an ordinary differential or an algebraic equation.

The aim of the present work is twofold. The first goal, is to give a rigorous model for the ions dynamics and include a space dependent description of the blood dynamics assuming that the vascular tissue is a porous medium. The second goal is to present numerical simulation of the phenomena at hand in 3D, by means of ad hoc finite element code.

The numerical results presented here show at a qualitative level possible dynamics that can be induced by the combination of biochemical events induced by the stroke and the reperfusion of the occluded vessels. The quantitative validation of the model used here is complicated by the difficulties in collecting experimental data. Nevertheless, it represents an important development of the present work.

Numerical simulations of low-energy defibrillation of the atria. **Monica Hanslien** (Simula Research Laboratory, Norway), Glenn Lines (Simula Research Laboratory, Norway), Joakim Sundnes (Simula Research Laboratory, Norway), Aslak Tveito (Simula Research Laboratory, Norway) IC/CT2239/125

Atrial fibrillation is the most common heart rhythm disorder, with possibly severe long-term complications for the patient. Strong electric shocks are known to cure fibrillation with high success rate, particularly those delivered by an implantable cardiodefibrillator (ICD). Although defibrillation has been subject to a great extent of research for many years, the phenomenon is yet poorly understood. We believe that numerical simulations can help understanding what is observed in medical experiments. Unfortunately, with today's technology and knowledge of defibrillation, the shock strength needed to terminate fibrillation is known to cause intolerable pain to the patient. Also, the recurrence of atrial fibrillation is frequently observed. It is therefore of the utmost interest to seek methods of intracardiac defibrillation that allows for lower shock strength, and to find the optimal placement and the number of electrodes used in the configurations.

We address these issues in the present talk. In particular we investigate the effect of such low-energy shocks on the atria, delivered through several electrode configurations, and of different strengths. We show results of bidomain simulations on a realistic geometry of the entire atria, using sophisticated numerical methods.

Modelling mucoiliary flows. **Eamonn Gaffney** (University of Oxford, UK) IC/CT2778/125

Mucociliary fluid flows are ubiquitous in nature, playing important roles in the lung, the ovaries and the ear. However, the quantitative details of such flows are poorly understood. In the lung cilia drive mucus towards the trachea. The cilia beat in a very thin, stratified liquid consisting of a basal Newtonian layer known as the periciliary fluid (PCL), and an upper mucus layer.

A model of mucociliary transport has been constructed which incorporates both mucus viscoelasticity and the effects of beating cilia. This provides, inter-alia, a physical basis for the observation in pseudo-hypoaldosteronism that excessive mucus hydration leads to increased mucus transport, via a thicker, less viscous, mucous layer. We have additionally demonstrated that empirical observations of microbead transport in in-vitro models of mucociliary flows need not correlate to the flow profile suggested by experimental scientists, due the effects of mixing and diffusion perpendicular to lung epithelium.

Organiser: Diana Rubio (Universidad National de General Sarmiento, Argentina)

A 1D inverse problem with interfaces in bio-engineering. **Diana Rubio** (Universidad National de General Sarmiento, Argentina), María Troparevsky (Buenos Aires, Argentina) IC/CT3459/015

In this work we study a 1D Inverse Problem that is motivated by the electroencephalogram (EEG) problem, which consists in the use of EEG data to find the location of electric sources of neural activity in the brain. The problem is described by a Poisson type equation with interfaces, since the patient's head is modeled as nested layers. The elliptic equation has discontinuous coefficients due to the different conductivity values for the brain, skull and scalp.

In a previous work presented at ICNPAA 2006, a simple 1D model of the problem was considered to illustrate theoretical and numerical aspects of the computation of sensitivities. Here, we present some ideas to develop a numerical scheme to approximate the solution to the Inverse Problem for the 1D model for the case of a pointwise source. It is our intention to use these ideas to face the 3D Inverse Problem in a near future.

Multiple folding and packing in DNA modeling . **Francesca Maggioni** (Università degli Studi di Milano Bicocca, Italy), Renzo Ricca (Università degli Studi di Milano Bicocca, Italy) IC/CT3139/010

By using a new set of kinematic equations (see Maggioni & Ricca, *Proc. R. Soc.* A **462**, 2006) we study geometric and energetic aspects associated with multiple folding and coiling of elastic filaments for DNA modeling. By these equations we demonstrate that high degree of coiling may be achieved at relatively low energy costs through appropriate writhe and twist distribution, and independently from the number of coils formed. For sufficiently high twist we show that coiling is actually favoured by elastic energy relaxation, when the deformation energy is purely due to filament curvature and mean twist. We also determine the packing rate associated with filament compaction in the case of a hierarchical helical coiling. These results find useful applications in modeling DNA wrapping in proteic regions, where there is a strong connection between high coiling, efficient compaction and energy localization.

Wing disc size and robustness of Dpp gradients. **Frederic Wan** (UC Irvine, USA) IC/CT4235/015

A reaction-diffusion system of partial differential equations that accounts for the biological processes at work in the Drosophila wing imaginal disc essential for signaling decapentaplegic (Dpp) gradient formation is examine to investigate the effect of the epical-basal height of cells on the shape of signaling gradients. Our principal result is the relation between the epical-basal cell height and magnitude and shape of signaling Dpp gradient along the anterior-posterior axis of the wing imaginal discs. The result is used to delineate the effect of wing disc size in maintaining the shape of a normal signaling gradient and thereby the robustness of the normal development of the organism.

Acknowledgment: The research is supported in part by NIH grants P20GM66051 and R01GM067247. The research of Nie and Wan is also supported by NIH Grant R01GM075309. The two NIH R01 grants are awarded through the Joint NSF/NIGMS Initiative to Support Research in the Area of Mathematical Biology.

Understanding the anti-body mutation process by mathematical methods. **Lei Zhang** (Humboldt-Universität zu Berlin, Germany) IC/CT1423/124

A very important phenomenon observed in immunity is the antibody affinity maturation that leads to an efficient recognition of an invading pathogen during infection. Germinal centers are the major sites for antibody production, mutation and selection. In order to understand the underlying mechanisms during the mutation process, we developed simple mathematical models to analyze the available DNA sequence data derived from germinal centers (GCs) of the immunized mice. First, we calculated the frequencies of observed mutations in antibody sequences and compared them with theoretical predictions calculated from positional mutability and type of mutation. Our theoretical result not only confirmed the two known key mutations found experimentally, but also records 32 others positively selected mutations. This result suggests that an effective antibody binding may be a result of additive effects of positively selected mutations rather than a few large effects by key mutations. Also, we further identified 19 negatively selected mutations, which may represent harmful mutations whose harboring cells are eliminated rapidly by programmed cell death. Second, although it is not possible to follow the development of individual GCs by experimental means, mathematical modelling provides insights into the antibody maturation process in time. Our results suggest a much shorter history of mutation process in comparison with previous predictions. Such implications may change our current understanding on the underlying mechanisms of antibody mutation.

Stability analysis of a tritrophic food-chain model. **Jean Tchuenche** (University of Dar es Salaam, Tanzania) IC/CT35/121

The study of three-species communities have become the focus of considerable attention, and since ecological communities studies starts with its food web, we consider a tritrophic food chain mode comprised of the prey, the predator and the super-predator. The classical assumption of the domino effect is replaced by an adaptive parameter. Dynamical behaviours, boundedness, bifurcation, as well as stability are analyzed. Practical implications are explored and related to real populations.

Individual-based modelling of chlamydial infection. **Daniel Mallet** (Queensland University of Technology, Australia), Kel Sutton (Queensland University of Technology, Australia), David Wilson (University of New South Wales, Australia) IC/CT3208/012

Chlamydia is amongst the most common sexually transmitted diseases in the world and when left untreated, may lead to infertility and numerous other conditions. Currently, most mathematical modelling in the literature regarding Chlamydia is based on time dependent differential equations. In this work, we include spatiotemporal considerations of the progression of chlamydial infection in the genital tract. This novel direction is achieved using cellular automata modelling with probabilistic decision processes. In this presentation, the modelling strategy will be described, as well as its relationship with existing models and the advances in understanding that are achieved with such a model.

Spatio-angular modeling for the formation of oriented patches in chondrocytes cultures. **Viviana Palumberi** (Universität Basel, Switzerland) IC/CT4489/120

In cell therapy applications, the use of cytokines during cell expansion has been proposed as a promising method to increase the number of cells that can be obtained starting from a small tissue biopsy. In particular specific growth factors have been recently shown to enhance AHAC proliferation rate of adult human articular chondrocytes (AHAC) expanded in monolayer. We have recently developed a model combining time-lag (delay) and logistic equations (LDDE) to capture the non-instantaneous and asynchronous growth of the AHAC for the entire culture time. The delay model was found not only to fit very well the experimental growth curves, but also to confirm the value of some important kinetic parameters. In this study, we are devising a new mathematical model which involves spatio-angular cell-cell interaction coupled with logistic growth. As the cell population evolves, AHAC can change their orientation and position either randomly, or in response to neighboring cells. Experimentally, we observed that when the cells in culture reach a critical level, they spontaneously tend to align along a common axis of orientation. The selection of a preferred axis of orientation stems from the fact that the uniform steady state could be unstable under particular conditions. The model describes the evolution of the cell density in time, space and orientation. The computer simulations require the numerical solution of the integro-partial differential equations that we performed by the moment with a combination of Runge-Kutta method, finite differences and Trapez rule. Our results indicate that we can trust the linear stability analysis, although it cannot predict exactly the behavior of the nonlinear model. In the future, we would like to perform experiments to get some of the parameter values and to check if our mathematical model can predict at least the qualitative behavior of the cells.

Cardiac computations and operator splitting. **Achim Schroll** (Lund universitet, Sweden), Aslak Tveito (Simula Research Laboratory, Norway), Glenn Lines (Simula Research Laboratory, Norway) IC/CT4386/123

During past 10 years [simula.research laboratory] has developed software to simulate the electrical activity of the human heart. Applications of the simulator include: The hearts performance under normal and pathological conditions, predisposing factors for arrhythmias and prospective drug treatments as well as mechanisms of electrical shocks (defibrillation).

Mathematically, the problem is formulated as a system of coupled partial and ordinary differential equations. The ODE system models electro-chemical processes in cardiac cells and recent models tend to be very complicated. This stiff ODE system is nonlinearly coupled to a time dependent reaction-diffusion equation. The complexity of the coupled system makes a straightforward fully implicit approach virtually impossible. That is where operator splitting applies: In an iterative approach the ODE part is step-by-step separated form the PDE part of the model.

The topic of this presentation is to investigate the error of operator splitting applied to the fully coupled discrete model. Under appropriate assumptions, our analysis shows that operator splitting does not reduce the order of convergence of the numerical method. Hence, splitting is an efficient solution technique for the discrete model. Moreover, the ordering of the splitting matters. The error is less if the diffusion step is performed after the reaction step instead of vice versa.

The talk presents joint work with the scientific computing group at Simula, in particular Glenn T. Lines and Aslak Tveito.

The effect of rivers on japanese knotweed *dispersal.* **John Ward** (Loughborough University, UK) IC/CT4498/121

Japanese Knotweed (*Fallopia japonica*) is a highly invasive, rhizomal plant, native to eastern Asia, that has become a major problem in Europe, USA, Canada and New Zealand since their artificial introduction. These plants aggressively displace native species, taking over habitats and reducing biodiversity. Furthermore, their rhizomes (underground stems) are capable of damaging buildings and roads. Management of these plants is made very difficult due to the capability of very small rhizomal fragments to grow and quickly regenerate a knotweed patch. This makes eradication difficult, as the entire rhizome network needs to be removed. Moreover, fragments are easily transported by rivers and canals, which greatly enhances their rate of spread along banks and into new areas.

In this talk, we start by discussing briefly the results of a model of rhizomal spread using a correlated random walks, which motivates the use of Fisher's equation to model events over large time and space scales. These ideas are extended to model the effect river flow on enhancing knotweed expansion both up- and down-stream. By a suitable rescaling, the model reduces to a system consisting of coupled PDEs governing land knotweed density and river fragment density. Travelling wave solutions are investigated in the 1-D case and expansion speeds are determined in terms of the model's parameters with interesting results. Finally, 2-D simulations will be presented to illustrate the impact of river-borne spread.

Geometrical and haemodynamical risk factors for internal carotid artery aneurysm development. **Tiziano Passerini** (Politecnico di Milano, Italy) IC/CT4794/125

The presence of a cerebral aneurysm produces changes in the haemodynamic behaviour of pathological arteries and is related to a non physiological distribution of mechanical stress on the arteries wall. In the context of the ANEURISK project (http://www2.mate.polimi.it:8080/aneurisk) we exploited fluid dynamical analysis of blood flow inside real vascular geometries: these have been reconstructed starting from 3D angiographical images provided by the Department of Neuroradiology of Niguarda Hospital (Milano, Italy). Our goal is to find distinctive morphological and mechanical features related to the risk of development of the pathology.The Navier-Stokes problem in these real vascular geometries is solved numerically with an edge stabilization approach. A realistic (non stationary) flow rate is imposed on the inlet sections through suitable Dirichlet conditions; on the outlet sections we exploit homogeneous Neumann conditions. Different boundary conditions based on the so-called "geometrical multiscale approach" will be addressed too. Post-processing computations lead to the evaluation of dynamical and kinematical quantities such as mechanical stress on the vascular wall and particle trajectories inside the fluid domain.We focus on ICA (internal carotid artery) and find statistical correlations between anatomical and functional features and the presence or absence of aneurysms. A classification of vascular districts is obtained, based on a combination of geometrical (ICA radius, curvature, tortuosity) and fluid-dynamical (wall shear stress, flow vorticity, particle residence time inside aneurysm sac) characteristics. The final goal is to find a risk index, stating the probability of pathology development for arteries belonging to each these classes.

Applications of fuzzy decision making in diabetes. **Venkateshwari Gandhi** (Madurai, India) IC/CT4995/125

Diabetes is a life long disease, thus increasing the morbidity and mortality and decreasing the quality of life. At the same time, the disease and its complications cause a heavy economic burden for the diabetic patients and the society. In this paper, clustering of the diabetic patient is done based on the symptoms such as frequent urination, excessive thirst ,extreme hunger, unusual weight loss, increased fatigue, irritability, blurry vision etc.. The data of the diabetic patient is got from the hospital and from questionnaire. After clustering the patients, fuzzy decision making is considered by which the right remedies can be given to the right patients.

A bidomain threshold model of intracellular calcium release. **Ruediger Ruediger Thul** (University of Nottingham, UK), Stephen Coombes (University of Nottingham, UK) IC/CT2296/010

We introduce a bidomain threshold model of intracellular calcium release. By the explicit construction of travelling wave solutions we are able to probe the dependence of wave speed on physiologically important parameters, including the rate of calcium pumping between the endoplasmic reticulum and the cytosol. Importantly we develop a linear stability analysis that predicts the onset of front instabilities, leading to the emergence of waves that propagate in a back-and-forth manner. Direct numerical simulations are used to confirm our travelling wave predictions.

Parallel numerical methods for inferring phylogenies. **Nelson Borges** (Instituto Militar de Engenharia, Brazil), Felipe Albrecht (Instituto Militar de Engenharia, Brazil) IC/CT4725/124

In recent years there has been increased interest in producing large and accurate phylogenies trees using some numerical computing approaches. The construction of accurate trees for a large number of taxons requires a computational load increase and thus parallel computing can be helpful[1,2]. We work with distance matrix methods for inferring phylogenies when a large number of taxons is considered. These methods have been introduced by Cavalli-Sforza and Edwards[6] and by Fitch and Margoliash[7] , having given rise to other methods, as those developed by Wolf Y.I. *et al.*[4], Clarke G.D. et al. [3] and Grishin N.V. *et al.*[5]. Cavalli-Sforza methods are associated to a system of linear equations whose dimension grows up linearly with the number of taxons. Here, we use parallel computing to get a lower time processing when solving the associated weakly coupled linear systems. Different iterative methods were performed and compared.

Stochastic binding of Ca^{2+} *in the dyadic cleft: continuous vs. random-walk description of diffusion.* **Johan Hake** (Simula Research Laboratory, Norway), Glenn Lines (Simula Research Laboratory, Norway) IC/CT3311/122

It is a common understanding that diffusion in signaling micro domains cannot be described properly by a deterministic and continuous model. Several recent publications claim that as the number of participating particles in these volumes goes down, the deterministic description becomes invalid or does not make sense and Random walk (RW) methods have to be employed. We simulate the Ca^{2+} dynamics in a small volume in a myocyte continuously and deterministically by a coupled system of reaction-diffusion equations, and also with a fully stochastic RW model and we stochastically simulate the event of a single Ca^{2+} ions binding to single receptors in both models. The distributions of the bind events from the RW model are used to test the goodness-of-fit of the equivalent distributions predicted by the continuous model, using Kolmogorov-Smirnov tests. We find that the bind distributions from the continuous model fit the collected bind events from the RW simulations. Our results show that if a stochastic model is used for single Ca^{2+} ions binding to receptors in small subcellular volumes, a deterministic and continuous model of the reaction-diffusion dynamics in the actual volume can be used. In our study we also present a novel model for evaluating the stochastic event of a diffusing molecule binding to a stationary or mobile receptor based on a macroscopic rate law. The model is analytical and the accuracy is therefore not dependent on the time step.

The walk of myosin V: a kinetic model. **Rebecca Hoyle** (University of Surrey, UK) IC/CT1312/122

Molecular motors are proteins or protein complexes that transform chemical energy into mechanical work on a molecular level, generating forces and leading to motion. Myosin V is a processive molecular motor involved in intracellular transport that is found in many animal cell types and is particularly plentiful in neurones. It has two heads that attach to an actin track, and a long neck region that attaches to its cargo, such as vesicles and organelles. The coordinated binding and release of the myosin heads to actin result in a walking motion along the track, fuelled by the hydrolysis of ATP.

The precise details of how the biochemical reactions and mechanical motions of the two head elements engineer effective processive molecular motion along actin filaments remain unresolved. In our model (and others) the walk is broken down into substeps and ODEs are given for the time-dependent probability of a myosin molecule being in each of the corresponding substates. We consider five basic states augmented by two others that allow for futile hydrolysis and detachments. We compare the outcomes with experimental results for run lengths, velocities, and dwell times and their dependence on ATP and ADP concentrations and external loads (from attached cargo) in both directions. The model reveals how myosin-V can use the internal strain in the molecule to synchronise the motion of the head elements.

A powerful new feature of our approach is that estimates for the rate constants in the reaction cycle and the internal strain energy are obtained by a computational comparison scheme involving an extensive exploration of a large parameter space. We use simulated annealing to minimise a cost function based on the deviation of our results from experimental data, exploiting the fact that we have obtained analytic results for our reaction network; e.g., for the velocity but also the run length, diffusion constant and fraction of backward steps. The agreement with experiment is often reasonable but some open problems are highlighted, in particular the inability of such a general model to reproduce the reported dependence of run length on ADP concentration. The novel way that we explore parameter space means that any confirmed discrepancies should give new insights into the reaction network model.

Our approach could be used in future to differentiate between competing theoretical models of the myosin-V stepping cycle and indeed between those of other translatory molecular motors, such as kinesins, dyneins and other members of the myosin family.

This work was done in collaboration with Karl I. Skau, formerly of the Department of Mathematics, University of Surrey, UK and Matthew S. Turner of the Department of Physics, University of Warwick, UK.

Nonlinear dynamics of a double bilipid membrane. **Christine Sample** (Northwestern University, USA), Alexander Golovin (Northwestern University, USA) IC/CT2017/122

The nonlinear dynamics of a double biological membrane that consists of two coupled lipid bilayers, typical of some intracellular organelles such as mitochondria, is studied. A phenomenological free-energy functional is formulated in which the curvatures of the two parts of the double membrane are coupled to the lipid densities. The derived system of coupled nonlinear evolution equations for the double membrane dynamics is studied analytically and numerically. The linear stability analysis is performed and the domain of parameters is found in which the double membrane is stable. For the pa-

rameter values corresponding to an unstable membrane we perform 2-D numerical simulations that reveal various types of complex dynamics.

IC/CTS4641/12: Ecology, epidemiology.

Mathematical models of fish populations in marine reserves. **Lev Idels** (Malaspina University, Canada) IC/CT4419/121

Marine reserve areas (MRAs) have been proposed as an efficient tool for maintaining a sufficient stock whereas providing a buffer against severe overfishing in the remaining unprotected areas. Based on nonlinear systems of delay differential equations, we build a realistic model of MRAs that incorporates age-structure, migration (dispersal), fishing mortality, variable harvesting rates, and the effects of time delays. In contrast to earlier models, our model is relatively general and may be used to depict a wide variety of circumstances regarding MRAs.

We studied global stability and complex dynamics with perennial ecological favourites such as sign stability, permanence and persistence. The study of the combined effects of periodically varying environment and periodic harvesting rates on the fish population in the reserves will provide practical guidance for specific fishery decisions, e.g., combination of MRAs and seasonal restrictions.

Stability and oscillations of a nutrient–plant–herbivore system with delayed nutrient recycling. **Kalyan Das** (P.P. Poddar Institute, India) IC/CT3614/121

In this paper we consider a mathematical model of a resource Ũbased plant-autotroph-herbivore system with a discrete delayed nutrient recycling and incorporating the average number of herbivores attacking the plants follow the Holling type -II function.we have studied the growth of autotroph and herbivore population depending on the limiting nutrient which is partially recycled through decomposition.It has been shown that the supply rate of external resources play an important role in shaping the dynamics of the autotroph-herbivore system.We have derived the conditions for asymptotic stability and switching to instability of the steady state.The length of the delay preserving the stability has also been derived.Finally,all the analytical results are interpreted ecologically.

Nonlinear models for the effect of pollutants on population with time-delay. **Jamal Hussain** (Mizoram University, Tanhril, India) IC/CT866/121

With rapid pace of industrialization, urbanization, deforestation etc. our environment is getting polluted day by day. The effects of pollution, caused by various human activities on ecosystems have been studied by several researchers. In particular, Parra-Guevara and Skiba (2003) studied the effects of pollutants and control of pollutants emissions. They assumed that a portion of the pollutants emitted to the atmosphere is subjected to various chemical reactions and as a result, a part of a primary pollutant is transformed into other substances (secondary pollutants), which can be more toxic than the original one. But in the above studies the effect of time lag has not been considered. In this regard, Rescigno (1977) studied the effect of precursor pollutant on single species, but he did not consider the rate of uptake concentration of the pollutant on the growth of the species. Further in the above studies the effect of diffusion has not been considered. Keeping the above in view, in this paper we propose and analyse the effect of a pollutant on a population, which is living in an environment polluted by its own activities. It has been assumed that the pollutant enters into the environment not directly by the population but by a precursor produced by the population itself. It has been further assumed that the larger the population, the faster the precursor is produced, and the larger the precursor, the faster the pollutant is produced. The model has been studied with and without diffusion. In the case of no diffusion it has been shown that population density settles down to its equilibrium level, the magnitude of which depends upon the equilibrium levels of the emission and washout rates of pollutant as well as on the rate of precursor formation and its depletion. It has been noted that the rate of precursor formation is crucial in effecting the population. It has further been noted that if the concentration of pollutant increases unabatedly, the survival of the population would be threatened.

The effect of diffusion on the interior equilibrium state of the system has also been investigated. It has been shown that if the positive equilibrium of the system without diffusion is globally asymptotically stable, then the corresponding uniform steady state of the system with diffusion is also globally asymptotically stable. It has further been noted that if the positive equilibrium of the system with no diffusion is unstable, then the corresponding uniform steady state of the system with diffusion can be made stable by increasing diffusion coefficients appropriately. Thus, it has been concluded that the global stability is more plausible in the case of diffusion than the case of no diffusion.

In case of conservation model, it has been shown that if the rate of formation of the precursor pollutant is controlled by some external means, its effect on the population can be minimised.

Numerical Simulations are also carried out to validate the models developed.

Biological control through provision of additional food to predators: a theoretical study. **Srinivasu Pichika** (Andhra University, India), Prasad Bhuvanagiri (Andhra University, India), Venkatesulu Mandadi (University of Missouri, USA) IC/CT975/121

In this article we analyze a variation of a standard predator-prey model with type II functional response which represents the predator-prey dynamics in presence of some additional food to the predator. The aim is to study the consequences of providing additional food on the system dynamics. We conclude that handling times for the available foods play a key role in determining the eventual state of the ecosystem. It is interesting to observe that by varying the quality and quantity of additional food we can, not only control and limit the prey but also limit and eradicate the predators. In the context of biological pest control, the results caution the manager on the choice of quality and quantity of the additional food used for this purpose. An arbitrary choice may have opposite effects leading to increase in pest concentration and eradication of the predator. From this study it is possible to develop management strategies that manipulate quality of the additional food and its supply level for the benefit of biological control. The theoretical conclusions agree with results of some practical biological control experiments.

Mathematical modelling on harmful algal blooms in the presence of toxic substances. **Samares Pal** (RKM Vivekananda Centenary College, India) IC/CT730/121

Plankton is the basis of the entire aquatic food chain. Phytoplankton, in particular, occupies the first trophic level. Plankton performs services for the Earth: it serves as food for marine life, gives off oxygen and also absorbs half of the carbon dioxide from the Earth's atmosphere. The dynamics of a rapid (or massive) increase of plankton populations is an important subject in marine plankton ecology and generally termed as a 'bloomŠ. There has been global increase in harmful plankton in last two decades and considerable scientific attention towards harmful plankton has been paid in recent years.

The model that we propose has three interacting components consisting of the non-toxic phytoplankton (NTP), herbivorous zooplankton (Z) and toxin producing phytoplankton (TPP) with an additional factor that the release of toxic substance by toxic-phytoplankton species reduces the growth of zooplankton.

To establish the theoretical results we shall use our field observations. We consider the toxin producing plankton (TPP) species as Noctiluca scintillans, non-toxic phytoplankton (NTP) species as Coscinodiscus sp. and zooplankton species as Paracalanus sp. Our field study suggests that when TPP is absent the equilibrium level of NTP is much lower than the value observed when TPP is present. Moreover the equilibrium level of zooplankton decreases when TPP is present. This phenomenon depicts the fact that the presence of TPP in the system enhances the production of NTP and reduces the zooplankton grazing pressure. Further, the biomass distribution observed in our field study demonstrate that introduction of TPP leads to the persistence of all the species through reduction of blooms and can be used as controlling agent for stability of marine ecosystem. Our analytical as well as numerical study reveals the essential mathematical features regarding the role of TPP in phytoplankton-zooplankton interaction.

On selective harvesting of an inshore–offshore fishery: a bioeconomic model. **Kripasindhu Chaudhuri** (Jadavpur University, India) IC/CT456/121

In the present paper, a bioeconomic model is developed on the selective harvesting of a single species inshore-offshore fishery, assuming that the growth of the species is governed by the Gompertz law. Our motivation for introducing the Gompertz law primarily lies in the superiority of the Gompertz law over the logistic law. Since ideal living conditions prevail in the initial stage, there should be very rapid growth initially. Thereafter, as the population grows, the limitation of resources forces the growth rate to decline and the population gradually approaches the saturation level. Compared to the logistic law, the Gompertz law exhibits faster early growth, but a slower approach to the asymptote, with a longer period of linear growth about the point of inflexion.

When the fish population size becomes considerably large, it tends to maintain a strong pressure on the newly produced biomass through cannibalism which is more effective on larger egg-aggregates formed by overcrowding of eggs in a large fish population. Also, there will be intraspecific competition amongst the individuals in the population for the use of limited resources available in the habitat. These effects, coupled together, should retard the growth of the population to a large extent and as a result, the population size should approach its asymptote rapidly as in the case of the logistic model. These retarding effects are, however, counterbalanced to some extent by group movement which is a special behavioural characteristic of a fish population. As a result, the approach of the population size to the asymptote is slowed down. This peculiar feature of faster early growth and slower approach to the asymptote is reflected in the Gompertz law of growth. Moreover, implications of exploiting a biological population obeying the Gompertz law of growth have been studied very little. This fact also motivated the author to develop the present model.

The dynamical system governing the fishery is studied in depth. The local as well as global stability of its non-trivial steady state is examined. Existence of a bionomic equilibrium is established under different parametric considerations. The optimal harvest policy is discussed by invoking PontryaginŠs Maximal Principle. Lastly, the results are illustrated with the help of a numerical example.

IC/CTS4636/12: Tumor and cardiac modelling.

Organiser: Graeme Wake (Massey University, New Zealand)

Multiscale modelling of fluid transport in tumours. **Rebecca Carter** (University of Oxford, UK), Jon Chapman (University of Oxford, UK) IC/CT4280/123

The success of therapeutic agents in treating cancer is limited by their inability to reach their target *in vivo* in adequate quantities. Rapid cell proliferation rates and a lack of functioning lymphatics in tumours result in a poorly organised vasculature and an increased interstitial fluid pressure, limiting delivery of drugs to malignant cells and causing the development of hypoxic (oxygen deprived) and necrotic regions. To fully exploit anticancer drugs it is crucial to understand and overcome the physiological *barriers* to their penetration.

With this in mind, we aim to develop a comprehensive mathematical model for the transport of blood through a tumour. We assume the tumor has a periodic microstructure and consider a *unit cell* made up of blood vessels and surrounding tissue. Blood is treated as a Newtonian fluid and the high permeability of tumour capillary walls is captured using Starling's Law to model the extravasation of fluid from the capillary into the interstitium. We solve the flow problem on this local scale and use multiple scales to drive the effective equations describing the blood transport on the tumour scale. Similarly we incorporate convection and diffusive drug transport to give effective equations that describe the distribution of the drug throughout the tumour.

Modeling the migration of cancer cells in the bloodstream. **Keng Hwee Chiam** (IHPC, Singapore) IC/CT1144/122

We model the migration of cancer cells that have broken away from a tumor and are circulating in the bloodstream. Using the immersed boundary method and culling from literature the material properties of cancer cells, we simulate how cells deform as a function of the flow properties of the bloodstream as well as the adhesive properties between the cancer cells and the endothelial cells of the bloodstream. We also simulate the migration characteristics as a function of the migrating cell density. From these, we calculate rough approximations of the metastatic rate and efficiency. Finally, we speculate on how our discrete cell modeling approach can be connected to continuous modeling approaches of tumor growth.

Functional differential equations arising in cell-growth models. **Graeme Wake** (Massey University, New Zealand) IC/CT4810/123

In the course of developing generic models of the evolution of cell cohorts simultaneously undergoing growth and fission, which are structured by size (here taken as DNA content), we have encountered an unusual class of functional differential equations. The solution of these possess the behavior described as a "steady-size distribution(SSD)", where the size distribution is constant in shape, but not magnitude, as time evolves. These equations do not fit easily into established theory as there is a distinct lack of general theory of non-local differential equations. Yet the non-local character is exactly what determines the occurrence, asymptotically with time, of SSD-like behavior. These equations are shown to have solutions which are candidates for probability distributions by a range of techniques. This means identifying the eigenvalues of a singular, non-local, eigenvalue problem. The SSD-like behavior is usually globally attracting, but this is not yet established in general. These models describe actual cell-population cohorts and the match with data of tumor cells (in-vitro data) is excellent. The model can be changed to describe the cohort evolution under tumor treatment and to assess the effectivenes of cancer therapy. The latter, by switching off the non-local term in the equations, destroys the SSD-like behaviour. This work is being extended to models incorporating non-linear growth effects. Work done in collaboration with Ronald Begg and Bruce van-Brunt (Massey University), Bruce Baguley and Elaine Marshall (University of Auckland), and Britta Basse and David Wall (University of Canterbury). The support of the NZ Institute of Mathematics and its Applications by the award of a Maclaurin Fellowship during the current part of this work is gratefully acknowledged.

Thin-film modelling of bacterial swarming. **Eleanor Norris** (Loughborough University, UK), John Ward (Loughborough University, UK) IC/CT4505/010

Swarming is a term used to describe the rapid spread of bacterial colonies on a moist semi-solid substrate. The phenomenon is cell density dependent and usually occurs in response to low nutrient levels. Swarming plays an important part in many bacterial infections, including wound infections and septicaemia as well as lung infections in, for example, cystic fibrosis patients. We aim to develop an understanding of the processes involved in bacterial swarming with the eventual aim of using this knowledge to compare different treatment strategies. Our work involves developing a model of swarming bacteria constrained within a thin film. The equations describing the biological mechanisms determining the behaviour of the bacteria are coupled with the standard thin-film reduction of the Navier-Stokes equation (which describes the action of the biosurfactant on the fluid boundary). The initial results of this modelling will be presented, along with a comparison of these results with the available experimental data.

IC/CTS4642/12: Other medical applications.

Organiser: Martin Frank (TU Kaiserslautern, Germany)

Clustering the individuals using similarity measure by their life style. **Kameshwari Meenakshi Sundaram** (Thiagarajar College of Engineering, India), Venkateshwari Gandhi (Madurai, India), Velu Lakshmana Gomathi Nayagam (NIT Tiruchirappalli, India) IC/CT3890/125

Diseases caused by the life style are becoming a huge burden to the society. To cure these diseases, the study about the life style of the individual is needed. The patients affected by the same life style may need same remedies. The life style of them has been studied by the questionnarie. Questionnarie contains the criterias such as workload, familial background etc. The information from the individuals would be in Intuitionistic Fuzzy linguistic terms such as high, low, normal, fair , good etc. Those Intuitionistic Fuzzy linguistic terms are converted to Intuitionistic Fuzzy Number using the dilation and concentration properties of Intuitionistic Fuzzy set by fixing one of the linguistic terms as F. Similarity measure has been found out by using the Euclidean distance measure. By defining equivalence relation the individuals are clustered. A medical practitioner can then counsel or give remedies to these clustered individuals.

Keywords: Intuitionistic Fuzzy Set, Similarity measure , Euclidean distance in Intuitionistic Fuzzy setup, Intuitionistic Fuzzy Number,Dilation ,Concentration.

Travelling-wave behaviour in a multiphase model of a population of cells in an artificial scaffold. **Greg Lemon** (University of Nottingham, UK) IC/CT4763/125

In this talk I will discuss travelling-wave behaviour in a recently-formulated multiphase model for the growth of biological tissue in the context of tissue engineering. In suitable limits, tissue growth in the model is shown to occur in the form of travelling waves that can propagate either forwards or backwards, depending on the values of the parameters. In the case where the drag force between the cells and the scaffold is non-zero, the growth can be analysed in terms of the propagation of a constant-speed wavefront in a semi-infinite domain. A shooting method is described for numerically calculating the wave speed, and results for how the speed varies with respect to the parameters are given. In the case where the drag force is zero, the size of the aggregate of cells is shown either to grow or to shrink exponentially with time. I will also give some asymptotic results of the convergence to the travelling wave solutions. The results presented in this talk may be of importance in determining the experimental factors that control tissue invasiveness in scaffolds thereby allowing greater control over engineered tissue growth.

Work done in collaboration with Professor John King.

Toward fast and accurate deterministic models for dose calculation in radiotherapy. **Martin Frank** (TU Kaiserslautern, Germany) IC/CT1008/125

A deterministic Boltzmann transport model for dose calculation in electron radiotherapy is presented. We investigate several ways to simplify the deterministic model having two goals in mind: lower computation times on the one hand, high accuracy and model inherent incorporation of tissue inhomogeneities on the other hand. While being fast, the second property is lost in the often used pencil beam models. Several test cases, including the irradiation of a water phantom, are presented.

Identification of muscle determinant for different gait speeds by proper orthogonal decomposition. **Sirod Sirisup** (National Electronics and Computer Technology Center, Thailand), Rumpa Boonsinsukh (Srinakharinwirot university, Thailand) IC/CT1108/015

In this investigation, we explore the use of the proper orthogonal decomposition (POD) on electromyography (EMG) of the leg muscles, with the objective of elucidating the musclesŠ behavior for each gait speeds. Four different gait speeds were used in the study: slow, comfortable, faster and fastest walking. The electromyographic data used in this study were recorded from 12 bilateral lower limb muscles: tensor fascia latae (TFL), semitndinosus (ST), vastus medialis (VM), rectus femoris (RF), tibialis anterior (TA) and medial gastrocnemius (MG). Results indicate that the primary muscles for slow walking were bilateral TFL which act alternately to accept weight bearing on each leg. The same muscles also show another dominant function when working simultaneously in pelvic stabilization. In addition, we found that when the speed of walking increases, the number of muscle determinants for gait has been added. This study emphasizes that the POD method is the novel method to identify the energy-efficient gait such that comfortable walking is the most energy-efficient gait, whereas fastest walking consumes the highest energy.

A drug–drug interaction parameter-estimation problem, II. **Bruno Bieth** (Purdue University, USA), Raymond Chin (Indiana University & Purdue University, USA), Lang Li (Indiana University, USA) IC/CT779/125

A two drug interaction is usually predicted by individual drug pharmacokinetic. An innovative drug-drug interaction prediction method based on a three-level hierarchical Bayesian meta-analysis model is developed that includes a Monte Carlo Markov chain pharmacokinetic parameter estimation procedure. Underlying the parameter estimation procedure is a fast integration method of the stiff pharmacokinetic equations. In this presentation, we report the results of the fast integration method on the system of stiff pharmacokinetic equations. We also discuss the interrelation and interaction between the Monte Carlo Markov chain pharmacokinetic parameter estimation procedure and the numerical integration scheme.

12: Bio-Mathematics, Posters

IC/PP4390/012: **Theoretical vs. experimental analysis of neurogenesis models.**

Presenter: Yanthe Pearson (Rensselaer Polytechnic Institute, USA)

Normally, the growth of neuronal processes is highly regulated, with temporally-controlled initial outgrowth followed by regular cycling between phases of extension and retraction as the processes navigate toward their targets. Ethanol delays the initial outgrowth of axons and dendrites, but the dynamics of subsequent growth are altered in rather specific ways. We apply stochastic techniques through mathematical modelling of this biological process with an emphasis on the axons spatial behaviour, under certain conditions. Current experimental studies use time-lapse microscopy of live embryonic rat hippocampal neurons, growing in cell culture, to study the dynamics of axonal and dendritic growth and the consequences of the disruption of their growth, by the use of ethanol. We choose to explore such phenomenon for several reasons, those of which include assisting biologists in providing them with approximations through sophisticated quantitative analysis of their experiments, as well as a means to explore methods for future studies, biological and/or other disciplines. Our approach includes careful analysis of data, by various methods, those of which include filtering, inverse techniques, Markov chain methods, as well as noise reduction and time series analysis. We then introduce simple stochastic models, based on variables defining the axons movement; these models are studied both numerically and analytically, as a means to capture the phenomenology underlying the axons internal and external mechanisms, as well as to acquire and compare parameter estimates.

IC/PP4790/010: **Coupled calcium and cell-cycle dynamics in radial glial cells.**

Presenter: Duncan Barrack (University of Nottingham, UK)

Radial glial cells give rise to neurons via asymmetric division during the embryonic development of the brain and communicate via ATP mediated calcium waves, with ATP being released into the extracellular space as the cell approaches S phase of the cell cycle. ATP then binds to the $\mathrm{P2Y_1}$ receptors of radial glial cells, leading via a G-protein cascade to the release of calcium from internal stores. Internal calcium transients have the effect of increasing the production of Cyclin D, a key regulator of cell cycle progression. This coupling is thought to locally synchronise cell cycles, so that clusters of cells proliferate together, shedding cells in uniform sheets.

There are various models for the cell cycle and for intracellular calcium dynamics. We present a model that couples the calcium and cell cycle dynamics in a radial glial cell. We then use a combination of direct simulation and numerical continuation of periodic solutions to study the effect of this coupling on the period of the cell cycle. When cells in a 1D lattice communicate via the diffusion of extra-cellular ATP, a phase averaging technique shows that this spatial coupling can lead to the phase locking of the cell cycles. We consider how this synchronous behaviour depends upon different parameter regimes. For example, we consider a regime where cells are intrinsically cycling, as well as regimes where cells are quiescent (i.e., not cycling) until an initiating ATP pulse leads to the release of calcium in that cell, inducing it to enter the cell cycle and leading to a propagating calcium wave with concomitant effects on the cell cycle throughout the lattice of cells. We also look at how stochastic calcium events affect the local synchronisation of the cell cycle.

IC/PP1685/010: **Gene-regulatory networks and delay-differential equations.**

Presenter: Arcady Ponosov (Universitetet for Miljø- og Biovitenskap UMB, Norway)

A mathematical framework to study gene regulatory networks with time-delay effects, which is based on delay differential equations, is suggested and outlined. An essential feature of the gene regulatory networks is their “almost Boolean” structure, where the dynamics are governed by sigmoid-type nonlinearities which are close to the step functions. This is due to the fact that genes are only activated if certain concentrations are close to the respective threshold values. The delay effects arise from the time required to complete transcription, translation and diffusion to the place of action of a protein. Compared to biomolecular reactions with a typical time scale of seconds or fractions of a second, these processes are slow: it may take several minutes or even hours from the binding of the transcription factor to the promoter until the transcription

and translation process is finished.

Any mathematical model describing such networks faces a problem of how to study the dynamics in the vicinity of the thresholds. A method of localizing stationary points and local stability analysis near the thresholds in the presence of delays is offered. The basic technical tools, which are systematically applied within the suggested framework, combine a special modification of the well-known “linear chain trick" with the perturbation analysis.

Some properties of gene regulatory networks with delay in comparison with the non-delay model are discussed as well.

The results are illustrated by a number of examples.

Acknowledgment. The work is partially supported by CIGENE - Centre for Integrative Genetics at the Norwegian University of Life Sciences.

IC/PP4711/015: Modelling planar cell polarity.

Presenter: Sabine Schamberg (University of Nottingham, UK)

Planar Cell Polarity (PCP), the phenomenon of whole fields of cells being polarised in a plane, is a common feature in insects and mammals. Typical examples are the alignments of scales, hairs, feathers or bristles. The animal most studied in this context is the fruit fly *Drosophila*. In this work we concentrate on its wings in which every cell elaborates a hair that points distally. Although the mechanism of PCP is still not completely understood, the core proteins have been found and some theoretical studies have been conducted. Since a lot of biological details are included into these models they tend to be rather complex and therefore difficult to analyse mathematically. Hence our aim is the development of alternative simplified models and the simplification of already existing ones, which facilitates their analysis. In this work, we present two such approaches.

The first one is a simplified model in one spatial dimension. Here, we consider a row of cells, whereby each cell has two sides with a certain amount of activity (corresponding to accumulation of certain PCP proteins) on each side. The activity in a cell is then moved back and forth in that cell depending on the amount of activity in the neighbouring cells. The more activity there is on the adjacent side of the next cell, the more is moved away from the present side to the other one within the same cell. In addition the amount that is moved depends on the level of concentration on the present side. This mechanism results in polarisation of the cells, which in certain cases is even propagated as a wave. The speed of this wave depends on the rate of impact of the neighbouring cells on the present cell. This approach can be extended to arrays of square or hexagonal cells in two spatial dimensions.

Furthermore we analyse the model proposed by Amonlirdviman *et al.* (*Science, 307:423-426, 2005*). This consists of a system of reaction-diffusion equations, which describe the interactions of the core proteins in a field of two-dimensional hexagonal shaped cells. The polarisation is driven by two main mechanisms: a negative feedback loop and an intrinsic spatial bias. In order to perform a numerical steady state analysis of this approach we have simply considered the one space dimensional case and assumed that, similar to the simplified model discussed above, we have a row of cells in which each cell has two sides, a left and a right one. These investigations revealed that PCP can be achieved without the intrinsic bias, provided there is an initial intracellular inhomogeneity which can be amplified.

IC/PP7/121: Effect of age-based vaccination policy on the dynamics of delay epidemic model.

Presenter: Sumit Banerjee (JSS Academy Of Technical Education, India)

The spread of communicable diseases depend on rate of transmission or contact rate, removal rate, mode of transmission , latent and incubation period, age Ű specific susceptibility and immunity of individuals to the disease . The immunity to the specific disease in the individuals can be artificially developed with the help of vaccination. It is understood that the vaccination leads to complete protection and vaccinated individuals are immune but this is not true and in general vaccination only leads to partial protection. The role of latent period in the dynamics of communicable diseases is also an important factor and should be considered in the epidemic models. Further, while studying age-structured epidemic models, maturation period should also be considered in the model, because in the case of several infectious diseases the populations of certain Age Ű groups are immune from diseases for some finite period and after that they become susceptible.

In view of the above, therefore, in this paper a delay epidemic model has been studied to investigate the effect of age Ű based vaccination policy on the dynamics of a communicable disease incorporating latent period and maturation delay. For the model, the disease-free and endemic equilibrium points have been obtained and their local and global stability analysis have been carried out .

IC/PP4354/121: Parasitoids may act as bodyguard for maize plant by attacking pests: a mathematical model.

Presenter: Guruprasad Samanta (Department of Mathematics, Bengal Engineering and, India)
Co-author: Alakes Maiti (Presidency College, Kolkata, India)

Maize (*Zea mays*) is an important food crop world-wide and *Spodoptera* sp. (e.g., fall armyworm *Spodoptera frugiperda*) are important pests of this. The farmers have to suffer from heavy economic losses due to these pests. In this paper, we have examined the usefulness of natural enemies from the viewpoint of the plant fitness. We have considered a tritrophic model consisting of maize plant, pest and parasitoid to analyze the field observations. The effect of time-delay on the tritrophic model is studied. Numerical simulations are carried out to illustrate our mathematical findings. The implications of our results are discussed critically.

IC/PP2016/122: Modelling macromolecular transport in the interphase cell nucleus.

Presenter: Annika Wedemeier (German Cancer Research Center, Germany)
Co-author: Joerg Langowski (German Cancer Research Center, Germany)
Co-author: Willi Jaeger (Universität Heidelberg, Germany)
Co-author: Holger Merlitz (Xiamen University, PR China)
Co-author: Mario Mommer (Interdisziplinäres Zentrum für wissenschaftliches, Germany)

In recent years great progress has been made in the view of the living cell as a regulatory network in time. However, a quantitative description of the transport of biomolecules in the dense macromolecular network of chromatin fibers in the interphase cell nucleus is still missing. Furthermore, it is not yet clear to what extent macromolecular mobility is affected by structural components of the nucleus.

This work contributes to the understanding of this process by developing a theoretical description of network diffusion in the interphase cell nucleus. To model the situation in the cell nucleus a lattice approach is used minimizing computational time and effort. Our model leads to a quantitative understanding of transport behaviour which is directly related to chromatin morphology. Changes of these characteristics are known to occur upon apoptosis or malignant transformations.

The crowded environment of chromatin fibers in the nucleus is simulated by a simplified version of the bond fluctuation method originally desrcibed by Carmesin et al (Macromolecules 1988,21, p.2819) in combination with a Metropolis Monte Carlo procedure. This yields well equilibrated polymer chains satisfying static properties such as end-to-end distance.

It is investigated how the diffusion coefficient of particles of a given size depends on the 3D geometry of the network of chromatin fibers and their density in the nucleus. We show that the diffusion cofficient is proportional to the volume fraction of the freely accessible space. Additionally, we investigate to what extent structural properties of the fibers, such as persistence length and contour length, influence the diffusion coefficient. We observe that neither the contour length nor the persistence length of the fibers affects the diffusional transport of small particles.

Furthermore, we found that the translational diffusion of the mass centers of the chromatin fibers is anomalous.

The concentration of the biomolecules in the cell nucleus over time is predicted by an analytical reaction-diffusion model. The diffusion coefficients of this system are fitted to the results obtained by the numerical lattice approach.

IC/PP4760/123: Finite-element analysis for radio-frequency ablation of infarcted cardiac tissue.

Presenter: Jacques Beaumont (Binghamton University, USA)
Co-author: Ying Sun (Binghamton University, USA)
Co-author: Fan Zhou (SUNY Binghamton, USA)

Radiofrequency (RF) ablation is the treatment of choice for cardiac arrhythmias occurring in myocardial infarction. While preferred over drug treatment, RF ablation presents a number of risks, especially microexplosions and severe bleeding due to excessive heating. Our goal is to optimize the parameters of RF ablation in order to produce a minimal amount of damage while still preventing the formation of micro-reentrant circuits within the infarcted zone. To this end, we have developed a finite element (FE) model of myocardial infarcts and RF induced tissue damages. The model provides means by which noninvasive cardiac imaging data can be used to determine optimal parameters of RF ablation. Our thermo-electric coupled FE model has two innovative elements. First, it takes into consideration both perfused and non-perfused tissue (multizone) encountered in an infarcted area and how RF changes this distribution in time. Second, it incorporates a realistic geometry of the infarct including isthmuses by which impulses can reenter. Solving the thermo-electric coupled problem, we determine the lesion size during ablation. A RF stimulation with a power of 10W-35W is investigated for various penetration depths, infarct geometries, blood perfusion rates, and operation periods. We found that the blood perfusion can significantly reduce the maximum tissue temperature and lesion size, and hence lower the possibility of microexplosions and blood coagulation. The lesion grows rapidly at the very beginning of the operation and slows down as it reaches quasi-steady state. The results indicate that a 20W stimulation of 100s can produce a lesion large enough to prevent most micro-reentrant circuits located near the surface. However, blocking conducting pathways deep inside the infarct may need extra power input. With appropriate experimental validations, we plan to utilize our model to determine optimal parameters for RF ablation, and investigate artificial perfusion needed for interventions.

IC/PP3179/015: Instabilities in biochemical reaction networks.

Presenter: Maya Mincheva (University of Wisconsin, USA)

Understanding interactions in complex biochemical reaction networks of genes, proteins and enzymes is an important problem in modern cellular biology. Mathematical models of biochemical reaction networks are usually large systems of coupled nonlinear differential equations with many unknown parameters, making direct numerical simulations practically impossible.

On the other hand, important properties of these systems are determined only by the network's structure, and do not depend on the unknown parameters. We describe how a bipartite graph associated with a biochemical reaction network can be used to predict its dynamical properties, such as multistability and oscillations, usually referred to as instabilities. This analysis generalizes the positive/negative feedback cycle conditions for instabilities.

In more general models, the instabilities can be caused by diffusion or delays. Similar network conditions relate the structure of the same bipartite graph to delay-induced or diffusion-driven phenomena, such as oscillations or Turing instability respectively.

The proposed method is suitable for computerization, which will enable the analysis of large biochemical networks with incomplete kinetic data.

13: Physics and Electrical Engineering, Minisymposia

IC/MP3896/010: **Path integrals, classical waves, quantum waves, and modern mathematical asymptotics, II: coherent state representations, novel mathematical extensions, and computational, seismic, and electromagnetic applications.**

Organiser: Bair Budaev (University of California, Berkeley, USA)
Co-organiser: Louis Fishman (MDF International, USA)

Ever since Feynman's ground breaking path integral formulation of quantum mechanics in the 1940's, path integrals have played an increasingly important role in quantum field theory, condensed matter physics, mathematics, and classical physics and engineering applications. This minisymposium will examine path integrals and their applications from the perspective of the correspondence between classical wave propagation, quantum mechanical wave propagation, and the development of modern mathematical asymptotics. Coherent state constructions will be discussed. Novel mathematical extensions will be presented. A Feynman–Kac-type stochastic formulation for the Helmholtz equation will be developed and applied in electromagnetic modeling. Applications to seismic wave propagation and imaging, and electromagnetic modeling will be discussed. The design of a specific computing architecture for the rapid evaluation of path integrals will also be addressed.

Envisioning light: software-assisted research in optical singularities. **Michael Berry** (University of Bristol, UK) IC/MT1098/011

Singularities of fields of light rays and waves of light are increasingly recognized as fundamental in optics. In exploring these singularities, mathematical software has played a central role, in computation and in visualizations that have led to the discovery of new phenomena.

At the geometrical level, the singularities are caustics— surfaces on which focusing occurs. Waves decorate these with rich interference patterns, whose finest structures are new singularities, namely singularities of phase (a.k.a. nodal lines, or optical vortices, or wave dislocations). The vector nature of light introduces further singularities, associated with polarization.

Many phenomena are best understood and illustrated in terms of singularities: rainbows, tsunamis, polarization fingerprints in the blue sky, the complexities of crystal opticsĚ

Wiener-measure regularized path-integrals: the right mathematics, the right physics. **John Klauder** (University of Florida, USA) IC/MT959/010

Feynman's formal phase-space path integral lacks physical as well as mathematical meaning. Insertion of a regularizing factor leading to a Wiener measure on phase space, coupled with a limit outside the integral in which the diffusion constant diverges, gives the integral both mathematical and physical meaning. For diffusion on a plane (or a sphere, or a pseudosphere), the result is a propagator expressed in a coherent-state representation appropriate to canonical (or spin, or affine) kinematics. Adoption of the Stratonovich midpoint rule leads to a well-defined path integral that is covariant under canonical coordinate transformations. With a well-defined path integral in hand, suitable semiclassical asymptotics may be developed.

A multi-scale approach to one-way wave propagation. **Maarten de Hoop** (Purdue University, USA) IC/MT3695/010

Starting from a Trotter product representation, we develop a multi-scale approach to one-way wave propagation derived from dyadic parabolic decomposition in phase space. The associated thin-slab propagator is related to a pseudodifferential operator. We obtain an expansion of the thin-slab propagator revealing a separation of variables in phase space reminiscent of the generalized-screen expansion. We discuss various numerical aspects.

Joint research with H. Smith (UW), G. Uhlmann (UW), F. Andersson (Lund).

Numerical implementation of seismic wavefield operators via path integrals. **Michael Lamoureux** (University of Calgary, Canada), Gary Margrave (University of Calgary, Canada) IC/MT2915/010

The seismic imaging problem centers around mathematical and numerical techniques to create an accurate image of the earth's subsurface, using recorded data from geophones that capture reflected seismic waves. Using a path integral approach, a wavefield extrapolater can be expressed as a limit of depth-sliced path steps through a variable velocity medium. An image is created from the correlation between upward and downward going waves. We report on the mathematical issues that arise in implementing numerical algorithms based on the path integral approach, in particular convergence, stability, and accuracy.

IC/MP160/010: **Path integrals: classical waves, quantum waves, and modern mathematical asymptotics, I: phase-space constructions, convergence issues, and seismic and electromagnetic applications.**

Organiser: Bair Budaev (University of California, Berkeley, USA)
Co-organiser: Louis Fishman (MDF International, USA)

Ever since Feynman's ground breaking path integral formulation of quantum mechanics in the 1940s, path integrals have played an increasingly important role in quantum field theory, condensed matter physics, mathematics, and classical physics and engineering applications. This minisymposium will examine path integrals and their applications from the perspective of the correspondence between classical wave propagation, quantum mechanical wave propagation, and the development of modern mathematical asymptotics. Phase space constructions will be discussed, and their connections to wave propagation and inverse scattering algorithms displayed in detail, for both the cases of one- and two-way wave equation modeling. The role of path integrals in electromagnetic modeling will be reviewed. Mathematical convergence issues will be discussed, along with a presentation of applications to seismic wave propagation and imaging.

Probabilistic approach to wave propagation. **Bair Budaev** (University of California, Berkeley, USA), David Bogy (UC Berkeley, USA) IC/MT2063/010

The similarity between the Helmholtz and Schrödinger equations creates opportunities for extending the ideas conceived in quantum mechanics to wave propagation and vice versa. Thus, ray theory of wave propagation brought transparent asymptotic solutions to some problems of quantum physics, while path integrals associated with the Schrödinger equation provided theoretically exact solutions to problems of wave propagation which lead to an insightful alternative view of ray theory. The advantages of such cross-fertilization become especially valuable when methods originating from different areas are combined to compensate the deficiencies of each method by the strengths of the counterparts.

Here we discuss a novel approach to wave propagation which combines the ideas of ray theory with the technique of path integration. This approach starts similarly to ray theory, from the representation of the solution of the Helmholtz equation as a product of the amplitude and the oscillating exponent of the eikonal, which is computed by a canonic technique of analytic mechanics. However, unlike in ray theory, the amplitude is not approximated by the exact solution of the approximate first-order transport equation, but instead, the amplitude is considered as the solution of the complete transport equation which is exactly equivalent to the original Helmholtz equation. Then the complete transport equation is solved by the probabilistic Feynman-Kac formula based on the path integral with respect to the Wiener stochastic measure associated with the heat-conduction equation, which is much better suited for computations than the path integral associated with Schrödinger equation.

This approach to wave propagation is shown to be an effective tool for the analysis of numerous wave propagation problems some of which are notoriously difficult for standard methods, and the proximity between the Helmholtz and Schrödinger equations makes it natural to expect that the advantages of the method are not restricted to wave theory, but will also find useful application to quantum mechanics.

Path integrals as analysis on path space by time-slicing approximation. **Naoto Kumano-go** (Kogakuin University, Japan) IC/MT1640/010

In 1948, R.P. Feynman expressed the integral kernel of the fundamental solution for the Schrödinger equation, using the path integral. The path integral is a new sum over all paths. Feynman explained the path integral as a limit of the finite dimensional integral which is now called the time slicing approximation. Furthermore, Feynman suggested a new analysis on a path space with the functional integration and the functional differentiation. However, in 1960, R. H. Cameron proved that the measure of the path integral does not exist mathematically. Therefore, using the time slicing approximation, we treat the path integral as an analysis on a path space by a mathematically rigorous discussion.

Samplers for the Feynman–Kac or Onsager–Machlup formulas. **Cristian Predescu** (University of California, Berkeley, USA) IC/MT4165/130

In chemical physics, the Feynman–Kac formula is utilized to evaluate quantum effects by path integral Monte Carlo simulations. The Onsager-Machlup formula provides the sampling distribution for a Smoluchowski process, albeit the Feynman-Kac formula can be utilized to the same effect. In both cases, there is there need for Monte Carlo samplers capable of coping with the critical slowdown that appears when the number of path variables becomes large because of accuracy requirements or large transit times. I shall present the fast sampling algorithm and the sliding and sampling procedure, which are capable of addressing these issues to various degrees.

Helmholtz path integrals. **Chad Hogan** (University of Calgary, Canada), Louis Fishman (MDF International, USA) IC/MT4984/130

The multi-dimensional, scalar Helmholtz equation plays a prominent role in modeling both classical (acoustics, electromagnetics, optics, seismics) and quantum mechanical wave propagation phenomena. In 1948, Feynman introduced the path integral representation for the fundamental solution of the (one-way) Schrödinger equation of non-relativistic quantum mechanics. These coordinate and phase space, functional integral solutions provide a convenient global statement of the wave propagation process, identify important physical quantities, connect to an underlying stochastic foundation, and naturally lead to computational algorithms. Corresponding path integral constructions for the Helmholtz equation are complicated by the inherently two-way nature of this *elliptic wave propagation* problem.

This talk will briefly review several different approaches to the construction of Helmholtz path integrals. After a concise review of the Feynman path integral constructions for the Schrödinger equation, the Feynman/Fradkin representation, based on the imbedding of the n-dimensional Helmholtz equation in an $(n+1)$-dimensional Schrödinger equation, will be examined. This will lead naturally to the approximate Feynman/Garrod path integral representation for the Helmholtz equation. The application of the Liouville representation and the Feynman-Kac formula will then follow. Changing direction, the exact, well-posed, one-way reformulation of two-way, elliptic wave propagation problems, based on the Dirichlet-to-Neumann operator and corresponding phase space path integral constructions, will be reviewed. Subsequently, these solution representations will be contrasted with the corresponding coordinate space path integral construction, the Feynman/DeWitt–Morette representation, and its connection to a possible new class of stochastic processes. Finally, application to seismic imaging/inversion will be briefly addressed.

FIO-product representation of solutions to symmetrizable hyperbolic systems. **Jérôme Le Rousseau** (Université de Provence Aix-Marseille I, France) IC/MT2653/010

Let $n, k \in \mathbb{N}^*$. We consider a first-order Cauchy problem:

$$\partial_z u + a(z,x,D_x)u = 0\,, \tag{1}$$

$$0 < z \le Z \;u\,|_{z=0} = u_0\,, \tag{2}$$

with $Z > 0$ and $a(z,x,\xi)$ a $k \times k$ matrix with entries continuous with respect to z with values in $S^1(\mathbb{R}^n \times \mathbb{R}^n)$ and $u = (u_1, \ldots, u_k)^t$, with the usual notation $D_x = \frac{1}{i}\partial_x$.

The matrix symbol $a(z,x,\xi)$ is assumed symmetrizable, in the sense that

$$a_1(z,x,\xi) = L(z,x,\xi)\alpha_1(z,x,\xi)(L(z,x,\xi))^{-1},$$

where $L(z,x,\xi)$ is a $k \times k$ invertible matrix with Lipschitz regularity with respect to z with values in $S^0(\mathbb{R}^n \times \mathbb{R}^n)$, and $\alpha_1(z,x,\xi)$ decomposes into $\alpha_1(z,x,\xi) = -i\beta_1(z,x,\xi) +$

$y_1(z,x,\xi)$ where both β_1 and y_1 are $k\times k$ Hermitian matrices that commute and can be smoothly diagonalized (e.g. in the case of constant multiplicities). We require $y_1(z,x,\xi)\geq 0$. The Cauchy problem is then hyperbolic and well-posed, with the initial data u_0 in any Sobolev space.

We define the *thin-slab* propagator, $\mathcal{G}_{(z',z)}$, $0\leq z\leq z'\leq Z$, to be the operator with kernel

$$G_{(z',z)}(x',x) := \frac{1}{(2\pi)^n}\int e^{i\langle x'-x|\xi\rangle}e^{-\Delta a_0(z,x,\xi)}e^{-\Delta a_1(z,x',\xi)}\mathrm{d}\xi,$$

with $\Delta = z'-z$, and prove it is a Fourier integral operator (FIO) with matrix phase of order 0.

We introduce the following Ansatz to approximate the solution operator: for $\mathfrak{P}=\{z^{(0)},z^{(1)},\dots,z^{(N)}\}$ a subdivision of $[0,Z]$ with $0=z^{(0)}<z^{(1)}<\cdots<z^{(N)}=Z$ such that $z^{(i+1)}-z^{(i)}=\Delta_{\mathfrak{P}}$, the operator $\mathcal{W}_{\mathfrak{P},z}$ is

$$\mathcal{W}_{\mathfrak{P},z} := \begin{cases} \mathcal{G}_{(z,0)} & \text{if } 0\leq z\leq z^{(1)},\\ \mathcal{G}_{(z,z^{(k)})}\prod_{i=k}^{1}\mathcal{G}_{(z^{(i)},z^{(i-1)})} & \text{if } z^{(k)}\leq z\leq z^{(k+1)}. \end{cases}$$

Let $s\in\mathbb{R}$ and assume $u_0\in(H^{(s+1)}(\mathbb{R}^n))^k$. We prove that, if the matrix symbol $a(z,.)$ is of Hölder regularity with respect to z, the Ansatz $\mathcal{W}_{\mathfrak{P},z}$ converges to the solution operator, $U(z,0)$, of the Cauchy problem (1)-(2) in operator norm in $L((H^{(s+1)}(\mathbb{R}^n))^k,(H^{(s+r)}(\mathbb{R}^n))^k)$ as $\Delta_{\mathfrak{P}}$ goes to 0 with a convergence rate of order $\alpha(1-r)$, $0\leq r<1$,

$$\|\mathcal{W}_{\mathfrak{P},z}-U(z,0)\|_{((H^{(s+1)})^k,(H^{(s+r)})^k)}\leq C\Delta_{\mathfrak{P}}^{\alpha(1-r)},\quad z\in[0,Z].$$

In the case $r=1$ we have strong convergence. The solution to (1)-(2) can thus be written as the result of the action of an infinite product of FIOs on u_0.

We shall connect this result with path integration and will provide applications and numerical examples in seismology.

Feynman operator calculus on Banach spaces I: basic theory. **Tepper Gill** (Howard University, USA) IC/MT3385/010

In order to extend our constructive representation theory of Feynman's operator calculus to Banach spaces, we use a result of Gross and Kuelbs, which shows that all separable Banach spaces may be rigged between two Hilbert spaces as dense continuous embeddings. We then construct continuous tensor product Banach spaces along the lines used by von Neumann to construct continuous tensor product Hilbert spaces. We then present a number of new results on operator extensions, which allow us to lift our representation theory from the Hilbert space to the Banach space setting. We then construct time-ordered integrals for general contraction semigroups.

Feynman operator calculus on Banach spaces II: generation theory. **Woodford Zachary** (Howard University, USA) IC/MT3380/010

We provide a general theory of time-ordered evolution operators on Banach spaces. First, we extend the general theory of operator semigroups to the time-ordered setting and prove a few of the generation theorems, including the famous Hille-Yosida Theorem. We then unify the theory of time-dependent hyperbolic and parabolic evolution equations. We extend the Dyson expansion to the Banach space setting and provide a general theory for the interaction representation of relativistic quantum theory. In addition, we provide a strong generalization of the Feynman-Kac formula for path integrals on Banach spaces.

IC/MP320/015: Non-local electrostatic effects in liquid crystals: fibers and elastomers.

Organiser: Carme Calderer (University of Minnesota, USA)
Co-organiser: Patricia Bauman (Purdue University, USA)
Co-organiser: Daniel Phillips (Purdue University, USA)

In the last decades, optic applications of nematic liquid crystals have met an enormous success in display manufacturing, including large video devices. This motivated a lot of activity in the mathematics community, especially in studies of calculus of variations, defects and flow problems.

The discovery and synthesis of new types of liquid crystals has also brought up new questions in modeling and analysis. New materials include the molecular *banana-shape* liquid crystals and the elastomers. The former are characterized by the ferroelectric behavior and belong to the class of smectic phases, with higher ordering than nematic. This combined with their liquid nature results in their manifestation as filaments of complicated shapes and respond to electric fields in a nonlocal fashion.

Liquid crystal elastomers are solids that combine mathematical features of nonlinear elasticity and those of standard liquid crystals. In particular, their gel states are of interest in application to soft tissue. Some of such materials are also biaxial in the bulk. The presentations will deal with models and analysis of ferroelectricity, biaxiality, filament stability, elastomers and gel states. One of the lecutures will address the optic properties of negative index materials found in chiral liquid crystals.

Stable bent-core liquid fibers. **Daniel Phillips** (Purdue University, USA) IC/MT3336/0

We consider a model for drawn fibers formed from cylindrical, smectic layers of banana-shaped liquid-crystal molecules. The molecules' shape induces both a spontaneous polarization and a distinctive effect on layer density. These features lead to a model that predicts stable fiber formation. We analyze solutions from this model and their electro-magnetic properties. This is joint work with C. Bailey, P. Bauman, and C.Calderer.

Adaptive-grid methods for Q-tensor theory of liquid crystals. **Alison Ramage** (University of Strathclyde, UK) IC/MT3681/015

In addition to the defect core structure, the dynamics of defect movement is also a crucial issue for liquid crystal cells. Previous numerical simulations of such effects have mostly involved using standard finite difference or finite element techniques on uniform grids, and have often been based on using director theory rather than the $\mathbf{Q}$-tensor approach proposed here. However, the presence in the physical problem of characteristic lengths with large scale differences (the size of the defect is very small compared to that of the cell) suggests that more sophisticated numerical modelling techniques could be used to great effect. One obvious approach is to use an adaptive grid technique, ensuring that there is no waste of computational effort in areas where there is no need for a fine grid. Adaptive grid methods have been successfully used to solve PDEs in many branches of computational mathematics such as computational fluid dynamics, mathematical biology, semiconductor modelling and aerospace engineering. In this talk we will present an introductory study of the use of adaptive grid methods for solving PDE problems in $\mathbf{Q}$-tensor theory of liquid crystals. This work is in collaboration with Dr Christopher J. Newton of Hewlett-Packard Laboratories in Bristol, UK.

Landau–de Gennes theory of isotropic–nematic–smectic liquid crystal transitions. **Paolo Biscari** (Politecnico di Milano, Italy) IC/MT3744/0

We propose a new version of Landau-de Gennes variational theory fit to simultaneously describe isotropic, nematic, smectic-A, and smectic-C phases of a liquid crystal. The unified description allows us to deal with systems in which one, or all, of the order parameters develop because of the influence of defects, external fields and/or boundary conditions. We derive the complete phase diagram of the system, that is, we characterize how the homogenous minimizers depend on the value of the constitutive parameters. The coupling between the nematic order tensor and the complex smectic-A order parameter generates an elastic potential which is a non-convex function of the gradient of the smectic order parameter. This lack of convexity yields in turn a loss of regularity of the free-energy minimizers. We then consider the effect on an infinitesimal second-order regularization term in the free-energy functional, which fixes the optimal number of defects in the singular configurations.

Swelling dynamics of nematic elastomers. **Peter Palffy-Muhoray** (Kent State University, USA) IC/MT4190/0

Liquid crystal elastomers (LCEs) are exceptionally responsive materials due to the coupling of orientational order and mechanical strain. Changes in orientational order due to thermal, electric, magnetic or chemical excitations can give rise to mechanical deformations. Swelling LCEs with solvents differs from that of isotropic rubbers in that changes in orientational order due to the presence of the solvent contribute significantly to changes in sample shape, giving rise to unusual behavior. We present some results of experiments on swelling monodomain nematic LCE samples with liquid solvents, solvent mixtures and solvent vapors, and discuss the observed excitation and relaxation dynamics. We briefly describe a continuum model, combining features of liquid crystallinity, binary mixtures and elasticity, proposed to describe this behavior. We conclude by considering the potential of the chemical response of LCEs for applications in devices such as chemical sensors, switches and motors. This work was done in collaboration with A. Golemme, T. Toth-Katona, M. Shelley and M Warner.

Effective models for nematic liquid crystals with ferromagnetic inclusions. **Dmitry Golovaty** (The University of Akron, USA), Carme Calderer (University of Minnesota, USA), Antonio DeSimone (SISSA, Trieste, Italy), Alexander Panchenko (Washington State University, USA) IC/MT4193/0

We use the methods of the theory of homogenization to establish the effective models for ferronematics - magnetic suspensions of needle-like particles in a nematic liquid-crystalline matrix. When the volume fraction of slightly prolate spheroidal particles is small, we show that the effective energy functional is essentially the same as the standard Oseen-Frank energy, however the coefficient in front of the term coupling the nematic director to the applied field is much larger than that for the pure nematic. Further, we discuss the influence of the interplay between the elastic/anchoring properties of the nematic, aspect ratio of the particles, and the volume fraction of the particles on characteristics of the effective medium.

Energy minimization and orientability for planar nematic liquid crystals. **Arghir Zarnescu** (University of Oxford, UK), John Ball (University of Oxford, UK) IC/MT5061/015

The Oseen–Frank theory is the model which has been most studied mathematically among those attempting to describe uniaxial nematic liquid crystals. It represents the liquid crystals by means of unit length vector fields describing the local mean orientation of molecules. An apparent deficiency of the Oseen-Frank theory is that is does not recognize the "head-to-tail" symmetry of the physical system. This symmetry is respected by the (constant order parameter) Landau-de Gennes Q-tensor theory, which uses line fields instead of vector fields. A vector field can be reduced to a line field but not necessarily the other way around. There exist line fields that cannot be "oriented" into vector fields, without creating discontinuities. We call such line fields non-orientable. We analyze, in a 2D geometry, the circumstances in which the non-orientable line fields are energetically favoured over the orientable ones. Thus we identify the instances in which the Oseen-Frank theory fails to recognize the correct, physical, energy minimizers.

IC/MP622/131: Inverse problems in electromagnetic scattering.

Organiser: Dietmar Hömberg (Weierstraß-Institut Berlin, Germany)
Co-organiser: Markus Bär (PTB-Berlin, Germany)

Electromagnetic scattering and diffraction in complex geometries are of great relevance to many application in material science and precision measurement. Examples include metamaterials, photonic crystals as well as methods to determine structural properties from indirect measurement e. g. in scatterometry where UV light is scattered at nanostructured functional elements commonly used in microelectronics. In the latter case, the scattering signature is used to reconstruct the geometrical profile of periodic gratings. This process requires the solution of a difficult and computationally intensive inverse problem that involves detailed mathematical analysis as well as efficient numerical procedures. This minisymposium gives an overview of modern application of inverse problems in electromagnetic scattering and addresses issues such as sensitivity analysis, state-of-the art treatment of boundary conditions as well as fast solvers for Maxwellt's equations.

On the direct and inverse problems in fluid–structure interaction. **George Hsiao** (University of Delaware, USA) IC/MT2598/131

This lecture is based on joint work with J. Elschner and A. Rathsfeld of WIAS in Berlin, and it is concerned with the direct and inverse scattering problems in fluid–structure interaction. The scattering problem in the fluid–structure interaction can be simply described as follows: an acoustic wave propagates in the fluid domain of infinite extent where a bounded elastic body is immersed. The direct problem is to determine the scattered pressure and velocity fields in the fluid domain as well as the displacement fields in the elastic body, while the inverse problem is to reconstruct the shape of the elastic scatterer from a knowledge of the far field pattern of the fluid pressure or from the measured scattered fluid pressure field. As is well known, the inverse problems are generally nonlinear and highly ill-posed. For treating inverse problem of this kind, we reformulate the problem as a nonlinear optimization problem including special regularization terms. The precise formulation of the nonlinear objective functional will depend on the approaches of the direct problem. In this lecture we will present various approaches for the direct problem based on the formulations with or without introducing artificial boundaries and their corresponding formulations of the inverse problem. Emphasis will be placed upon the mathematical foundations of the variational formulations of the corresponding problems.

Sensitivity analysis for indirect measurement in scatterometry and the reconstruction of periodic-grating structures. **Andreas Rathsfeld** (Weierstraß-Institut Berlin, Germany), Hermann Gross (PTB-Berlin, Germany) IC/MT1243/131

We discuss numerical algorithms for the determination of periodic surface structures from light diffraction patterns. With decreasing details of lithography masks, increasing demands on metrology techniques arise. Scatterometry as a non-imaging indirect optical method is applied to simple periodic line structures in order to determine parameters like side-wall angles, heights, top and bottom widths and to evaluate the quality of the manufacturing process. The numerical simulation of diffraction is based on the finite element solution of the Helmholtz equation. The inverse problem seeks to reconstruct the grating geometry from measured diffraction patterns. Restricting the class of gratings and the set of measurements, this inverse problem can be reformulated as a non-linear operator equation in Euclidean spaces. The operator maps the grating parameters to special efficiencies of diffracted plane wave modes. We employ a Gauß-Newton type iterative method to solve this operator equation. The reconstruction properties and the convergence of the algorithm, however, is controlled by the local conditioning of the non-linear mapping. To improve reconstruction and convergence, we determine optimal sets of efficiencies optimizing the condition numbers of the corresponding Jacobians. Numerical examples for chrome-glass masks and for inspecting light of wavelength 632.8 nm are presented.

Lithography mask characterization from measured scatterometry data. **Frank Schmidt** (Zuse-Institut Berlin, Germany), Burger Sven (Zuse-Institut Berlin, Germany), Jan Pomplun (Zuse-Institut Berlin, Germany), Lin Zschiedrich (Zuse-Institut Berlin, Germany) IC/MT2682/131

Progress in development of smaller and faster computers is connected to decreasing size of geometrical structures of microchips. Extreme ultraviolet (EUV) lithography is seen as the main candidate for further miniaturization of computer technology. Due to the short wavelength of EUV light (≈ 13 nm) novel reflective EUV masks have to be used in the production process.

EUV masks have geometrical feature sizes of the order of the wavelength of EUV light and are illuminated at oblique incidence. Therefore the quality of pattern profiles of EUV masks becomes very important and has to be controlled.

To simulate light propagation in EUV masks we have to solve Maxwell's equations. For this purpose we have developed an adaptive finite element (FEM) approach on irregular meshes [1]. The usage of irregular triangulations allows us to accurately model the geometry of EUV masks. Special domain decomposition techniques [2] significantly decrease computational time and increase accuracy. These are crucial points for reconstruction of mask parameters from experimental data.

Here we present rigorous simulations of EUV masks with different geometrical mask parameters like side-wall angles, corner roundings, layer heights and widths. We optimize the geometry of simulated EUV masks to fit numerical results to data obtained from experimental scatterometry [3]. The obtained geometrical parameters from this indirect metrology technique are compared to direct quantitative microscopy of EUV mask patterns and show good agreement.

Stochastic characterization of non-stationary over-moded fields. **Luk Arnaut** (National Physical Laboratory, UK) IC/MT2205/131

We investigate the effect of rapid variations of cavity boundaries on the dynamic and stochastic properties of a nonstationary electromagnetic field inside a reverberant enclosure. This case constitutes a generalization of an idealized statistically incoherent, homogeneous, isotropic, quasi-static, random vector field, which is retrieved as a special case. A theoretical model is constructed to show how the field can be characterized as a generalized wave diffusion process. The Langevin–Ito and Fokker–Planck equations, distributions and statistics for the instantaneous field, its magnitude and energy density are derived and solved analytically. The results have applications, in particular, for the characterization of multipath propagation of electromagnetic waves in complex and dynamic environments exhibiting time-varying multiple scattering.

IC/MP250/131: Nonlinear dynamics in lasers.

Organiser: Nathan Kutz (University of Washington, USA)

Mode-locked lasers are one of the most successful commercial devices which are based fundamentally on nonlinear optics. Commercially available pulsed mode-locked lasers are compact, cheap, reliable and robust and have a wide range of applications from optical communications to medical devices. Thus considerable interest and research in the past decade has focused on the use of Erbium-doped fibers in actively and passively mode-locked fiber lasers operating in both the normal and anomalous dispersion regimes. Many mode-locking schemes have been successfully demonstrated. These include active mode-locking with an acousto-optic modulator, passive mode-locking via nonlinear interferometry in the figure eight laser, polarization rotation in the ring laser, and a linear cavity configuration which employs a semiconductor structure for fast saturable absorption. A generic feature of each mode-locked laser is the intensity-dependent loss which is achieved by the mode-locking mechanism. The additional loss imparted upon low-intensity parts of the pulse, whether it

be dispersive radiation or the wings of a pulse, gives the necessary pulse shaping required to achieve stable mode-locking operation. These compact sources of optical pulses near wavelengths of 1.55 microns are key enabling technologies for high speed fiber optic communication systems and interconnection networks.

Accurate modeling of these technologically promising mode-locked fiber lasers is essential to their utilization in practical systems. Many models have been developed which attempt to address various aspects of the mode-locking dynamics ranging from the energy equilibration in the cavity to the polarization dynamics of the pulse and the pulse-to-pulse interactions in a harmonic mode-locking configuration. Each model has merit in describing a certain aspect of the laser dynamics, and it is difficult to develop a single model which encompasses all aspects of the mode-locking dynamics. In this mini-symposia, a variety of mathematical models are presented which address the variety of phenomena observed in laser systems. Special attention is given to the role of nonlinearity in determining the fundamental dynamical behavior in the laser cavity which includes its stability, bifurcation structure, and onset of chaos.

Delay-coupled laser systems: scaling laws and resonances. **Thomas Carr** (Southern Methodist University, USA) IC/MT3562/131

We consider a model for two lasers that are mutually coupled optoelectronically by modulating the pump of one laser with the intensity deviations of the other. Signal propagation time in the optoelectronic loop causes a significant delay leading to the onset of oscillatory output. Multiscale perturbation methods are used to describe the amplitude and period of oscillations as a function of the coupling strength and delay time. Because we allow for independent control of the individual coupling constants, for certain parameter values there is an atypical amplitude-resonance phenomena. Our theoretical results are consistent with recent experimental observations when the inclusion of a low-pass filter in the coupling loop is taken into account.

Mode-locking via nonlinear mode-coupling: global attractors. **Joshua Proctor** (Princeton University, USA) IC/MT4712/131

A detailed analysis of mode-locking is presented in which the nonlinear mode-coupling behavior in a waveguide array, dual-core fiber, and/or fiber array is used to achieve stable and robust passive mode-locking. By using the discrete, nearest-neighbor spatial coupling of these nonlinear mode-coupling devices, low-intensity light can be transferred to the neighboring waveguides and ejected (attenuated) from the laser cavity. In contrast, higher intensity light is self-focused in the launch waveguide and remains largely unaffected. This nonlinear effect, which is a discrete Kerr lens effect, leads to the temporal intensity discrimination required in the laser cavity for mode-locking. Numerical studies of this pulse shaping mechanism show that using current waveguide arrays, fiber-arrays, or dual-core fibers in conjunction with standard optical fiber technology, stable and robust mode-locked soliton-like pulses which act as global attractors are produced.

Multi-frequecy mode-locked lasers. **Edward Farnum** (Kean University, USA) IC/MT4707/131

A new theoretical model is constructed which describes the operation of multi-frequency, pulsed mode-locked laser cavities. The model, which is a combination of multi channel interactions in the canonical master mode-locking model subject to three different gain models which account for both self- and cross-saturation effects, results in mode-locking dynamics which qualitatively describe the observed experimental dual-frequency laser operation. Specifically, the combination of self- and cross-saturation in the gain allows for mode-locking at two frequencies simultaneously, which can be of significantly different energies and pulsewidths. The model gives a framework for understanding the operation and stability of the increasingly important and timely technology of dual- and multi-frequency mode-locked laser cavities.

Dissipative solitons and their interactions. **Nail Akhmediev** (Australian National University) IC/MT3859/131

Coupled soliton pairs in nonlinear dissipative systems can exist in various forms. They can be stationary, or they can pulsate periodically, quasi-periodically or chaotically, as is the case for single solitons. Each type is stable in the sense that a given bound state exists in the same form indefinitely. Single solitons can be perfectly stable for a given set of parameters. However, this does not mean that a bound state formed from them is either stationary or stable. Moreover, their relations can be highly complicated. Such is the life of dissipative solitons.

IC/MP293/132: Mathematical and numerical modeling of quantum transport in nano-structures.

Organiser: Florian Méhats (Université de Rennes 1, France)
Co-organiser: Pierre Degond (Université Paul Sabatier Toulouse III, France)

Improving information and communication technologies relies among others on the design of ultra high-speed and low-consumption electronic devices. This goal requires the reduction of device sizes up to the nanometer scale or even the atomic one. At such scales, quantum interference, tunneling and confinement play an important role and have an extremely high impact on device operation. They can even represent, like in resonant tunneling diodes, the major effects governing the electronic transport. The aim of the minisymposium is to provide an overview of recent developments concerning the mathematical and numerical modeling of quantum transport in nanostructures. The topics will emphasize industrial challenges in the area, the physical important effects and the mathematical modeling and simulation issues related to them, and we will focus on the interplay between physical, engineering and mathematical aspects. Quantum transport in nanostructures can be modeled through a variety of models adapted to different physical situations. At the microscopic level, the Schrödinger equation (or its reformulation using the Green's functions method) can be employed in order to describe ballistic regimes. When the transport is more collisional, a solution consists in using the phase-space counterpart of the Schrödinger equation, the Wigner equation, and taking into account collision effects through Boltzmann type kernels. Such systems are often treated with Monte-Carlo methods. However, these models may be computationnally expensive and a recent area of research consists in the derivation of quantum hydrodynamical systems, in order to describe the system at a macroscopic scale. This minisymposium will propose four talks covering several levels of modeling, from the microscopic to the macroscopic level of description.

Quantum corrected drift-diffusion models: solution fixed-point map and finite-element approximation. **Riccardo Sacco** (Politecnico di Milano, Italy), Joseph Jerome (Northwestern University, USA), Carlo de Falco (Bergische Universitaet Wuppertal, Fachbereich C -, Germany) IC/MT1084/132

In this lecture, we deal with the analysis of the functional iteration proposed in[2] for the decoupled solution of the Quantum Drift-Diffusion (QDD) model. The functional iteration is denoted Generalized Gummel Map, because it is a consistent generalization to the quantum-corrected setting of Gummel's iterative procedure, widely used in contemporary semiconductor simulation based on the DD transport model. The ideas developed in this lecture try to combine the main results of the existence analysis carried out in[1] for the QDD model, with the corresponding analysis of the solution map carried out in[3] in the case of the DD model. It is expected that, with some modifications, the proposed theoretical framework can be extended to deal with other quantum-corrected models, as considered in[2].

Quantum dynamics of ultrafast photoinduced processes in organic semiconductor systems. **Irene Burghardt** (École Normale Supérieure de Paris, France) IC/MT3147/132

The photophysics of π-conjugated organic semiconductor systems is a key ingredient in the technological development of optoelectronic devices. Due to their spatially extended structure, these systems exhibit both the molecular characteristics of their components and the collective electronic excitations (exciton states) characteristic of lattice structures. The coupling between electronic and nuclear motions results in the localization ("self-trapping") of exciton states, along with the coherent nuclear dynamics and vibronic coupling phenomena known from molecular systems. Of particular interest are ultrafast exciton dissociation processes at polymer heterojunctions, comprising two materials with an offset between the constituent valence and conduction bands [1]. For these systems, the non-adiabatic coupling between the initially excited exciton state and a localized charge transfer state plays a key role. As we have recently shown, the subpicosecond scale dynamics of exciton dissociation is indeed essentially of non-adiabatic nature [2,3]. In this presentation, we report on quantum-dynamical simulations of this process using efficient multiconfigurational techniques [2]. We further provide a perspective on the combined description of exciton creation, migration, and localization phenomena in conjunction with quantum non-adiabatic transitions.

Towards high-fidelity large-scale atomistic simulations of emerging materials and electronic devices. **Eric Polizzi** (University of Massachusetts, USA) IC/MT3225/132

In nanoscience research, numerical simulations are vital in focusing experimental investigation for the exploration of new classes of high speed, and high functionality devices. Characterization of nanoscale emerging devices needs to be addressed via reliable, robust and accurate quantum simulations. As a result, comprehensive and realistic electronic structure and electron transport simulations need to account for: (i) information of the material at the atomistic level, (ii) multiscale aspects of electron transport modeling and electrostatics effects, (iii) high-fidelity treatment of the contact regions, and (iv) efficient methodology for dissipative scattering. The quest for ever higher levels of detail and realism in these simulations presents formidable modeling and computational challenges. These nanoelectronics simulations are expected, however, to benefit from the development of specific advanced mathematical techniques and high-performance parallel algorithms to enhance our ability to achieve high-fidelity simulations of materials and transport problems. Here, we propose to investigate novel simulation strategies which aim to go beyond qualitative predictions by proposing quantitative simulations from the atomistic scale to the transistor macroscale.

Quantum Monte-Carlo methods based on a multi-scale approach. **Christian Ringhofer** (Arizona State University, USA) IC/MT3027/132

Quantum mechanical transport phenomena are included into semi-classical Monte Carlo methods for electron gases in a multi - scale framework. The small scale transport picture is based on a general framework to derive macroscopic transport equations for a small set of observables based on maximum entropy closures.

Numerical modelling of flow plasma interactions. **Guillaume Dufour** (ONERA, France), Francois Rogier (ONERA, France) IC/CT1116/013

This paper deals with the numerical modeling of plasma flow interactions at atmospheric pressure and their application to aeronautics. A two-dimensional air plasma modeling including complex air kinetic and flow motion, coupled with the evolution of the generated electrical field, is proposed to describe the plasma creation. The net force exerted by the plasma on the flow is then computed and introduced in a Navier-Stokes solver in order to evaluate its influence on the air flow. The presented model is able to compute pin plate coronas discharges as well as wire to wire ones so that a wide panel of experimental setups is covered. The cornerstone of plasma discharges simulation is the ability to deal with multiscale physical phenomena (the kinetic dynamic is much steeper than the transport of the ions, for example). The objective is then to avoid the limitation imposed by the steepest phenomenon and to reduce the computational time (and cost). In this paper, some numerical methods to overcome this kind of difficulties are presented and the opportunity to use surrogate models is discussed. Finally, numerical simulations are performed for a corona wire to wire discharge and the numerical results obtained are compared with LEA experimental ones, thus emphasizing the ability of the model to predict the correct behaviour of the discharge.

Model reduction of nonlinear systems. **Marissa Condon** (Dublin City University, Ireland) IC/CT399/133

As the accuracy and complexity of the mathematical models that describe dynamical systems grows, the consequence unfortunately is a result in increased computation time and use of computer memory resources. However, in many engineering applications, for example, in controller design for aeronautics or for testing the functionality of an initial RF system design, only the essential behaviour of a system is required. Furthermore repeated iterations are required to identify and select a suitable design. Hence, there is a need to formalise techniques for the accurate formation of reduced-order models to enable rapid repetitive or iterative simulation. While numerous effective techniques exist for linear model reduction, the procedure for nonlinear model reduction is far more complex. With nonlinear predictive control methods or with nonlinear problems associated with analog circuitry or micromachined devices, however nonlinear model reduction has become of paramount importance. In this talk, we will give an overview of the significant procedures for nonlinear model reduction employed at present. In particular, we will look at the general merits and demerits of methods based on balanced truncation and methods based on Krylov approaches. Specifically, we will explore empirical balanced truncation and the use of algebraic gramians for the former method. We will look at projection methods or Krylov approaches in relation to polynomial expansions and bilinear approximations. We will then focus on the perturbative representation of the nonlinear system. We will apply a novel model reduction technique to this representation and explore its use in conjunction with other methods. We will consider a standard test case for comparing the various methods. The efficacy of the novel method will be highlighted.

New finite elements for large-scale simulation of optical waves. **Britta Heubeck** (Universität Erlangen–Nürnberg, Germany), Christoph Pflaum (Universität Erlangen–Nürnberg, Germany), Gunther Steinle (Infineon Technologies AG, Germany) IC/CT4334/131

We present a new technique for the time-dependent simulation of the optical wave and the carrier density in Distributed Feedback (DFB) lasers. The time-dynamic behaviour is simulated by rate equations. These rate equations consist of three coupled partial differential equations: While the optical wave is described by the time-dependent Helmholtz equation, the carrier density is specified by the drift-diffusion equation. This is a pair of coupled partial differential equations characterizing the carrier density in the active zone and within the barriers. Our goal is to solve these rate equations for DFB lasers. As such lasers consist of a long resonator compared to the wavelength of laser light, problems arise when solving this system numerically. Standard finite element methods cannot be applied, as for resolving the wave appropriately, a huge amount of grid points is needed. Furthermore, the Beam Propagation Method is not suitable, as by this method it is difficult to simulate internal reflections.

We propose a new finite element method for solving the two-dimensional Helmholtz resonator equation on long geometries. This method is based on newly developed Trigonometric Finite Wave Elements (TFWE) constructed by linear elements and trigonometric functions. We compare this so-called TFWE Method to common techniques like the Transfer Matrix Method and present numerical results that demonstrate the superiority of our method. Furthermore, our approach requires less grid points compared to standard finite elements since the TFWE lead to a more accurate approximation of the optical wave. Thus, we get a smaller linear system of equations which eases the solving process. Another advantage is that the TFWE simplify the modelling of boundary conditions (bc), in particular of the absorbing bc. The TFWE Method can also be applied to two-dimensional configurations when other methods fail. Finally, typical experimental lasing effects, e.g. spatial hole burning, can be simulated.

Performance of various block preconditioners for FEM modeling of semiconductor devices. **Paul Lin** (Sandia National Laboratories, USA), John Shadid (Sandia National Laboratories, USA), Robert Hoekstra (Sandia National Laboratories, USA), Gary Hennigan (Sandia National Laboratories, USA) IC/CT2522/132

Approximate block factorization preconditioners are applied to the drift-diffusion equations for modeling semiconductor devices. The block factorization essentially produces a "physics-based" preconditioner for the drift-diffusion system. The system is comprised of a nearly singularly perturbed elliptic constraint for the electric potential, and two parabolic convection-diffusion-reaction equations for the electron and hole concentrations. The resulting scalar subsystems are solved by various iterative methods including AMG-type techniques. We demonstrate these techniques by employing a stabilized finite element discretization of the drift-diffusion equations on structured and unstructured meshes. The nonlinear coupled system is solved with a parallel preconditioned Newton-Krylov method. Preliminary results will be presented demonstrating the performance of the approximate block factorization preconditioners compared with one-level and multilevel domain decomposition preconditioners. This work was partially funded by the DOE NNSA's ASC Program and the DOE Office of Science AMR Program, and was carried out at Sandia National Laboratories operated for the U.S. Department of Energy under contract no. DE-ACO4-94AL85000

Sorting of microparticles in periodic and random potentials. **James Gleeson** (University College Cork, Ireland) IC/CT1938/010

There has been a recent revolution in the ability to manipulate micrometer-sized objects on surfaces patterned by traps or obstacles of controllable configurations and shapes. One application of this technology is to separate particles driven across such a surface by an external force according to some particle characteristic such as size or index of refraction. The surface features cause the trajectories of particles driven across the surface to deviate from the direction of the force by an amount that depends on the particular characteristic, thus leading to sorting. While models of this behavior have provided a good understanding of these observations, the solutions have so far been primarily numerical. In this work we provide analytic predictions for the dependence of the angle between the direction of motion and the external force on a number of model parameters for periodic as well as random surfaces. We test these predictions against exact numerical simulations.

A global approach of electromagnetism dedicated to further long-term planning. **Vincent Mazauric** (Schneider Electric, France), Nadia Maïzi (Ecole des Mines de Paris, France) IC/CT3347/131

In order to provide a vision of power electrical engineering for future energy-supply crossroads and sustainable challenges, quasi-static laws of electromagnetism are deduced from experimental evidences, the electric charge conservation and variational principles derived from thermostatistics. While flux-density divergence free is obtained everywhere from the stationary condition on the Gibbs' free energy, the Maxwell-Faraday equation and the Ohm's law with motion are obtained in conductors by assuming a trend for a reversible evolution of the electromagnetic field. In other words, the local laws of electromagnetism may be obtained from an optimization of the global mechanical power exchanged throughout the electrical network. The approach is shown to be: (i) consistent with Finite Element Method ; (ii) coherent with a coarse graining optimization, from scratch to the design scale ; (iii) suitable to consolidate energy processes involved in electromagnetic and electromechanical conversion. Hence, two kinds of devices are identified: (i) those dedicated to power conversion where the highest efficiency should be achieved; and their (ii) couplings involved in transmission lines, distribution busways, cablings and PCBs where the voltage does not drop. In spite of this ideal trend, an actual network undergoes irreversible processes for the length- and time-scales on which it is monitored. Usually, this lack of information is counteracted by the reactive energy for admissible load fluctuations. Hence, for a given level of reliability, the network management results from a compromise between: stock of reactive energy and investment for the monitoring and rush production capabilities. Such an approach should allow to improve the Life Cycle Assessment of the electrical supply-chain and consequently provide a description of power electrical engineering suitable for long-term planning.

A Dirichlet-to-Neumann map approach to photonic-crystal modeling. **Ya Yan Lu** (City University of Hong Kong) IC/CT1022/131

Photonic crystals are engineered material with periodic structures on the scale of a wavelength of the light. Due to the existence of photonic bandgaps (these are intervals of the frequency, such that light corresponding to a frequency in a bandgap cannot penetrate the photonic crystal), they could play a very important role in future integrated optical circuits, a role as semi-conductors in current electric integrated circuits. Mathematical modeling and numerical simulations of photonic crystals are challenging. Existing numerical methods that discretize the whole structure are not very efficient. We develop a special class of methods based on the Dirichlet-to-Neumann maps. The efficiency and accuracy of our methods are illustrated in numerical examples for computing the bandgaps, transmission spectra and waveguide modes of photonic crystals.

Optical solitons with dual power-law nonlinearity. **Anjan Biswas** (Delaware State University, USA) IC/CT1121/131

The multiple scale perturbation analysis is used to study perturbed optical solitons that are governed by nonlinear Schrödinger's equation with dual-power law nonlinearity. The perturbations due to nonlinear damping and saturable amplifiers are considered. This method obtains new results that are not recoverable by the traditional soliton perturbation theory.

Comparison of solution techniques for the linear system arising from the discretisation of time-harmonic scattering problems with $H(\mathrm{curl})$ elements. **Paul Ledger** (Swansea University, UK) IC/CT3737/131

This talk is concerned with approaches for the solution of the linear system of equation which arises when the vector wave equation for time harmonic scattering problems is discretised by $\vec{H}(\mathrm{curl})$ conforming finite elements on three–dimensional unstructured grids. The hp version of the finite element method is employed as it enables singularities to be captured without effecting smooth parts of the solution. In addition, a perfectly matched layer (PML) technique is used to truncate an otherwise infinite domain close to the scatterer.

The coefficient matrix which arises in this case is complex symmetric and indefinite. These properties are less than desirable and make this type of linear equation system notoriously difficult to solve. However, the structure of the coefficient matrix is sparse and contains many non zero entries and so may be stored efficiently. The actual dimension of the matrix depends on the level of refinement required for the problem being solved. One new emerging application is in the use of computational electromagnetics for cancer detection and for these problems the frequencies of interest are measured in microwaves. Using hp finite elements to solve time harmonic scattering problems at these frequencies translate to matrices which can readily be stored on a personal computer.

The computational performance of current direct and iterative solution strategies will be compared for a range of linear systems arising from the discrtisation of different problems. In particular, we shall investigate how well different preconditioners perform when applied to iterative solution algorithms. Possible modifications to the hp discretisation to facilitate easier linear equation solution will also be discussed.

Spectral filtering for ultra-short pulse generation in the normal (defocusing) dispersion regime . **Brandon Bale** (University of Washington, USA) IC/CT4733/010

Recent experiments show that ultra-short pulse generation can be obtained using a spectral filter in the normal dispersion regime of a laser cavity. The ratio of the width of the gain bandwidth to the width of the spectral filter is critical in determining the stability of the generated sinc-like mode-locked pulses. The spectral filtering allows one to obtain peak powers and pulse widths on the order of those achieved in the anomalous regime. We perform an extensive study of numerical and reduced models which characterize the stability and dynamics of the spectral filtering mode-locking process.

IC/PP1100/010: Effect of dynamical cosmological constant in presence of modified Chaplygin gas for accelerating universe.

Presenter: Ujjal Debnath (Bengal Engineering and Science University, India)
Co-author: Writambhara Chakraborty (Kolkata, India)

In this paper we have considered the Universe to be filled with modified gas and the cosmological constant Λ to be time-dependent, with or without the gravitational constant G being time-dependent. We have considered various phenomenological models for Λ; viz., $\Lambda \propto \rho, \Lambda \propto \frac{\dot{a}^2}{a^2}$ and $\Lambda \propto \frac{\ddot{a}}{a}$. Using these models it is possible to show the accelerated expansion of the Universe at the present epoch. Also we have shown the natures of G and Λ over the total age of the Universe. Using the *statefinder* parameters we have shown the diagramamtical representation of the evolution of the Universe starting from radiation era to ΛCDM model.

IC/PP5056/131: Estimating the eddy-current modelling error.

Presenter: Kersten Schmidt (ETH Zürich, Switzerland)
Co-author: Oliver Sterz (Computer Simulation Technology, Germany)
Co-author: Ralf Hiptmair (ETH Zürich, Switzerland)

The eddy-current model is an approximation of the full Maxwell equations. We will give estimates for the modelling error and show how the constants in the estimates are influenced by the geometry of the problem. Additionally, we analyse the asymptotic behaviour of the modelling error when the angular frequency tends to zero. The theoretical results are complemented by numerical examples using high-order finite elements demonstrating that the estimates are sharp.

IC/PP4795/015: Computationally efficient simulation of polymer electrolyte fuel cells and stacks.

Presenter: Jens Eller (Zurich University of Applied Sciences Winterthur„ Switzerland)
Co-author: Markus Roos (Zurich University of Applied Sciences Winterthur„ Switzerland)
Co-author: Guido Sartoris (Zurich University of Applied Sciences Winterthur„ Switzerland)
Co-author: Jürgen Schumacher (Zurich University of Applied Sciences Winterthur„ Switzerland)

A computationally efficient model of a proton exchange membrane (PEM) fuel cell is presented. The approach is used for simulation of PEM single cells and stacks. In the framework of this "2+1D"-approach the anodic and cathodic fields are discretised in two dimensions with our finite element software SESES. The coupling between the anodic and cathodic side is established by a one-dimensional model representing the gas diffusion layer (GDL) and the membrane electrode assembly (MEA).

The nonlinear 1D model of the MEA and the GDLs is created by starting from the symbolic weak form expressions of the coupled transport phenomena. The tangential stiffness matrix of the coupled FEM problem is computed analytically by the computer algebra software Mathematica. As a next step a numerical FEM solution of the 1D model is calculated with Mathematica. Model validation is achieved by comparing the numerical 1D solution to spatially resolved current measurements with a fuel cell that is fed with pure oxygen. Finally, the validated 1D model of the MEA and the GDL is implemented with the programming language C and linked to SESES.

Coupling between the 1D model and the two 2D models in SESES is achieved by using the values of the degrees-of-freedom (DOF) variables of the 2D model as Dirichlet boundary conditions for the 1D model. The 1D model returns amendment for the right hand side of the solved governing equations in 2D computed as the non-zero residual at the 1D boundaries and their numerical derivatives with respect to the 1D Dirichlet boundary values.

This approach is suitable to take the high aspect ratio between the in-plane and the through-plane dimensions of fuel cells into account. The number of DOF variables is significantly reduced in comparison to a full 3D model approach. Further, this modelling approach can also be applied to other fields, e.g. for the description of coupled electro-chemical processes.

14: Computational Sciences, Minisymposia

IC/MP237/014: Problems involving interfaces: from models to computations.

Organiser: Georges-Henri Cottet (Université Grenoble I, France)
Co-organiser: John Strain (University of California, Berkeley, USA)

A number of computational problems in various applications critically involve interfaces. Whether they arise in e.g. mechanical engineering, physics or biomechanics, these problems share some common requirements:

- coupling between different types of physics and therefore different mathematical and numerical models, and
- capturing accurately a wide range of scales, in particular close to the interface.

Interfaces are often related to stability questions and numerical models must be able to distinguish between physical and numerical stability. Problems involving interfaces also require a choice between explicit interface tracking and implicit interface capturing.

This minisymposium will focus on several challenging applied problems where interfaces play a crucial role, in fluid dynamics, solid physics and fluid-structure interactions. The speakers will present state-of-the-art techniques, from model-oriented, mathematical and numerical points of view.

Pattern formation at the nano-scale in molecular beam epitaxy. **Olivier Pierre-Louis** (Université Joseph Fourier Grenoble, France) IC/MT2144/014

Molecular Beam Epitaxy is a major tool for the growth of atomically flat films. But a number of complex patterns are also observed during this type of growth. We here show how different techniques are used in order to determine the morphological evolution of the surface. We will analyze in more details the so-called phase field models. We will show how these models can either be (i) physical models, analogous to the phenomenological Ginzburg-Landau models; or (ii) tools for numerical simulations, which share similarities with level set models. Depending on the use which is made of the phase field, we will see how different constraints emerge on the formulation of the model.

Crystalline evolutions: a mathematical approach. **Matteo Novaga** (Università di Pisa, Italy) IC/MT768/014

I will discuss some aspects of motion by mean curvature of hypersurfaces in presence of nonsmooth anisotropies, including the so-called crystalline evolutions. I will give a survey of known results, and present some open problems.

Generalized Navier boundary condition for the numerical simulation of moving contact lines in two-fluid flows. **Jean-Frédéric Gerbeau** (INRIA Rocquencourt, France), Tony Lelièvre (École Nationale des Ponts et Chaussées, France) IC/MT810/014

We are interested in the numerical simulation of two incompressible viscous fluids separated by a free interface. We use an Arbitrary Lagrange Euler (ALE) formulation of the problem.

The purpose of the talk is to address various numerical issues, in particular some stability and conservation properties. The role of the Geometric Conservation Law (GCL) will be discussed. We will introduce a notion of *Surface Conservation Law* which may be helpful to analyse the numerical scheme when the surface tension is taken into account.

A difficult problem in the modelling of two-fluid flows in a bounded domain concerns the displacement of the contact line, namely the points which are at the intersection of the boundary of the domain and the interface separating the two fluids. We will show that variational formulations are well-suited to the *Generalized Navier Boundary Conditions* introduced by Qian, Wang and Sheng. Owing to these boundary conditions, it is possible to circumvent the incompatibility between the classical no-slip boundary condition and the fact that the contact line of the interface on the wall is actually moving. We will present numerical experiments on two-fluid flows in narrow channels and we will compare these results with molecular dynamics simulations from the literature.

Fast and accurate computation of layer heat potentials. **Jing Rebecca Li** (INRIA Rocquencourt, France), Leslie Greengard (Courant Institute, NYU, USA) IC/MT4982/014

We evaluate the single and double layer heat potentials in two dimensions on and off a moving boundary. The algorithm uses a high order quadrature in time which takes into account the integrable singularity at the endpoint as well as the smoothness of the integrand a short distance away. If a time quadrature point τ is close to the singularity, the spatial integral at τ is computed locally, using interpolated values. Otherwise it is computed using the Fast Gauss Transform. This algorithm can be used to compute the local part of layer potentials, in conjunction with the Fourier domain computation of the smooth part, while ensuring that the errors made in the local and the smooth parts are of a comparable magnitude. It can also be used adaptively to compute the full layer potential to a prescribed accuracy.

IC/MP237/014: Problems involving interfaces: from models to computations. #2

Organiser: Georges-Henri Cottet (Université Grenoble I, France)
Co-organiser: John Strain (University of California, Berkeley, USA)

(For abstract, see session #1 above.)

Bodies interacting with and through fluids. **Michael Shelley** (Courant Institute, NYU, USA) IC/MT2966/014

The interaction of flowing fluids with free bodies (sometimes compliant, sometimes active, sometimes multiple) constitutes a class of beautiful dynamic boundary problems that are central to biology and engineering. Examples range from how organisms locomote in fluids (which depends strongly on scale) to how non-Newtonian stresses develop in complex liquids (strongly dependent on the nature of fluidic microstructure). I will discuss several interesting examples, emphasizing how they are formulated mathematically so as to yield models tractable for analysis or simulation, and show how this work has interacted with experimental studies.

New methods in fluid-structure coupling with application to biomechanics. **Emmanuel Maitre** (Université Grenoble I, France), Georges-Henri Cottet (Université Grenoble I, France), Thomas Milcent (Université Grenoble I, France) IC/MT3499/014

An eulerian approach is presented for generic fluid-structure coupling of an elastic body with an incompressible fluid. We consider the coupling as a multiphysics problem where fluid-solid interfaces are captured by a level-set method. The main features of the method are its simplicity, and its natural control of mass and energy. We are indeed able to prove an energy equation which ensures in particular that the regularization of the force does not involve any energy dissipation. Applications to membranes oscillation and cardiomyocyte contraction are presented.

Locally-corrected semi-Lagrangian methods for Stokes flow with moving elastic interfaces. **J Thomas Beale** (Duke University, USA) IC/MT2542/014

We describe a numerical method developed in work with J. Strain for computing time-dependent viscous flow with a moving interface which responds elastically to stretching. For the motion of the interface we use Strain's semi-Lagrangian contouring method. The Stokes velocity is computed as a potential integral in a periodic box using Ewald summation, with the smooth part found as a Fourier series and the remaining part treated as a local correction.

Fast solvers for fluid membranes in 2D. **George Biros** (University of Pennsylvania, USA) IC/MT2812/014

Fluid membranes are area-preserving interfaces that resist inbending. They are common in biophysics as they model cell membranes, vesicles, and viral particles. In this talk we will discuss fast solvers for the time evolution of fluid membranes immersed in a Stokesian fluid. In particular we will discuss time-stepping, stability restrictions, and stiffness. The overall formulation is based on a spectral adaptive discretization and a boundary integral formulation for the Stokes operator.

IC/MP70/014: Automatic differentiation: applications and tools.

Organiser: Uwe Naumann (RWTH Aachen, Germany)
Co-organiser: Paul Hovland (Argonne National Laboratory, USA)

The ability to compute derivatives of outputs of numerical simulation programs with respect to a potentially very large number of parameters plays an increasingly important role in the attempt to make the transition from mere simulation of real-world processes to the highly desirable optimization of the numerical models. Adjoint models in particular are crucial prerequisites for the successful solution of the arising large-scale nonlinear optimization problems. Classical numerical differentiation may lack the desired accuracy. More importantly, the computational complexity of finite differences makes it simply inapplicable to large-scale problems. Hence, many man years have been invested into developing and maintaining such models manually.

Software tools for automatic differentiation (AD) are being developed with the aim to make the computation of derivatives robust, efficient, and potentially fully automatic. They have proved extremely useful in a wide range of applications. The state of the art in both the application of AD technology and the development of new AD tools is described in Bücker, Corliss, Hovland, Naumann, Norris: *Automatic Differentiation: Applications, Theory and Implementations*, LNCSE 50, Springer, 2006. Links to research groups and tool developers as well as descriptions of applications and an extensive bibliography on the subject can be found on the AD-community's Internet site www.autodiff.org.

This minisymposium consists of two sessions. Following a gentle introduction to the principles behind AD three presentations of applications set the stage for four talks about modern AD tools for Fortran and C/C++. The target audience comprises everybody who requires derivatives of mathematical models implemented as numerical simulation programs written in C/C++ or Fortran. Our aim is to make AD technology accessible to a wider range of potential users.

The OpenAD project: ADIC 2.0 and OpenAD/F. **Paul Hovland** (Argonne National Laboratory, USA), Boyana Norris (Argonne National Laboratory, USA), Jean Utke (Argonne National Laboratory, USA) IC/MT2535/014

We describe the OpenAD project, which includes two tools, ADIC 2.0 and OpenAD/F, for the automatic differentiation of ANSI C and Fortran 90, respectively. We introduce the tool architecture, which includes several shared components, including the xaif XML schema for representing the mathematically relevant aspects of a computation, the xaifBooster transformation engine, and the OpenAnalysis framework for compiler analyses. We discuss ongoing work on efficient second derivative (Hessian) computations and efficient derivative computations for MPI-parallelized applications. We highlight the use of the tools in several applications.

Adjoint-based quasi-Newton methods. **Andreas Griewank** (Humboldt-Universität zu Berlin, Germany) IC/MT2967/014

The cheap evaluation of Jacobian vector-products facilitated by the reverse mode of automatic differentiation opens up a new avenue of low rank updating. One resulting update formula combines the properties of heredity and least change stability, which can be shown to imply the attainment of the maximal convergence order achievable by secant methods.

Adjoint-enabled NAGWare *Fortran compiler.* **Jan Riehme** (University of Hertfordshire, UK), Uwe Naumann (RWTH Aachen, Germany) IC/MT3136/014

CompAD-II is the successor of a very successful collaboration between the University of Hertfordshire,Hatfield, UK and the Numerical Algorithm Group (NAG), Oxford, UK.

Whereas CompAD-I was focused on the first-time integration of forward mode Automatic Differentiation within an industrial strength compiler, the main goal of CompAD-II is to implement a robust adjoint mode in the NAGWare Fortran 95 compiler.

The user has to compile the top-level routine with the new `-ad` compiler switch. Than the compiler will do all necessary type changes for active variables automatically without further user interaction.

We will use a hybrid approach combining source transformation and overloading techniques that allows us a stepwise transition from an almost overloading based first prototype towards source transformation tool by replacing overloaded operators step by step with direct modifications on the compiler internal representation at compile time.

We will present the results of the first 10 months of the CompAD-II project and will give an outlook to the remaining duration of project (14 month).

ADiCape: AD for portable process systems models. **Monika Petera** (RWTH Aachen, Germany) IC/MT1156/014

CapeML is a platform independent XML-based language for describing models in process systems engineering. ADiCape is an XSLT-based differentiation tool for the automatic differentiation of model equations expressed in CapeML. The ADiCape tool currently employs the forward mode of AD in the computation of first and second order derivatives, including an interface for sparsity aware compression of Jacobian and Hessian matrices. Here we report on the design of ADiCape, including recent optimizations to account for the equation-based nature of CapeML "programs", as well as applications in large-scale process control engineering.

IC/MP70/014: Automatic differentiation: applications and tools. #2

Organiser: Uwe Naumann (RWTH Aachen, Germany)
Co-organiser: Paul Hovland (Argonne National Laboratory, USA)

(For abstract, see session #1 above.)

Introduction to automatic differentiation. **Uwe Naumann** (RWTH Aachen, Germany) IC/MT543/014

This introduction to Automatic Differentiation (AD) is to set the stage for the following talks. We will review the forward and reverse modes as well as point out issues in tool development and derivative code optimization. Our objective is that everybody in the audience will be familiar with the concepts of tangent-linear code (generated by forward mode AD), adjoint code (generated by reverse mode AD), and approaches to AD tool development based on source transformation or overloading.

Automatic differentiation for C and C++ codes: ADOL-C. **Andrea Walther** (TU Dresden, Germany) IC/MT1037/014

The AD-package ADOL-C uses operator-overloading for the Automatic Differentiation of C and C++ codes: Each double variable on the path from the independent variables to the dependents is replaced by a variable of the new type adouble introduced by ADOL-C. During the evaluation of the function to be differentiated the usage of the new data-type adouble causes the generation of an internal function representation called *tape*. Subsequently this internal representation is used to compute the desired derivative objects.

Several drivers provided by ADOL-C allow a very flexible choice of the mode and order of differentiation to be performed, including the computation of higher derivative tensors and sparsity structures. Furthermore, the Taylor coefficient vectors and their Jacobians with respect to the current state vector of solution curves defined by ordinary differential equations can be calculated. Note that ADOL-C can handle codes based on classes, templates and other C++-features. The derivative calculations involve a possibly substantial but always predictable amount of data that are accessed strictly sequentially. The much smaller randomly accessed memory can be precalculated using information on the tape.

The tape can be used to calculate derivatives for other arguments as long as the control flow of the program stays the same. Hence, the ideal situation is to generate the tapes once and reuse them for all derivative calculations. Then the effort of logging the whole function evaluation should be negligible.

The talk sketches the overloading strategy in more detail including the taping mechanism of the internal representation. Furthermore, recent developments, including checkpointing facilities, are presented. Finally, some examples illustrate applications of ADOL-C.

TAPENADE: a tool for automatic differentiation of programs. **Benjamin Dauvergne** (INRIA Rocquencourt, France) IC/MT2314/014

We present TAPENADE, a tool for Automatic Differentiation (AD) by program transformation. Given a Fortran77 or Fortran95 program that evaluates a function, TAPENADE can produce tangent programs that compute directional derivatives, and adjoint programs that compute gradients. Documentation of TAPENADE, together with access to the tool itself, are available on our web site http://www-sop.inria.fr/tropics. TAPENADE development started in 1999, and it has now a wide range of applications on industrial codes. We will show how the principles of AD are reflected in TAPENADE's differentiation model, and illustrate internal algorithms and results on some code examples.

Gradients are probably the most promising derivatives, as they are essential in optimization. Therefore, they receive a particular attention and development effort in TAPENADE. We would like to emphasize the static data-flow analysis techniques that make AD-generated adjoints perform comparably to good hand-written tangents or adjoints, at a cheaper development cost. In particular, the proeminent features of the tool are activity analysis, TBR analysis, and dead adjoint code elimination, all of them running interprocedurally. The reverse mode of TAPENADE is based on the so-called "Store-All" approach, combined with Checkpointing. We will show how TAPENADE can let the end-user refine from the default automatic checkpointing choices, and we will discuss some experimental heuristics that can refine these choices mechanically.

We shall show some successful applications of TAPENADE to large scale applications: gradient-based shape optimization in CFD, and variational data-assimilation in Earth sciences. We will conclude with a discussion on present limitations of the AD model and a description of future tool developments.

AD in meteorology. **Peter Korn** (Max-Planck-Institut für Meteorologie, Germany) IC/MT2758/014

The first part of this talk gives an overview of the applications of Automatic Differentiation (AD) in modeling the atmosphere and ocean circulation. The emphasis of the overview is placed on variational data assimilation methods. The mathematical basis for these methods is provided by the adjoint method of optimal control theory. The second part of the talk focuses on the challenge that is imposed by the presence of turbulence on AD based methods of adjoint flow control. We show results that indicate that turbulence closure via Lagrangian averaging provides a suitable framework for the control of three-dimensional turbulent flow.

IC/MP646/010: Lattice-Bolzmann methods for multiphase fluid and particle suspension flows.

Organiser: Omar al-Khayat (Simula Research Laboratory, Norway)
Co-organiser: Hans Petter Langtangen (Simula Research Laboratory, Norway)

Over the recent years, Lattice Boltzmann methods (LBM) have proven to be a viable alternative to traditional CFD in fluid flow simulations. Originating from Physics, LBMs have been successfully used in many cross-disciplinary fields of applied science. In many cases, the LBM approach has allowed relatively easy ways of simulating processes that are difficult or impossible to model by traditional CFD methods. In this minisymposium we will present various aspects of the LBM approach, including implementation, optimization, and its applicability for geoscientific problems, such as multiphase flow and depositional processes.

Simulations of dynamic properties of suspensions. **Dewei Qi** (Western Michigan University, USA) IC/MT3581/010

A review of spherical, non-spherical, rigid and flexible particle suspensions by using lattice Boltzmann simulations will be given. In particular, the method for flexible fiber suspensions is developed. The applications of the flexible fiber suspension in shearing, sedimenting and pressure driven flows will be presented. Effects of fiber flexibility on micro structure and rheological properties are studied and reported.

Lattice-Boltzmann model for dissolution phenomena. **Frederik Verhaeghe** (Katholieke Universiteit Leuven, Belgium) IC/MT1670/010

In this talk we present a lattice Boltzmann model for complex dissolution phenomena in three dimensions. We study the dissolution behaviour of a spherical particles in a cubic enclosure with and without double-diffusive natural convection. The results are compared with dissolution experiments conducted with a confocal scanning laser microscope with heat stage.

Hybrid parallelization techniques for lattice-Boltzmann free surface flows. **Ulrich Rüde** (Universität Erlangen–Nürnberg, Germany) IC/MT5050/010

This talk will present an algorithm to perform adaptive free surface simulations with the lattice Boltzmann method (LBM) on machines with shared and distributed memory architectures. Performance results for different test cases and architectures will be given. The algorithm for parallelization yields a high performance, and can be combined with the adaptive LBM simulations. Moreover, the effects of the adaptive simulation on the parallel performance will be evaluated.

This is a joint work with Nils Thuerey.

IC/MP285/010: Mathematical algorithms, frameworks, and scientific applications on large-scale parallel machines.

Organiser: Xiaoye Li (Lawrence Berkeley National Laboratory, USA)
Co-organiser: Osni Marques (Lawrence Berkeley National Laboratory, USA)

The development of high performance simulation codes is a demanding process, due to the complexity of the phenomena to be simulated as well as the growing sophistication of computer architectures. The success of such efforts requires close collaboration of domain scientists, applied mathematicians and computer scientists in the process of developing models, implementing numerical algorithms, and performing code optimization to achieve optimal use of the computational resources.

The purpose of this minisymposium is twofold. Firstly, it focuses on a set of cutting edge mathematical tools, portable software libraries, and friendly frameworks being developed and used to tackle scientific computing applications. The availability of such advanced tools has enabled more complex physical phenomena to be addressed and as a result contributed to the growth of the computational sciences community. Secondly, the minisymposium includes presentations on a set of challenging applications, such as electronic structure calculations, modeling of incompressible flow, and electromagnetic problems. These applications require significant computing resources but have also fostered the development of novel mathematical tools and revealed new opportunities in algorithm research.

Evaluation of the AMLS method for sparse eigenvalue problems. **Xiaoye Li** (Lawrence Berkeley National Laboratory, USA) IC/MT1149/010

We describe an efficient implementation and present a performance study of an algebraic multilevel sub-structuring (AMLS) method for sparse eigenvalue problems. We assess the time and memory requirements associated with the key steps of the algorithm, and compare it with the shift-and-invert Lanczos algorithm in computational cost. Our eigenvalue problems come from two very different application areas: the accelerator cavity design and the normal mode vibrational analysis of the polyethylene particles. We show that the AMLS method, when implemented carefully, is very competitive with the traditional method in broad application areas, especially when large numbers of eigenvalues are sought.

This is joint work with Weiguo Gao, Chao Yang, and Zhaojun Bai.

The use of hybrid techniques at CERFACS for the solution of large-scale problems on parallel machines. **Iain Duff** (Rutherford Laboratory & CERFACS, UK), Serge Gratton (CERFACS, France), Xavier Vasseur (CERFACS, France) IC/MT2087/010

In this talk we will review some recent developments on the combined use of direct and iterative methods for solving very large linear systems of equations, such as those arising in the solution of large 3D PDE's.

We first examine the size of the largest problems that can be solved by current direct methods in 2007. We then discuss some of the algorithmic developments undertaken by the developers of these methods to solve larger problems. Current areas of investigation include the use of out-of-core techniques, and the parallelization of the symbolic factorization phase. An obvious alternative to direct methods are iterative methods. However, it is well known that they encounter difficulties for large ill-conditioned or ill-scaled problems. In these cases, iterative methods may exhibit poor convergence if not adequately preconditioned. We review how these two types of methods can be combined to solve very large and sparse linear systems. A successful combination that will be specially considered is the use of a Krylov method preconditioned by some technique involving a direct method.

In this talk, we will focus on two main applications. For the first, an approximate factorisation of the matrix is performed using static pivoting strategies. We show how the solution of symmetric indefinite problems can be refined by a Krylov method to yield a backward stable solution of the original problem. Secondly, we consider the numerical simulation of seismic wave propagation in three dimensions. This requires a robust and fast solution of the Helmholtz equation. A multigrid method used as a preconditioner for a Krylov method is investigated. We will examine the effect of incorporating the direct solver inside the multigrid framework and its impact on the preconditioner and illustrate the performance of this approach on our parallel machines at CERFACS.

Adaptive numerical components for PDE-based simulations. **Boyana Norris** (Argonne National Laboratory, USA), Lois McInnes (Argonne National Laboratory, USA), Sanjukta Bhowmick (Argonne National Lab. & Columbia Univ., USA), Dinesh Kaushik (Argonne National Laboratory, USA) IC/MT2567/010

Numerical simulations based on nonlinear PDE solution using Newton-based methods require the solution of large, sparse linear systems of equations at each nonlinear iteration. Typically in large-scale parallel simulations such linear systems are solved using iterative preconditioned Krylov methods. In many cases, especially in time-dependent problems, the linear system characteristics can change throughout the stimulation, potentially leading to varying times for solving the linear systems in different nonlinear iterations. We present an approach to characterizing the nonlinear and linear system solution and using the resulting application performance information to dynamically select linear solver methods with the goal of reducing the total time to solution. We discuss the effect of these adaptive heuristics on a number of applications, including fluid dynamics and radiation transport simulation codes. We also present a general component infrastructure for the support of dynamic algorithm selection and adaptation in applications involving the solution of nonlinear PDEs.

EigAdept: an expert eigensolver toolbox. **Osni Marques** (Lawrence Berkeley National Laboratory, USA), Xiaoye Li (Lawrence Berkeley National Laboratory, USA) IC/MT1779/010

The computation of eigenvalues and eigenvectors is an important and often time-consuming phase in a large range of computer simulations. Recent efforts in the development of libraries that implement eigenvalue solvers have provided domain scientists with robust algorithms, without the need for domain scientists to spend much time in programming. Yet, given the variety of numerical algorithms that are available to a practitioner, the choice of the *optimal* algorithm for increasingly sophisticated and larger applications is a daunting task. In this presentation we discuss a methodology and a software toolbox that aims at guiding a practitioner through the maze of various eigenvalue solvers with different configurations, and at determining the more appropriate solver based on the type of the application the properties of the associated matrices.

IC/MP285/010: Mathematical algorithms, frameworks, and scientific applications on large-scale parallel machines. #2

Organiser: Xiaoye Li (Lawrence Berkeley National Laboratory, USA)
Co-organiser: Osni Marques (Lawrence Berkeley National Laboratory, USA)

(For abstract, see session #1 above.)

Implicit methods for low Reynolds-number free-surface flows. **José Cuminato** (Universidade de São Paulo, Brazil) IC/MT788/010

One the most widely used methods in computational fluid dynamics for solving satisfactorily free surface flow problems, governed by the Navier-Stokes equations, is the MAC method [F.H. Harlow and J.E. Welch, Physics of Fluids, 8 (1965) 2182-2189]. Based on the MAC method, many techniques have been developed for solving problems in computational rheology. Generally, these methods use an explicit formulation, as GENSMAC (GENeralized Simplified Marker-And-Cell) method [M.F. Tomé and S. McKee, J. Comput. Phys., 110 (1994) 171-186]. The explicit time discretization introduces the parabolic stability restriction, making, for some applications, the time step very small when the Reynolds number is much smaller than 1. This fact justifies the need for methods with better stability properties like implicit schemes. In this work, we present a stable semi-implicit formulation for the numerical solution of transient, Newtonian and incompressible flows based on splitting the original problem into successive subproblems cheaper to solve. This formulation is known as fractional step or projection method and aim at calculating the velocity and pressure fields separately. The boundary conditions (free surface and rigid) are discretized implicitly to preserve the stability of the semi-implicit method. The numerical results demonstrate that the present technique eliminates the parabolic stability restriction required by the original explicit GENSMAC method, and also found in segregated semi-implicit methods with time-lagged boundary conditions. For low Reynolds number flows, the method is robust and very efficient when compared to the original GENSMAC method.

Parallel performance issues for multiphysics adaptive mesh-refinement algorithms. **John Bell** (Lawrence Berkeley National Laboratory, USA) IC/MT1481/010

Adaptive Mesh Refinement (AMR) is an effective tool for the solution of partial differential equations often requiring far fewer computational resources as compared to equivalently resolved non-adaptive calculations. Hierarchical approaches AMR algorithms, originally developed for gas dynamics, are now used in a number of multiphysics applications. The added algorithmic complexity of AMR algorithms combined with the requirements of multiphysics applications makes parallelization of these types of algorithms a challenging topic. Key issues in developing efficient parallel implementations include load balancing, data distribution, non-numerical metadata manipulations and linear solvers. In this talk, we will discuss each of these issues in the context of several applications drawn from combustion, astrophysics and subsurface flow. For each issue we will characterize the difficulty and describe approaches to improving performance. Finally, we will discuss the impact of these algorithmic improvements on overall scaling behavior.

Derivative-free optimization methods for surface structure determination of nano-systems. **Juan Meza** (Lawrence Berkeley National Laboratory, USA) IC/MT1267/010

Many properties of nanostructures depend on the atomic configuration at the surface. One common technique used for determining this surface structure is based on the low energy electron diffraction (LEED) method, which uses a sophisticated physics model to compare experimental results with spectra computed via a computer simulation. While this approach is highly effective, the computational cost of the simulations can be prohibitive for large systems. In this work, we propose the use of generalized pattern search methods for determining the surface structure of nanosystems. The generalized pattern search method handles both discrete and continuous variables, which allows the simultaneous optimization of the atomic coordinates as well as the chemical identity. We also propose using a simplified physics surrogate in place of the full fidelity physics model. We will present some numerical results based on this simplified physics surrogate within a pattern search method.

New eigensolvers for scalable nano-science simulations. **Andrew Canning** (Lawrence Berkeley National Laboratory, USA) IC/MT2053/010

We present results for new iterative eigensolvers based on conjugate gradients and Jacobi-Davidson in the context of semi-empirical plane wave electronic structure calculations. These new methods give significant speedup over existing conjugate gradient methods used in electronic structure calculations. The new methods will be demonstrated for CdSe quantum dots as well as quantum wires constructed from layers of InP and InAs. These systems are studied in the context of a semi-empirical potential where we typically solve for a few states around the gap allowing us to study large scale nanaosytems. The parallelization of this approach will also be discussed as well as scaling results to large processor counts. Work carried out in collaboration with Osni Marques, Christof Voemel, Lin-Wang Wang, Stanimire Tomov, Julien Langou and Jack Dongarra.

IC/MP355/010: An outlook on scientific software libraries.

Organiser: Osni Marques (Lawrence Berkeley National Laboratory, USA)

The development and implementation of simulation codes on current computer platforms is often a demanding and costly process, due to the complexity of the phenomena to be simulated but also to the proliferation and evolution of computer architectures. The success of such efforts is dictated by the time required to achieve a functional prototype code of the application, and then an optimized production version of the code in order to achieve an optimal usage of the available computational resources. Today, high quality scientific software libraries are widely used in simulation codes.

Despite the recognized value of such libraries, from reducing time to solution to achieving performance, their future is unclear. Demand for more sophisticated simulations requires programmers to be more productive. This pushes toward larger, more integrated and more capable, environments or packages, but with significant disagreement in the scientific community as to the form these should take. At the same time, funding support even for our present-day capabilities has become an acute problem. Funding agencies usually do not fund software support, if they even fund its development. We expect important libraries to be readily available and delivering high performance on all architectures, but computer vendors may not have the resources to do the necessary optimization, especially as packages grow in size and capability. The computation science community is reluctant to pay for libraries, so commercializing software development and support is still largely a cottage industry.

In this minisymposium we propose to bring together different perspectives about these conflicting expectations from users and vendors. We also propose to discuss new technological trends, and most importantly, whether the concept of scientific libraries is obsolete.

Quality assurance: the way forward. **Tim Hopkins** (University of Kent, UK) IC/MT1289/010

I don't believe that software libraries per se are doomed – their usage and interfaces may well change but library codes will still form the core of numerical simulations for the foreseeable future. What does need to change is the way in which library software is deemed fit for purpose; my contact with scientific software as editor for ACM CALGO has convinced me that while the standard of numerical algorithms and techniques has continued to improve the associated software products rarely do the algorithm justice. I would like to see a system whereby software can give a quality rating. This could be partially based on software metrics which would be used to provide indications of code quality, levels of testing, maintenance levels, etc. but would also include peer reviews/comments. It would seem sensible to piggy back such a system on to some form of "son-of-netlib" in the form of a numerical SourceForge; in this way groups of interested users/developers would be able to maintain and improve the software. (This is another area where even good projects (for example, LAPACK and ScaLAPACK) falter – updates/bug fixes etc are very slow at reaching the released packages.)

A forecast of Open Source *and commercial futures for scientific software.* **John Nash** (Université d'Ottawa, Canada) IC/MT1263/010

This talk will look at the infrastructure for scientific software, that is, the procedures, tools, functions and basic knowledge that are used to build scientific software. Examples include compilers, function and subroutine libraries, packages that are used to build other packages, and the collection of papers, reports, and correspondence that collectively provide the background to such work. There appears to be anecdotal evidence – indeed I have some personal experience – that the grant and investment support for such infrastructure has declined in the last two decades. Yet support is needed as new architectures and technologies for scientific computing become available such as inexpensive clusters or grids, particularly those with heterogeneous nodes, and quantum computers. Also, new domains of application, such as some areas of biotechnology and environmental modelling, will require new adaptations or streamlining. The author will attempt to provide some possible futures for scientific software, in particular with a view of both open source projects and commercial ventures.

Do commercial scientific software libraries have a future?. **Ian Reid** (NAG Ltd, UK) IC/MT1848/010

We explore the pros and cons of using commercial scientific software libraries versus open source/DIY. We look at how the marketplace for such software has changed over the last 30 years, how it is used today, and the prospects for the future given the (r)evolution of the hardware.

ACTS: a collection of robust and high-performance software tools. **Osni Marques** (Lawrence Berkeley National Laboratory, USA) IC/MT1780/010

The development of efficient simulation codes is an expensive process that often requires specialized support and information about the available computational resources and software tools. The development effort is usually augmented by the complexity of the phenomena that can be addressed through computers simulations, along with the increase and evolution of computing resources. The US Department of Energy (DOE) Advanced Computational Software (ACTS) Collection comprises a set of DOE-developed software tools, sometimes in collaboration with other funding agencies, and that aim at simplifying the development of computational sciences applications. The talk will describe the functionalities that the tools provide, categories of problems that the tools can solve, availability, portability, and a number of applications that have benefited from the tools, and issues related to long-term support and maintenance.

IC/MP81/010: Uncertainty quantification in computational science and engineering.

Organiser: Fabio Nobile (Politecnico di Milano, Italy)
Co-organiser: Raul Tempone (Florida State University, USA)

Numerical simulations are used every day more as tools to predict the behavior of complex physical systems. Thanks to the fast growing computer power and improved discretization techniques, we are now able to solve more complex systems of partial differential equations in reasonable time.

Yet, many engineering applications, such as groundwater flows, environmental problems, composite materials, reactive flows, just to name a few, are affected by a relative large amount of uncertainty. For instance, the mathematical model used to describe these applications might present uncertainty in the geometry, boundary or initial conditions, model parameters, etc.

Computational Engineering is now facing a new challenge on how to properly incorporate those sources of uncertainty as well as propagate them to the output of numerical simulations.

The Mini-symposium aims at showcasing recent deterministic and probabilistic techniques proposed for Uncertainty Quantification, including Stochastic Galerking, Stochastic Collocation, Stochastic perturbation, Monte Carlo techniques, sensitivity analysis, worst-case scenario, fuzzy sets, etc.

Sparse wavelet methods for operator equations with stochastic data. **Christoph Schwab** (ETH Zürich, Switzerland) IC/MT369/010

Let $A: V \to V'$ be a strongly elliptic operator on a d-dimensional manifold D. An operator equation $Au = f$ with stochastic data f is considered. The goal of the computation is the mean field and higher moments $\mathcal{M}^1 u \in V$, $\mathcal{M}^2 u \in V \otimes V$, $\ldots, \mathcal{M}^k u \in V \otimes \cdots \otimes V$ of the solution.

We discretize the mean field problem using a FEM with hierarchical basis and N degrees of freedom. We present a Monte-Carlo algorithm and a deterministic algorithm for the approximation of the moment $\mathcal{M}^k u$ for $k \geq 1$.

The key tool in both algorithms is a *sparse tensor product* space for the approximation of $\mathcal{M}^k u$ with $O\left(N(\log N)^{k-1}\right)$ degrees of freedom, instead of N^k degrees of freedom for the full tensor product FEM space.

A sparse Monte-Carlo FEM with M samples (i.e., deterministic solves) is proved to yield approximations to $\mathcal{M}^k u$ with a work of $O(MN(\log N)^{k-1})$ operations. The solutions are shown to converge with the optimal rates with respect to the number N of Finite Element degrees of freedom and the number M of MC samples.

The deterministic FEM is based on hypoelliptic equations for $\mathcal{M}^k u$ in $D^k \subset R^{kd}$. Their Galerkin approximation using sparse tensor products of the FE spaces in D allows approximation of $\mathcal{M}^k u$ with $O\left(N(\log N)^{k-1}\right)$ degrees of freedom converging at an optimal rate (up to logs). For nonlocal operators wavelet compression of the operators is used.

The linear systems are solved iteratively with multilevel preconditioning. This yields an approximation for $\mathcal{M}^k u$ with at most $O\left(N(\log N)^{k+1}\right)$ operations.

Applications of the method include $O(N)$ algorithms for the second order statistics of solutions to elliptic problems in domains with random boundary.

This is joint work with Tobias von Petersdorff (Univ. Maryland, College Park).

Stochastic collocation methods for elliptic PDEs with random input data. **Raul Tempone** (Florida State University, USA), Fabio Nobile (Politecnico di Milano, Italy), Clayton Webster (Florida State University, USA) IC/MT3389/010

We present a stochastic-collocation method to solve partial differential equations with random coefficients and forcing terms (input data of the model). The input data are assumed to depend on a finite number of random variables. The method consists in a Galerkin approximation in space and a collocation in the zeros of suitable tensor product orthogonal polynomials (Gauss points) in the probability space and naturally leads to the solution of uncoupled deterministic problems as in the Monte Carlo approach.

We will present collocation techniques based on full anisotropic tensor product grids as well as isotropic or anisotropic sparse grids based on the Smolyak construction. The last approach is particularly attractive in the case of input data obtained as truncated expansions of random fields, since the anisotropy can be tuned on the decay properties of the expansion We will present *a priori* and *a posteriori* ways to chose the anisotropy of the sparse grid which are extremely effective in some situations.

We will also present rigorous convergence results in all cases as well as numerical examples where we compare the different approaches with the more traditional Monte Carlo technique. In particular, the sparse grid approach, with a properly chosen anisotropy seems to be very efficient and superior to all the others also when a moderately large number of input random variables is considered.

A mapping approach for the numerical solution of PDEs on stochastic domains. **Davide Fransos** (Politecnico di Torino, Italy), Claudio Canuto (Politecnico di Torino, Italy) IC/MT2408/010

The present work focuses on the numerical solution of stochastic partial differential equations of elliptic type, posed in a domain whose boundary is described by random variables. Possible solution approaches are based on the Fictitious Domain method [2] and on stochastic mappings [3]. Following the latter, a Polynomial Chaos (PC) expansion expresses the stochastic parametrization of the boundary. Then, it is possible to extend the parametrization inside the domain, i.e., to map the random domain onto a fixed one: the PDE of interest is converted into a new one, posed in a non-random domain but with random coefficients and data (recent results for such equations can be found in [1]). Discretization is accomplished by h-type finite elements in the deterministic variables and orthogonal polynomial projection in the stochastic variables. In the case of a small number of PC variables, the discrete variational formulation features a Galerkin projection onto complete tensor-product spaces of stochastic variables and tensor-product numerical integration in these variables. The resulting scheme is equivalent to a collocation scheme, i.e., to a non-intrusive treatment of stochasticity. This yields a very efficient method, e.g. in comparison with Monte Carlo methods. When the number of PC variables becomes larger than a certain value, the need for "sparse" quadratures arises. The latter case is considered herein.

Error estimation and adaptive computation for elliptic problems with randomly perturbed coefficients and data. **Axel Målqvist** (UC San Diego, USA), Donald Estep (Colorado State University, USA), Simon Tavener (Colorado State University, USA) IC/MT1805/010

Uncertainty in data and coefficients has important consequences for the solutions of otherwise deterministic elliptic problems. Developing efficient methods for understanding the effects of uncertainty is a significant problem in many practical applications. Such uncertainty might arise for example from error in experiments used to measure parameter values, or as a result of coupling to other physical systems. In such settings, the uncertainty is best described as random in nature. This leads to the problem of describing the response in a quantity of interest computed from the solution resulting from the stochastic variations in parameters and data. This is a difficult problem for a number of reasons for example computing a large number of samples is usually prohibitively expensive and numerical error typically varies as parameters and data vary.

We develop and analyze an efficient numerical method for computing the response of a quantity of interest derived from the solution of an elliptic problem with randomly perturbed coefficients and data. We use a variational analysis based on the adjoint operator for problems with uncertainty in the data and boundary conditions. For problems with uncertainty in the diffusion coefficient, we construct a piecewise constant approximation to the random perturbation then use domain decomposition to decompose the problem into sub-problems on which the diffusion coefficient is constant. To compute local solutions of the sub-problems we truncate the infinite series for the matrix inverse. Finally, we derive *a posteriori* error estimates that take into account all the sources of error and derive a new adaptive algorithm that provides a quantitative way to distribute computational resources.

IC/MP412/010: Uncertainty quantification in computational science and engineering, III.

Organiser: Fabio Nobile (Politecnico di Milano, Italy)

Numerical simulations are used every day more as tools to predict the behavior of complex physical systems. Thanks to the fast growing computer power and improved discretization techniques, we are now able to solve more complex systems of partial differential equations in reasonable time.

Yet, many engineering applications, such as groundwater flows, environmental problems, composite materials, reactive flows, just to name a few, are affected by a relative large amount of uncertainty. For instance, the mathematical model used to describe these applications might present uncertainty in the geometry, boundary or initial conditions, model parameters, etc.

Computational Engineering is now facing a new challenge on how to properly incorporate those sources of uncertainty as well as propagate them to the output of numerical simulations.

This mini-symposium aims at showcasing recent deterministic and probabilistic techniques proposed for Uncertainty Quantification, including Stochastic Galerking, Stochastic Collocation, Stochastic perturbation, Monte Carlo techniques, sensitivity analysis, worst-case scenario, fuzzy sets, etc.

Uncertainty quantification using probability logic and its application to robust predictive modelling of systems. **James Beck** (California Institute of Technology, USA) IC/MT3591/010

Probability can be viewed as a multi-valued logic that extends Boolean propositional logic to the case of incomplete information. The key idea is that the probability $P(b|c)$ of a statement b, given the information in statement c, is a measure of how plausible b is based on c. Boolean logic deals with the special case of complete information where the truth or falsity of b is known from c. This interpretation is consistent with the Bayesian one that probability repesents a degree of belief in a statement. Kolomogorov's axioms for probability, which are neutral with respect to interpretation of the probability measure, are a special case where the statements refer to sets. Probability logic provides a rigorous unifying framework for treating modeling uncertainty, along with excitation uncertainty, when using models to predict the response of a system. This paper gives an overview of its foundations and its application to quantifying uncertainty for predictive modeling of systems. The key concept of a Bayesian model class will be described, which is a set of possible probabilistic predictive models for a system together with a probability distribution over this set to quantify the plausibility of each model. Based purely on the probability axioms, a Bayesian model class leads to both prior (initial) and posterior (updated using test data) robust predictive models. Since there is always uncertainty in choosing a model class to represent a system, one can also choose a set of candidate model classes. The probability axioms then lead naturally to prior and posterior hyper-robust predictive models. The challenge in implementations is that integrals over high-dimensional parameter spaces are usually involved that cannot be evaluated in a straight-forward way. Useful computational tools are asymptotic approximations and stochastic simulation based on Markov Chain Monte Carlo methods. Illustrative examples will be presented based on the work of the author and his colleagues.

Tools for model validation based on incomplete data. **Helmut Pradlwarter** (Universität Innsbruck, Austria) IC/MT2397/010

Data to establish probability distributions to describe the variability of some physical properties is quite often very scarse and measurements to increase the sample size are expensive. Under such circumstances, there is little credibility for any *a priori* selected type of distribution. Moreover, the variability of possible distributions due to the lack of sufficient data, is generally ignored by using standard parameter estimation procedures such as the methods based on moments or the Maximum Likelihood. In this paper the use of kernel densities is proposed, where the dispersion of the kernel is a quantitative function of the number of available data points and the required confidence level. Hence, the tails of the distribution, which might be decisive for the reliability assessmnet, will be established as a function of the available number of data point and a reasonable confidence that the probability in the tails will not be higher as assumed. Kernel densities are especially suitable to assign joint probability distributions to data with several components, where the observed correlation among the components must be respected which is usually very cumbersome using traditional approaches. The proposed approach will be demonstrated by applying it for insuffient data provided in the "Model validation problem: Static frame problem", proposed in [1], where a bivariate probability distribution is needed to assess the reliability by a probabilistic approach. Once the joint distribution has been established, an appropriate physical model to describe the variability of a random field, which is in

agreement with the joint distribution, is discussed. The problem will be solved by using a Monte Carlo based optimization procedure.

Dynamic assessment of uncertain mechanical designs based on the fuzzy finite-element method. **Dirk Vandepitte** (Katholieke Universiteit Leuven, Belgium), David Moens (Katholieke Universiteit Leuven, Belgium) IC/MT2455/010

The continuous exponential growth of computational capabilities of modern computers clearly has an impact on the use of the numerical simulation techniques like the finite element (FE) method for engineering purposes. On the one hand, this evolution enables the use of very detailed and hence large FE models. Simultaneously, this evolution has paved the way for a number of computationally intensive analysis techniques derived from the classical FE technique (non-linear analysis, multiphysics...). Especially in the context of numerical design procedures, non-deterministic FE analysis has become a very important issue in the search for valuable utilisation of the available computational resources, as it provides in a cheap and fast tool to assess a new design at a very early stage in its development. This work focuses on the use of the fuzzy finite element method for dynamic design assessment of uncertain mechanical structures through a non-deterministic numerical analysis. The first part consists of a general theoretical discussion on the use of the fuzzy concept in finite element analysis. Next, an overview of recent implementation strategies of the fuzzy finite element code is presented, focusing more specifically on the dynamic behaviour of the design (eigenfrequencies, dynamic responses and acoustic radiation). In order to indicate the added value of the fuzzy finite element method in design, the possible application of the method in a typical product design process is discussed. Finally, the applicability is illustrated through a number of industrially sized design problems.

Random-matrix theory for stochastic structural dynamics. **Sondipon Adhikari** (University of Bristol, UK) IC/MT3523/010

Uncertainties need to be taken into account for credible results from high fidelity, physics and engineering-based numerical simulations. As a result, the quantification and propagation of uncertainties play a crucial role in today's predictive engineering science. Uncertainties can be broadly divided into *parametric uncertainty* (inherent variability/data uncertainty) and *nonparametric uncertainty* (lack of knowledge/model uncertainty). Within the past three decades the deterministic finite element method has been generalized to consider parametric uncertainties in a systematic manner by means of the Stochastic Finite Element Method (SFEM). In the context structural dynamics, using SFEM one usually obtains the random mass, stiffness and damping matrices. More recently a systematic approach to model nonparametric uncertainty is proposed. Using this method one can obtain the probability density function of the system matrices. Therefore, both parametric and nonparametric uncertainty modelling lead to matrix variate distributions describing the system matrices of a linear dynamic system. In this paper it is first proved that both parametric and non-parametric uncertainty can be modelled using a unified matrix variate distribution (similar to a noncentral Wishart distribution). Parametric and nonparametric uncertainty models can be identified as special cases of this general distribution. Once the random system matrices are 'known' via this distribution, using the random matrix theory exact analytical methods have been proposed for the solution of a set of *random algebraic equations* ($\mathbf{K}\mathbf{y} = \mathbf{f}$) and the *random eigenvalue problem* ($\mathbf{K}\phi_j = \lambda_j \mathbf{M}\phi_j$).

Polynomial-chaos expansion of a particle-mesh method for uncertainty quantification in vortical flow. **Olivier Le Maître** (Université de Evry, France), Omar Knio (Johns Hopkins University, USA) IC/MT2263/010

We present a new mesh-particle scheme for uncertainty propagation in the incompressible 2D Navier-Stokes equations in the Boussinesq limit. The scheme incorporates a polynomial chaos (PC) expansion of the flow variables into a Lagrangian particle approximation of the governing equations. The scheme relies on a single set of Lagrangian particles which are convected by the mean flow velocity, while PC representations of their strengths (circulation and temperature) are updated to account for the uncertainty in diffusive and convective effects. An integral approximation of the stochastic coupling terms is derived following the framework of the deterministic particle strength exchange method. This integral approximation yields an algorithm which is stable (even for infinite Péclet numbers) and conservative at the discrete level.

Thanks to the usage of a unique set of particles for all the stochastic modes, improved algorithms devised for the deterministic particle methods can be readily implemented, including mesh-particle methods and adaptive remeshing techniques. These result in a method that combines the advantages of the particles discretization with the efficiency of PC expansions.

Numerical examples are presented which demonstrate the effectiveness of the method to diffusion or convection dominated problems involving significant uncertainty levels, a large number of particles, and high-order PC expansions.

Anisotropic sparse grid stochastic collocation methods for nonlinear partial differential equations with random input data. **Clayton Webster** (Florida State University, USA), Raul Tempone (Florida State University, USA), Fabio Nobile (Politecnico di Milano, Italy) IC/MT3643/010

This work analyzes an anisotropic sparse grid stochastic collocation method for solving several nonlinear partial differential equations with random coefficients and forcing terms (input data of the model). Here, we especially address the situation where the input data are assumed to depend on a moderately large number of random variables, where in general the *curse of dimensionality* is encountered. The Sparse Grid Stochastic Collocation method we utilize was first proposed and analyzed in [Nobile-Tempone-Webster, Technical report #85, MOX, Dipartimento di Matematica, 2006] and extending to anisotropic sparse grids in [Nobile-Tempone-Webster, In preparation]. These approaches consist of a Galerkin approximation in space and a collocation, in probability space, at the zeros of sparse tensor product spaces uti-

lizing either Clenshaw-Curtis or Gaussian interpolants. As a consequence of the collocation approach our techniques naturally lead to the solution of uncoupled deterministic problems as in the Monte Carlo method.

We provide a rigorous convergence analysis and demonstrate exponential convergence of the "probability error" with respect of the number of Gaussian points in each direction in the probability space, under some regularity assumptions on the random input data. However, if the number of random variables is large, the construction of the full tensor product spaces becomes infeasible, since the dimension of the approximating space grows exponentially fast with the number of random variables.

In such cases, this work utilizes anisotropic sparse tensor product spaces constructed from the Smolyak algorithm utilizing suitable abscissas. We also provide a rigorous convergence analysis of the fully discrete problem and demonstrates: (sub)-exponential convergence of the "probability error" in the asymptotic regime and algebraic convergence of the "probability error" in the pre-asymptotic regime, with respect to the total number of collocation points. Numerical examples exemplify the theoretical results and are used to compare this approach with several others, including standard Monte Carlo. In particular, for moderately large dimensional problems, the sparse grid approach, with properly chosen anisotropy, seems to be very efficient and superior to all examined methods.

Multigrid-based preconditioners for stochastic Galerkin formulation of the mixed steady-state diffusion problem. **Catherine Powell** (University of Manchester, UK) IC/MT4555/010

Fluid flow in porous media is often modelled under the assumption that the conductivity coefficients are known at every spatial location. However, simulations based on such oversimplifications cannot provide quantification of probabilities of unfavourable events. Stochastic Finite Element Methods (SFEMs) provide a framework for incorporating statistical information about spatial variability in the conductivity coefficients into computer simulations in such a way that comprehensive probabilistic information about the fluid velocity and pressure is obtained. Specifically, the conductivity coefficients and solution variables are represented as random fields.

SFEMs give rise to very large systems of linear equations and consequently have suffered from bad press. We report on fast, robust linear algebra techniques and preconditioning schemes based on multigrid methods, for solving the stochastic Galerkin formulation of the Darcy flow problem (the steady-state diffusion problem in mixed form) which leads to systems of saddle-point type. Note that we do not solve the primal formulation of this standard elliptic problem. We consider both the (easier) case where doubly orthogonal stochastic basis functions are applied leading to a large number of small deterministic solves and the more challenging case where one large coupled system has to be solved, either due to the choice of a standard orthonormal stochastic basis or due to the presence of a stochastically non-linear random field coefficient. We present some comparisons with the traditional Monte Carlo approach on test problems and show numerical results produced with the mixed SFEM for a realistic flow problem.

Part of this work was done in collaboration with Elisabeth Ullmann and Oliver Ernst at TU Bergakademie Freiberg and David Silvester at the University of Manchester.

Stochastic Krylov-subspace methods for flow in random porous media. **Hector Klie** (University of Texas at Austin, USA), Mary Wheeler (University of Texas at Austin, USA), Adolfo Rodriguez (University of Texas at Austin, USA) IC/MT1490/010

The present work establishes a comparative analysis of different Krylov-based methods for assessing uncertainty in porous media flow. We distinguish two main approaches: (1) stochastic reduced basis methods, and (2) stochastic perturbation methods. The former relies on the construction of an orthogonal basis from which projectors may be realized to perform the uncertainty analysis on a lower-dimensional space. These projection methods may be either Krylov-based (namely, SRBM), as proposed by P.B. Nair, A.J. Keane and other collaborators, or POD-based, as proposed by some other authors. Both of these two methods have close connections with model reduction techniques developed in optimal control theory.

Stochastic perturbation approaches are based on the idea of expressing input and corresponding outputs in terms of stochastic and perturbative polynomial expansions. By grouping terms and moments of the same order, the original stochastic equation is replaced by successive (and parallel) solutions of a set of deterministic equations. The contributions of these solutions are gathered to reconstruct the solution and different stochastic moments associated with the phenomena response. Among these approaches we highlight the Krylov–Karhenun–Loeve moment equation (KKLME) approach for the solution of stochastic PDEs arising in large-scale porous media flow applications. The use of Krylov methods here focuses on the treatment of systems with multiple right-hand sides with block seeded deflation methods.

We provide a set of numerical experiments illustrating the capabilities of SRBM and KKLME on different permeability field distributions for one- and two-phase flow formulations.

IC/MP103/010: Uncertainty quantification in computational science and engineering, II.

Organiser: Fabio Nobile (Politecnico di Milano, Italy)
Co-organiser: Raul Tempone (Florida State University, USA)

Numerical simulations are used every day more as tools to predict the behavior of complex physical systems. Thanks to the fast growing computer power and improved discretization techniques, we are now able to solve more complex systems of partial differential equations in reasonable time.

Yet, many engineering applications, such as groundwater flows, environmental problems, composite materials, reactive flows, just to name a few, are affected by a relative large amount of uncertainty. For instance, the mathematical model used to describe these applications might present uncertainty in the geometry, boundary or initial conditions, model parameters, etc.

Computational Engineering is now facing a new challenge on how to properly incorporate those sources of uncertainty as well as propagate them to the output of numerical simulations.

The mini-symposium aims at show-casing recent deterministic and probabilistic techniques proposed for Uncertainty Quantification, including Stochastic Galerking, Stochastic Collocation, Stochastic perturbation, Monte Carlo techniques, sensitivity analysis, worst-case scenario, fuzzy sets, etc.

Uncertainty quantification for chaotic fluid dynamics. **James Glimm** (SUNY at Stony Brook, USA) IC/MT414/010

Chaotic flows are unstable on all length scales and display problematic convergence properties, because new phenomena emerge under mesh refinement. We develop feature extraction methods for shock and mixing dominated flows. We show that the large scale descriptions of the features converge numerically and determine orders of convergence. This is an essential step in uncertainty quantification for chaotic fluid dynamics.

Multiscale stress assessment in random heterogeneous media. **Robert Lipton** (Louisiana State University, USA) IC/MT2516/010

In this talk we discuss new methods for the assessment of the local stress field inside stochastically defined media. Here we show how to make progress on this problem when the length scale of the heterogeneities are smaller than the characteristic wavelength of the boundary data. We show how to apply new optimal lower bounds on local field quantities in order to characterize local stress fluctuations in terms of the statistics of the microgeometry.

Parametric models for processes with continuous samples and applications to linear random vibration. **Mircea Grigoriu** (Cornell University, USA) IC/MT3340/010

Most actions on physical systems are non-Gaussian processes that have continuous samples. Since the output of linear systems to non-Gaussian input is usually non-Gaussian, the classical mean and covariance equations of linear random vibration are insufficient for characterizing system output.

There are no general analytical methods for finding the probability law of the output Y of a linear system subjected to an arbitrary non-Gaussian input X. Current analytical methods provide useful information on the probability law of Y for some special classes of input processes, for example, polynomials of filtered Gaussian, Poisson, and Lévy process. Monte Carlo simulation is the only general method for calculating output statistics for linear dynamic systems in non-Gaussian environment. However, current Monte Carlo algorithms can be inefficient if applied to the analysis of relatively large dynamic systems since they obtain samples of Y from samples of X by numerical integration.

A two-step method is proposed for finding response statistics for linear systems subjected to input processes with continuous samples. First, a sequence of parametric models $X_n(t) = \sum_{i=1}^{n} C_i \varphi_i(t)$, $n = 0, 1, \ldots$, is develop for X, where $\{\varphi_i\}$ is a specified collection of continuous functions and $\{C_i\}$ are random variables. Samples of $\{C_i\}$ can be obtained by minimizing the distance between samples of X and X_n. Second, statistics of the output Y of a linear system to an input X are approximated by those of the output Y_n of the linear system to X_n. Since Y_n is linear in $\{C_i\}$, its statistics can be obtained simply from samples of $\{C_i\}$. Numerical examples are used to illustrate the construction of the proposed parametric models $\{X_n\}$ and the calculation of statistics of $\{Y_n\}$. It is shown that the parametric models $\{X_n\}$ are accurate and the processes $\{Y_n\}$ provide satisfactory and efficient approximations of Y for sufficiently large values of n.

Uncertainty quantification with random-matrix theory. **Daniel Tartakovsky** (UC San Diego, USA), Sondipon Adhikari (University of Bristol, UK) IC/MT3521/010

Consider diffusion (heat conduction) in a highly heterogeneous environment whose diffusion coefficient (thermal conductivity) D is sampled at a few locations throughout a computational domain. The lack of sufficient information about D renders this problem under-defined and, hence, ill-posed. The problem is routinely regularized by treating D as a random field and the corresponding diffusion equation as stochastic. A key feature of this and other similar stochastic problems is that the randomness of system parameters, such as D, is multiplicative. A solution of such stochastic problems requires a closure approximation in all but a few special cases. This is true for either analytical methods (e.g., a closure by perturbation) or direct statistical methods (e.g., the use of a finite number of realizations in Monte Carlo simulations) or numerical methods (e.g., truncation of infinite series in polynomial chaos expansions). The approximate nature of such solutions formally limits their applicability to either mildly heterogeneous or long-correlated environments.

We propose an alternative approach that, in many applications, obviates the need for a closure approximation. It relies on a representation of a stochastic partial differential equation as a system of coupled linear random algebraic equations. To solve such a problem is to find the inverse of the corresponding random matrix. We present an exact analytical method for the inverse of a real symmetric (in general non-Gaussian) random matrix of arbitrary dimension. The proposed method is based on random matrix theory and utilizes the Jacobian of the underlying nonlinear matrix transformation. For steady-state diffusion, exact expressions for the mean and covariance of the system state is obtained exactly in closed form.

Dual-based error analysis for uncertainty quantification in a chemical system. **Lionel Mathelin** (LIMSI, France), Olivier Le Maître (Université de Evry, France) IC/MT1774/010

This work is concerned with accurate uncertainty quantification (UQ) in a reduced hydrogen oxidation mechanism involving 7 species and 8 reactions. The uncertainty arises from the inexact knowledge of the reaction rates, which are parameterized using 8 independent random variables. A Stochastic Finite Element (SFE) discretization of the random solution is performed using a stochastic basis of piecewise continuous orthogonal polynomials. Due to the stochastic dimensionality of the problem ($N = 8$), it is essential to properly select the SFE basis in order to minimize the approximation error, while maintaining the basis' dimension as low as possible. To this end, a dual-based *a posteriori* error analysis of the SFE approximation is proposed to construct a refinement/coarsening procedure for the representation, which aims at satisfying a prescribed accuracy criterion. The SFE refinement may consist in increasing the order of some stochastic elements (p-refinement), or by splitting some elements into smaller ones (h-refinement). Straightforward isotropic h-refinement is not an option as it would result in an intractable increase of the SFE basis' dimension. Instead, a directional error estimator is proposed for the selection of the stochastic dimensions requiring refinement. If no refinement direction is found, *i.e.* if the SE's error is balanced between all the stochastic dimensions, a p-refinement is applied. On the contrary, the coarsening procedure is used to merge neighboring SFEs having low a posteriori error estimates, when fine stochastic discretization becomes unneces-

sary during the time-evolution of the chemical system.

Numerical tests show that the proposed methodology allows for a fine control of the solution accuracy and significant savings in the computational resources used (CPU and memory requirement).

Global sensitivity analysis: novel settings and methods. **Michaela Saisana** (Joint Research Centre, Italy), Andrea Saltelli (European Commission, Joint Research Centre, Ispra, Italy) IC/MT2128/010

This presentation wants to be an introduction to global sensitivity analysis (SA). Its ambition is to target an audience unfamiliar with global sensitivity analysis, and to give practical hints about the associated advantages and the effort needed.

We shall review some techniques for sensitivity analysis, including those that are not global, by applying them to a simple example. This will give the audience a chance to contrast each method's result against its own expectation of what the sensitivity pattern for the simple model should be. We shall also try to relate the discourse on the relative importance of model input factors to specific questions, such as *"Which of the uncertain input factor(s) is so non-influential that we can safely fix it/them?"* or *"If we could eliminate the uncertainty in one of the input factors, which factor should we choose to reduce the most the variance of the output?"*

A set of worked examples, e.g. application of global sensitivity analysis to real models, is mentioned briefly to illustrate possible useful practices, and reference is given to the existing literature on the subject. Some most common pitfalls will be mentioned as well.

Propagating uncertainty in elliptic problems via a worst scenario analysis. **Fabio Nobile** (Politecnico di Milano, Italy), Raul Tempone (Florida State University, USA), Ivo Babuška (University of Texas at Austin, USA) IC/MT3261/010

Many physical problems are affected by a relatively large uncertainty in the input data and in the coefficients of the underlying mathematical model. In many cases, a full statistical characterization of those uncertainties is impossible to obtain and the only information available is a range where the input data and model coefficients can vary in.

In this work we focus on elliptic PDE's which may feature uncertainty in the coefficients or boundary conditions. Particular attention is devoted to the case of uncertainty in Dirichlet boundary data. We address a deterministic treatment of uncertainty in terms of admissible sets of parameters in the PDE (without introducing any probability measure on these sets) and we aim at identifying the *worst* choice of parameters that leads to the maximum uncertainty in some specific quantities of interest.

The proposed technique for uncertainty quantification and worst-case scenario analysis is based on a perturbation method. It is computationally inexpensive and allows one to account for perturbations in infinite dimensional spaces.

We will present a careful error analysis and numerical examples showing the effectiveness of the methodology.

There is an emergence of computational methods for simulating phenomena where the coupling of multiple physical models is essential. The underpinning models typically describe a physical system at different scales, using different variables. In particular, the methods can replace heuristics and empirical observations in coarse scale single physics models by direct numerical simulations of more accurate fine scale models. For example, an atomistic computation may help to evaluate the constitutive equation in a complex fluid. Solving the fine scale equations accurately over relevant macroscopic length and time scales is often too costly. In many cases, sufficient information on the fine scales' influence on the coarse scale dynamics can be obtained by performing spatially localized simulations over short times. This can significantly reduce the numerical complexity so that it is now feasible to treat problems that could not be handled previously in areas such as complex fluids, defect formation in solids, and certain dynamical systems. However, the coupling also introduces new modeling and numerical errors that should be analyzed carefully. These three integrated minisymposia bring applied computational scientists and numerical analysts together for exchange of recent developments and to stimulate further advances in multiscale modeling and computation.

Atomistic and continuum stochastic models for phase change dynamics. **Anders Szepessy** (Royal Institute of Technology (KTH), Sweden) IC/MT3916/010

The dynamics of dendritic growth of a crystal in an undercooled melt is determined by macroscopic diffusion-convection of heat and capillary forces acting on length scales compared to the nanometer width of the solid-liquid interface. Its modeling is useful for instance in processing techniques based on casting. The phase field method is widely used to study evolution of such microstructures of phase transformations on a continuum level; it couples the energy equation to a phenomenological Allen-Cahn/Ginzburg-Landau equation modeling the dynamics of an order parameter determining the solid and liquid phases, including also stochastic fluctuations to obtain the qualitative correct result of dendritic side branching. This lecture presents some ideas, in the spirit of Lax equivalance theorem, to derive stochastic phase field models from atomistic formulations by coarse-graining molecular dynamics and kinetic Monte Carlo methods.

Dynamic density functional theory (DDFT) for nucleation and growth of crystals: atomistic simulations on diffusive time scales. **Axel Voigt** (FZ caesar, Germany) IC/MT3970/010

Classical density functional theory (DFT) is a very successful theory to describe thermdynamics and equilibrium structures of fluids. It is based upon a minimization principle for a free energy density functional and determines the equilibrium ensemble average one body density profile of a classical fluid. Given the success of DFT, it is very appealing to construct a dynamical theory from it. To obtain en equation of motion for the one-body density profile $\rho(\mathbf{x},t)$ an ensemble average over the possible configurations of the system at time t, given an ensemble at $t=0$ is needed. It is assumed that the gradient of the chemical potential $\nabla\mu(\mathbf{x},t)$ is the thermodynamic driving force for the particle current $\mathbf{j}(\mathbf{x},t) = -\Gamma\nabla\mu(\mathbf{x},t)$, where Γ is a mobility function. μ is given by the functional derivative of the Helmholtz free energy functional with respect to the density profile. All together give the continuity equation $\partial_t\rho(\mathbf{x},t) = -\nabla\cdot\mathbf{j}(\mathbf{x},t)$, and provide the basis for DDFT. Equations of this form have been used is various fields and their agreement with results from Brownian dynamics simulations have generally been very good. We are here interested in the dynamics of freezing, in the theoretical understanding of nucleation and the subsequent growth of crystals. In this context the emergence of an ordered phase can be viewed as a transition to a phase in which $\rho(\mathbf{x},t)$ is highly non-homogenous and possesses the spacial symmetries of the crystal. Appropriate truncation of higher order correlation functions in the free energy functional lead to a closed system which forms a higher order nonlinear PDE for $\rho(\mathbf{x},t)$. We thus have constructed a model on an atomistic resolution, which operates on diffusive time scales. Numerical results based on finite elements will be shown to study nucleation and grain growth in BCC and FCC crystals.

A statistical continuum theory of dislocations. **Thomas Hochrainer** (Fraunhofer IWM Freiburg, Germany), Daniel Weygand (Universität Karlsruhe, Germany), Peter Gumbsch (Fraunhofer IWM Freiburg, Germany), Michael Zaiser (University of Edinburgh, UK), Ferenc Csikor (Eötvös Loránd Tudománygyetem, Hungary) IC/MT3873/010

We recently proposed a second order dislocation density tensor which makes the distinction between geometrically necessary and statistically stored dislocations dispensable. It is termed of second order because it contains information on the curvature of the dislocations. We will discuss in detail how this dislocation density tensor is used to derive a statistical continuum theory of dislocations. Furthermore the incorporation of dislocation sources into the framework shall be discussed. Discrete dislocation simulations were used to determine pair correlations in dislocation systems and to derive physically based laws for the evolution and activation of dislocation source.

A multiscale method for epitaxial growth. **Russel Caflisch** (University of California, Los Angeles, USA), Yi Sun (Courant Institute, NYU, USA), Björn Engquist (University of Texas at Austin, USA) IC/MT4989/010

We investigate a heterogeneous multiscale method (HMM) for interface tracking and apply the technique to the simulation of epitaxial growth. HMM relies on an efficient coupling between macroscale and microscale models. When the macroscale model is not fully known explicitly or not accurate enough, HMM provides a procedure for supplementing the missing data from a microscale model. Here we design a multiscale method that couples kinetic Monte-Carlo (KMC) simulations on the microscale with the island dynamics model based on the level set method and a diffusion equation. Numerical results for island growth and step edge evolutions show improved efficiency over pure KMC simulations while keeping the KMC modeling of the internal boundary conditions.

Multiscale modeling of fluids. **Weiqing Ren** (New York University, USA) IC/MT2285/010

I will present multicale modeling and computation of complex fluids and microfluidics.

Numerical simulation of nucleation and phase separation coupled with crystallization. **Pingwen Zhang** (Peking University, PR China) IC/MT1806/010

The kinetics of liquid–liquid phase separation and crystallization are simulated based on the double temperature-quench experiments through the time-dependent Ginzburg–Landau equations. Numerical simulations demonstrate that our model can successfully reveal the experimental observations, especially the mechanism of *fluctuation assisted nucleation* in the crystallization process which has been proposed by Han's group in the experimental measurements for the statistical copolymer blends of poly (ethylene-co-hexene) (PEH) and poly (ethylene-co-butene) (PEB). We will also introduce new numerical methods to study the equilibrium states and the nucleation in copolymer melts. We propose a new numerical method which can adjust the periodical region of the equilibrium states automatically. The main idea is to treat the shape of the simulation box as a variable, and then transform the region to a unit box. Although the numerical results are achieved under the Landau–Brazovskii model, it is a general method, and the main advantage of our method is that it can be easily planted in any other theoretic frame like self-consistent field theory. The understand-

ing of the equilibrium state provides the foundation to study the nucleation. Nucleation is the decay of a metastable state via the thermally activated formation and subsequent growth of droplets of the equilibrium phase. We will consider the nucleation in diblock copolymer melts, whose equilibrium phases are well understood. We apply a new numerical method, called the string method, to compute the minimum energy path (MEP). Then from the MEP, we find the size and shape of the critical droplet and the free-energy barrier to nucleation.

Computational studies of nematic liquid crystalline polymers in planar shear flow. **Carlos García-Cervera** (UC Santa Barbara, USA), Hector Ceniceros (University of California, Santa Barbara, USA) IC/MT3241/010

We present fully three-dimensional numerical simulations of the dynamics of the Doi-Marrucci-Greco model for nematic liquid crystals. The model couples the Smoluchowski equation for the orientational distribution function with the Navier-Stokes equations, via a closure approximation. The simulations show the formation and dynamics of roll cells and disclinations, and are in both qualitative and quantitative agreement with recent experiments.

The work presented has been carried out in collaboration with Dr. Harley Klein (Leeds University), Prof. H.D. Ceniceros (UCSB), and Prof. L.G. Leal (UCSB).

Multiscale simulations of dense fluids. **Petros Koumoutsakos** (ETH Zürich, Switzerland) IC/MT1545/010

We discuss the coupling of Molecular Dynamics and continuum models (Navier Stokes and Lattice Boltzmann) for the simulation of liquids. A novel, interface forcing term is introduced to match atomistic and continuum simulations. We demonstrate that this interface forcing term can be extended to particle simulations, such as Dissipative Particle Dynamics, where material properties are distorted in the absence of periodicity. Results of benchmarks problems and flows over nanopatterened surfaces demonstrate the advantages and drawbacks of this approach.

Coupling atomistic and continuum models. **Weinan E** (Princeton University, USA) IC/MT3912/010

I will discuss the recent work with Xiantao Li and Weiqing Ren on coupling atomistic and continuum models for modeling solids and fluids. I will discuss issues of stability of numerical algorithms and accuracy across the atomistic-continuum interface. In particular, I will discuss how to treat thermal noise and the effect of statistical noise.

Deterministic spectral solvers for non-conservative non-linear Boltzmann transport equation. **Irene Gamba** (University of Texas at Austin, USA) IC/MT3678/010

We present the implementation of spectral deterministic solvers for non-linear Boltzmann transport problems capable to model energy dissipative flows, such granular gases or elastic gases in presence of thermostat, where non-Gaussian (NESS) states appear as stable homogeneous long time limits. Under these states there are no reliable hydrodynamic systems as asymptotic limits of Boltzmann type equations.

A novel characteristic of this computational approach is the enforcement of conserved quantities by Lagrange multipliers, that makes it work for both energy conservation and energy dissipation as well.

This is work in collaboration with Harsha Tharkabhushanam

Modeling and simulation of micro- and rarefied-gas flow. **Manuel Torrilhon** (ETH Zürich, Switzerland) IC/MT2985/010

Many applications in physics and engineering consider instationary processes of non-equilibrium gas flows in which standard thermodynamics is not valid. Examples range from rarefied gas dynamics to micro-flows in small-scale devices. In these cases the density or scale is so small that the particles of the gas do not collide often enough to produce a thermalized equilibrium. This is often described by the ratio between the mean free path and a macroscopic scale (Knudsen number) which becomes large in non-equilibrium flows.

During this talk we will discuss the mathematical derivation of continuum equations for non-equilibrium gases, based on kinetic gas theory and Boltzmann's equation. A new approach will be presented, which performs an asymptotic expansion around a fixed non-equilibrium. The new equations are highly accurate and fully stable in contrast to common models (Navier-Stokes, Fourier, Chapman-Enskog, Grad, Burnett, etc).

Additionally, some results for applications, like shock wave profiles and shock-density-interactions, will be shown.

Phase transition of a thermally driven Allen–Cahn equation, and solution of the associated optimal control problem. **Mattias Sandberg** (Universitetet i Oslo, Norway) IC/MT4964/010

We will discuss a model problem for phase transitions of a spatially extended system, an Allen-Cahn/Ginzburg-Landau equation perturbed by a small noise term. Via the theory of rare events the probability of transition between the two stable equilibria is, in the limit of vanishing noise, given by the minimizer to an action functional. This minimization may be viewed as an optimal control problem involving the Allen-Cahn equation. A method for approximation of this control problem, including discretization in space and time, is presented. Convergence is proved by employing the Hamilton-Jacobi equations for both the discretized and the original problems, the latter being defined on a space of infinite dimension. The transition proceeds via one or more nucleation events, followed by propagation of domain walls, which will be shown by numerical calculations.

There is an emergence of computational methods for simulating phenomena where the coupling of multiple physical models is essential. The underpinning models typically describe a physical system at different scales, using different variables. In particular, the methods can replace heuristics and empirical observations in coarse scale single physics models by direct numerical simulations of more accurate fine scale models. For example, an atomistic computation may help to evaluate the constitutive equation in a complex fluid.

Solving the fine scale equations accurately over relevant macroscopic length and time scales is often too costly. In many cases, sufficient information on the fine scales' influence on the coarse scale dynamics can be obtained by performing spatially localized simulations over short times. This can significantly reduce the numerical complexity so that it is now feasible to treat problems that could not be handled previously in areas such as complex fluids, defect formation in solids, and certain dynamical systems. However, the coupling introduces new modeling and numerical errors that should be analyzed carefully.

We propose three integrated minisymposia that bring applied computational scientists and numerical analysts together to facilitate the exchange of recent developments and stimulate further advances in multiscale modeling and computation.

Analysis of heterogeneous multi-scale methods. **Björn Engquist** (University of Texas at Austin, USA) IC/MT4195/010

The heterogeneous multi-scale method is a framework for developing computational multi-scale techniques, for example, for coupled atomistic and continuum simulations. The framework is also very useful in the convergence study of a wide class of algorithms for multi-scale problems. We will mainly discuss homogenization problems and stiff dynamical systems.

Numerical integrators for multiscale dynamical systems with stochastic effects. **Eric Vanden-Eijnden** (Courant Institute, NYU, USA) IC/MT1279/010

We will discuss a class of numerical integrators for dynamical systems with multiple time-scales and stochastic effects such as stochastic differential equations or continuous-time Markov jump processes. These integrators build on limiting theorems for singularly perturbed Markov processes and have a cost which is independent of the small parameter measuring timescale separation in the systems – in contrast, the cost of standard integrators would increase as the inverse of this small parameter.

Adaptive stochastic dynamics for the computation of free-energy differences. **Tony Lelièvre** (École Nationale des Ponts et Chaussées, France) IC/MT3742/010

Stochastic dynamics to compute free energy differences are widely used in computational chemistry and biology. Many recent methods rely on complex Markov processes (non-homogeneous or non-linear processes). Examples of such methods are exponential reweighting of non-equilibrium paths (Jarzynski equality) and Adaptive Biasing Force (ABF) techniques. A unifying presentation of adaptive methods is proposed. We also prove the convergence of a certain class of adaptive methods. Finally, we present an efficient implementation of adaptive dynamics using an interacting particle system with birth death processes.

Some numerical studies on the implicit methods for multiscale systems. **Tiejun Li** (Peking University, PR China) IC/MT2683/010

We demonstrate, by a combination of analytical arguments and numerical examples, that implicit stiff ODE (ordinary differential equation) solvers are not effective for dynamical systems with multiple time scales when the quasi-equilibrium distributions for the fast variables are not Dirac distributions. This is due to the fact that such implicit methods cannot correctly capture non-Dirac invariant distributions when the time step size is much larger than the relaxation time of the system.

IC/MP728/010: Multiscale modeling and computation: dynamical systems. #2

Organiser: Yen-Hsi Tsai (University of Texas at Austin, USA)
Co-organiser: Olof Runborg (Kungliga Tekniska högskolan, Sweden)
Co-organiser: Björn Engquist (University of Texas at Austin, USA)

(For abstract, see session #1 above.)

Chebyshev methods for stiff stochastic problems. **Assyr Abdulle** (University of Edinburgh, UK) IC/MT2751/010

Stiff stochastic systems play a major role in a wide range of applications. For problems with scale separation, explicit multiscale methods have recently been proposed. Implicit methods are usually advocated for stiff problems when fast and slow dynamics cannot be separated. In this talk we discuss a new class of explicit methods for the efficient treatment of stiff stochastic problems without scale separation.

This is a joint work with S. Cirilli (Geneva).

Multiscale methods for the wave equation. **Olof Runborg** (Kungliga Tekniska högskolan, Sweden), Björn Engquist (University of Texas at Austin, USA) IC/MT3420/010

We consider the wave equation in a medium with a rapidly varying speed of propagation. We construct a multiscale scheme based on the heterogeneous multiscale method, which can compute the correct coarse behavior of wave pulses traveling in the medium, at a computational cost essentially independent of the size of the small scale variations. This is verified by theoretical results and numerical examples. The work is in collaboration with Bjorn Engquist and Henrik Holst.

A multiscale method for a class of stiff ODEs with polynomial right-hand-side. **Yen-Hsi Tsai** (University of Texas at Austin, USA) IC/MT3374/010

We consider a class of ODE systems with highly oscillatory components. Through resonances among these oscillations, nontrivial slow behavior of a given system is generated. To achieve efficient solution without resolving the oscillations everywhere, the resonances in the system must be consistently modeled. We present our strategy for detection of the resonance and determination of a set of slow variables using the dynamics of the given oscillatory system. The slow variables are then integrated using an algorithm developed under the Heterogeneous Multiscale Method framework.

This is joint work with Bjorn Engquist and Gil Ariel

Application of the heterogeneous multiscale methods to highly-oscillatory ODEs. **Richard Sharp** (University of Texas at Austin, USA) IC/MT2838/010

The Heterogeneous Multiscale Methods (HMM) is a framework for efficiently and accurately treating multiscale problems. Frequently, the macroscopic quantities of interest in a problem depend on the microscopic evolution of a system. Depending on the problem, it may be necessary to fully resolve the microscale, because it is not possible to accurately coarsen this description and write a macroscopic model. In materials science for example, crystal growth depends on the the ease with which a single molecule can be added to the lattice, but semiconductor devices produced this way are bulk materials. A fully resolved atomistic simulation is too computationally expensive to achieve, and even if it were, the result would need further processing to extract the electrical properties of interest. A strength of HMM style algorithms is that they do not require a specific macroscopic model in order to track macroscopic variables. Instead, such algorithms exploit scale separation to extract macroscopic information from a limited number of local microscopic simulations. Significant challenges lie in identifying an appropriate set of macroscopic variables, and in the exchange of information between the different scales of the problem. I will present recent applications of the HMM to highly oscillatory ODEs, including a driven pendulum and more general autonomous stiff systems. In this setting, the highly oscillatory solution to the microscopic problem converges weakly to a relatively smooth average solution, as scale separation is increased. The slow solution can be simulated with a relatively long time step when a self-consistency condition is used to reinitialize the microscopic model after each update of the macroscopic data.

IC/MP256/015: Numerical simulation of plasmas.

Organiser: James Rossmanith (University of Wisconsin, Madison, USA)
Co-organiser: Andrew Christlieb (Michigan State Univsersity, USA)

Plasmas are ionized gases that appear in a wide range of applications including astrophysics and space physics, as well as in laboratory settings such as in magnetically confined fusion. Modeling and understanding the basic phenomenon in plasmas has long been a topic in scientific computing, yet many problems remain far too numerically intensive for modern parallel computers. The main difficulty is that plasmas span a wide range of spatial and temporal scales, requiring modeling tools from both fluid and kinetic theory. This minisymposium aims to give an overview of the state of the art in plasma simulations; and as such, it touches on variety of topics ranging from advanced simulation methods for ideal MHD to fully kinetic simulation techniques. Furthermore, a variety of application areas will be addressed including astrophysics, spacecraft design, and magnetically confined fusion.

Computing the radiation source term in the system of radiation-magnetohydrodynamics in 3D. **Andreas Dedner** (Universität Freiburg, Germany) IC/MT2885/015

In this talk we present a scheme for solving the equations of radiation magnetohydrodynamics (RMHD) in three space dimensions, a non–linear system of balance laws combining the effects of magnetohydrodynamics (MHD) and mon-local energy transport through radiation. The starting point of our presentation is a standard explicit second order finite-volume scheme for the MHD equations on both structured and unstructured locally adapted parallel grids. To add the energy transport through radiation we have to compute the radiation source term in the balance law for the total energy density:

$$Q_{\text{rad}} := \rho\kappa(\rho, T) \int_{S^2} (S(T) - I_\mu)\, d\mu$$

We denote with ρ and T the density and the temperature of the plasma, respectively, and I_μ denotes the radiation intensity in direction $\mu \in S^2$. Since in our application hydrodynamic time scales are much smaller than the time scale in the radiation transport, the radiation intensity is modeled using the stationary radiation trasport (RT) equation:

$$\mu \cdot \nabla I_\mu + \rho\kappa(\rho, T) I_\mu = \rho\kappa(\rho, T) S(T)$$

Solving this equation even for a small number of directions μ leads to a considerable increase in computational cost - at least 70% of the computational cost for the full coupled system is spent in computing the radiation source term. Thus a highly efficient scheme for approximating the radiation source term Q_{rad} is an essential part of any method for solving the fully coupled RMHD equations. This will be the main focus of our presentation. We present results concerning the convergence of the numerical scheme and numerical tests, comparing our *extended short characteristics* scheme with some standard schemes found in the literature, e.g., the discontinuous Galerkin approach. Since the approximation of the radiation intensities in a fixed direction μ is not so crucial as the approximation of the radiation source term Q_{rad} in the energy balance law, we will concentrate on this aspect of the numerical schemes. We conclude our presentation with a study of the parallelization strategy for distributed memory computers that we use in our 3d code.

On electric light arc simulations with MHD. **Manuel Torrilhon** (ETH Zürich, Switzerland) IC/MT3022/015

Light arcs appear as electrical discharges between two conductors with strong difference in potential. The archetype of a light arc is the lightning in a thunderstorm. But light arcs are also found in various engineering applications like circuit breakers. In a light arc the gas is ionized and turned into a plasma with high electrical conductivity that interacts with electric and magnetic fields. Hence, simulations of light arcs are examples for an industrial need of magnetohydrodynamics. This talk will present basic physical characteristics of light arcs with various simplified model problems. The fundamental driving force is the interaction between temperature and electric current. We also discuss the light arc as a multi- physics phenomena. Difficulties are strongly varying electrical conductivity, influence of external fields and radiation transport, as well as turbulence. Parts of the talk will present results from an ongoing project on full scale light arc simulations in the Seminar for Applied Mathematics at ETH Zurich.

IC/MP256/015: Numerical simulation of plasmas. #2

(For abstract, see session #1 above.)

Volumetric point insertion for grid-free Lagrangian particle methods. **Andrew Christlieb** (Michigan State Univsersity, USA) IC/MT2372/015

Plasmas (ionized gases) have rich and complex behavior which often need multiple lines of attack to fully understand their rich dynamics. Depending on the length scales involved, the plasma may be described by either a kinetic or a fluid model, the kinetic model being the more fundamental of the two. In this talk we will give a brief overview of the relation between these two models and then discuss grid-free Lagrangian particle methods for kinetic plasma problems using adaptive volumetric point insertion. Specifically, our talk will discuss the application of this approach to the Vlasov–Poisson system, a kinetic model, and the warm two stream instability. In addition, a comparison with grid-based Lagrangian particle models will be presented. At the end of the talk we will briefly discuss our plans for developing a multi-scale plasma model spanning the entire range of length scales from kinetic to fluid models.

Residual distribution schemes for astrophysical plasmas. **James Rossmanith** (University of Wisconsin, Madison, USA) IC/MT2020/015

An important problem in modern astrophysics is to understand the accretion of ionized gases onto a black hole and the formation of relativistic jets that can sometimes result from this process. Even with significant simplifying assumptions, including that the spacetime is static and that the accreting dust obeys the relativistic MHD equations, accurate numerical computations of such flows are still quite challenging to obtain. Some of the difficulties include the strong curvature of spacetime near the event horizon, the divergence-free condition on the magnetic field, the complex equation structure due to the Lorentz factor, and non-trivial balances between flux gradients and geometric source terms. In this talk we will describe an effort to develop genuinely multidimensional, high-resolution, shock-capturing schemes on unstructured grids for solving the relativistic MHD equations. The resulting method will be applied to several axisymmetric computations of black hole accretion.

Hybrid Monte-Carlo methods for fluid and plasma dynamics. **Russel Caflisch** (University of California, Los Angeles, USA) IC/MT2070/015

For small Knudsen number, simulation of rarefied gas dynamics by the DSMC method becomes computationally intractable because of the large collision rate. To overcome this problem we have developed a hybrid simulation method, combining DSMC and a fluid dynamic description into a single seamless method. The molecular distribution function f is represented as a linear combination of a Maxwellian distribution M and a particle distribution g; i.e., $f = bM + (1-b)g$. The density, velocity and temperature of M are governed by fluid-like equations, while the particle distribution g is simulated by DSMC. In addition there are interaction terms between M and g. The coefficient b is determined automatically, by a thermalization approximation. Numerical results will be presented to demonstrate the validity of this method, as well as the acceleration that it provides over DSMC. This method has been extended to simulation of Coulomb collisions in a plasma. For this extension, the underlying Monte Carlo method is Nanbu's method for Coulomb collisions.

High-resolution central schemes for kinetic and fluid plasma models. **Jorge Balbás** (University of Michigan, Ann Arbor, USA) IC/MT3003/015

In this work we present high-reslution central schemes for two-species plasmas described by the microscopic Vlasov kinetic model and by the macroscopic Euler-Poisson fluid model. While the microscopic model provides a rather accurate description for collisionless plasmas, numerical simulations require the discretization of each component of the velocity field as one more variable in phase space which, in turn, demands considerable computer time and power. Alternatively, one can consider the Euler-Poisson equations, which consist of a hyperbolic system of conservation laws for each species with an inhomogeneous term that coples the two systems through the electric field (Poisson Equaton); a model resulting from taking the first three moments of Valsov equation. Although the description provided by the fluid model is not as accurate as its microscopic counterpart, it is still adequate for many plasma simulations and considerable less computationally expensive to simulate.

Finite volume numerical schemes for both models have been recently developed and employed so as to asess the validity of the fluid model by comparing the results obtained wtih this to those obtained with its kinetic counterpart. To this end, we propose the development of finite volume schemes based on central differencing. Central schemes avoid the costly use of (approximate) Riemann solvers for the fluid model, resulting in simple –yet robust– *black box* type numerical schemes.

IC/MP323/015: Modeling the mechanics of the cardiovascular system.

Organiser: Joakim Sundnes (Simula Research Laboratory, Norway)
Co-organiser: Gerhard Holzapfel (Royal Institute of Technology (KTH), Sweden)

For several decades nonlinear solid mechanics has been applied to the cardiovascular system. A continuous development in mathematical techniques and computer hardware has occurred in parallel with a gradually improved knowledge of biological behavior and material properties of soft tissues. This has allowed scientists to build more and more complex and realistic models of this vital system, and has resulted in increasingly accurate model predictions and improved (patho)physiological understanding, as well as direct applications in clinical practice. Important examples include design of medical devices such as artificial heart valves and heart assist devices, and the development of vital procedures such as heart transplants and bypass surgery. However, in spite of these success stories, there are still many unresolved issues related to both biology-specific formulations and to challenges of modeling the material behavior of soft biological tissues. From a viewpoint of computational mechanics, particular challenges include finite strains, nonlinear elastic or viscoelastic material behavior, anisotropy, fluid-structure interaction and the formulation of contact problems including large sliding. In this minisymposium we address solid mechanics modeling of the cardiovascular system, with particular focus on mathematical and computational aspects. We will touch upon several active research areas, spanning from the development of constitutive relations for passive material behavior, through mathematical modeling of active forces developed in

muscle tissues, to addressing the computational challenges involved in solving systems of strongly nonlinear partial differential equations. We will also describe some of the possible applications of the models for clinical work and biomedical science.

Computational techniques for heart muscle mechanics. **Joakim Sundnes** (Simula Research Laboratory, Norway) IC/MT2292/015

The heart occupies the most central role of the cardiovascular system, with the crucial role of supplying a continuous flow of blood through the vast network of vessels composing the circulatory system. Mathematical models of the heart in health and disease is an increasingly important tool for improving our understanding of this vital organ, and thereby help to reduce health problems and costs related to cardiovascular disorders.

In this talk we give an overview of computational challenges and techniques related to modelling the mechanical function of the heart muscle. Models applied for this purpose vary in complexity from the simplest pressure-volume relations based on a given time varying elastance, to systems of differential equations that give a detailed description of cardiac electromechanical interaction.

The primary focus of the talk will be on finite element modeling of the heart muscle, which includes modeling the passive mechanical properties of the tissue as well as the active muscle contraction and its coupling to electrophysiology. The heart muscle is normally modeled as a hyper-elastic material, with strongly non-linear and anisotropic material behavior. The resulting mathematical model consists of a large-strain elasticity equation, which is coupled to DAE systems that describe electro-chemical reactions on cell level, and also to a system of PDEs that describe the conduction of the electrical signal in the tissue. We discuss some approaches for solving this system, which offer a varying degree of coupling and feedback between electrophysiology and mechanics. We also discuss different approaches for coupling the heart muscle models to the rest of the circulatory system. The latter topic will also be covered in more detail in the other talks of the minisymposium.

Ventricular interaction quantified with a novel multi-scale cardiovascular model. **Roy Kerckhoffs** (UC San Diego, USA), Maxwell Neal (University of Washington, USA), James Bassingthwaighte (University of Washington, USA), Jeffrey Omens (UC San Diego, USA), Andrew McCulloch (UC San Diego, USA) IC/MT3354/015

Ventricular interaction (VI) in the heart is the influence of function of one ventricle on the other. Direct VI (DVI) is modulated through the septum and pericardium, while indirect VI (IVI) is referred to as interaction through the circulation. It is difficult however, to separate VI in components DVI and IVI. To investigate VI, a novel multi-scale model of the canine cardiovascular system was developed, that couples an anatomically detailed 3-D finite element model of the ventricles with a closed loop lumped model of the pulmonary and systemic circulations. Multiple beats of a normal heart were simulated, followed by pulmonary artery constriction (PAC).

Methods

The myocardium had nonlinear passive and dynamic active material properties. Both atria were included in the lumped model as time-varying elastances. Hence, the model encompassed levels of the myocyte, tissue, organ, and system. VI was quantified by computing ventricular co-compliances, i.e. the volumic changes in each ventricle due to a pressure change in the other ventricle (CRL=dVR/dPL and CLR=dVL/dPR). This was done at every time step with finite differences by perturbing ventricular pressures.

Results

CLR and CRL varied throughout the cardiac cycles. After PAC, diastolic values changed acutely from -5.7 to -6.5 ml/mmHg, due to an abrupt change in DVI. Over time, CLR and CRL became more negative (-7.4 ml/mmHg), due to IVI.

Conclusions

- VI was quantified using co-compliances. - Using a novel multi-scale cardiovascular model, VI was investigated. VI increased after PAC. - The model is likely to be useful in investigating VI, among others, in many clinical settings.

Stent modelling: application to percutaneous pulomnary-valve implantation. **Francesco Migliavacca** (Politecnico di Milano, Italy), Silvia Schievano (University College London, UK), Claudio Capelli (Politecnico di Milano, Italy), Lorenza Petrini (Politecnico di Milano, Italy), Gabriele Dubini (Politecnico di Milano, Italy), Philipp Bonhöffer (University College London, UK) IC/MT1463/015

Percutaneous pulmonary valve implantation (PPVI) is a catheter-based technique for treating pulmonary valvular disease. Stent fracture is a recognized complication following PPVI. In our series (n=123) we have seen stent fractures occur in 26 patients: 4/10 patients treated with an early generation device and 22/113 with a new design stent. Many different factors play a role in the generation of device fracture including: stent material and design, the nature of the implantation site and stress induced by the functioning valve. The aim of this work is to study some of the factors responsible for stent fracture, by means of finite element analyses (FEA).

METHODS: All patients underwent X-ray investigation following PPVI, at different intervals of time. When fractures were detected, the exact sites of fractures were analyzed from the X-ray films. CAD model of two different stents were designed on the basis of data supplied from the company. The former is a balloon expandable stent, from platinum-10

RESULTS: At X-rays investigation, the early generation stents led to fractures at the strut intersections. The FEA show that the platinum stent presents highest stresses at the same points, proving that this location is more subjected to fracture. In the new design stent, fractures occurred more frequently next to the ends of gold welds. The model shows as the gold reinforces the crossing sections of the platinum device protecting them from fracture. However, the straight platinum parts of this stent present higher stresses then the device without gold welds, because of the reinforcement itself. Indeed, the gold welds create geometrical and material discontinuities. Therefore, the fracture occurs just distal to the welds.

CONCLUSIONS: The finite element method is an important technique to understand stent behaviour and integrity and may aid device design and material before many prototypes are actually manufactured.

Thin-valve simulations with Lagrange multipliers. **Jean-Frédéric Gerbeau** (INRIA Rocquencourt, France), Nuno Diniz dos Santos (INRIA Rocquencourt, France) IC/MT814/015

We present an approach based on Lagrange multipliers to approximate thin valve movements in an incompressible fluid. This strategy allows very large displacements, can be mixed with an Arbitrary Lagrangian Eulerian formulation and is able to tackle changes in the topology of the problem, such as contact. We propose an efficient partitioned algorithm which keeps the fluid and the structure solvers independent. Moreover the algorithm is able to manage contacts without asuming that the structure solver includes contact capabilities. Numerical validations and comparisons with other methods will be presented.

IC/MP701/015: Numerical and asymptotic methods in kinetic-gas theory.

Organiser: Manuel Torrilhon (ETH Zürich, Switzerland)

Kinetic gas theory is the classical non-equilibrium theory of gases based on Boltzmann's equation. It relies on a stochastic description of the particles of the gas and their coarse-grained interaction. Nowadays, applications of kinetic gas theory can be found over a wide range of fields in science and engineering, like plasmas, granular media, semi-conductors, traffic flow and biological modelling. The various kinetic equations still represent a serious challenge with respect to both mathematical theory and numerical methods.

This minisymposium focuses on asymptotic and computational approaches, especially for Boltzmann's equation. Here, the asymptotic theory considers the derivation of continuum models from the kinetic equation valid for small and moderate non-equilibrium. Scaling parameter is the Knudsen number, ie the ratio of mean free path and macroscopic length. Various models and asymptotic theories have been proposed but stability and accuracy remains difficult to obtain. Computational methods have to handle the high dimensionality due to the phase space description as well as non-trivial collision interactions. Hybrid schemes may be able to combine the efficiency of asymptotic models with the accuracy of direct solvers.

Beyond Navier–Stokes: constructing hydrodynamic models to capture unusual rarefied-gas flow phenomena. **Jason Reese** (University of Strathclyde, UK) IC/MT2988/015

I will describe recent and ongoing work at the University of Strathclyde, Glasgow, Scotland, UK, into the new fluid dynamics needed for very high-speed or micro- and nano-scale gas flows. While these are application areas of emerging technological importance, remarkably there is currently no sufficiently accurate and computationally efficient fluid dynamic model. This is because the conventional Navier-Stokes fluid equations do not allow for the local thermodynamic non-equilibrium that makes the behaviour of these rarefied gas flows uniquely complex.

In this talk I will focus on our work on capturing two fundamental aspects of these flows: gas velocity slip at solid surfaces, and the associated Knudsen layer extending from the solid surface into the flow. I will describe the successes and failures of various hydrodynamic models (derived from kinetic theory) being developed to capture this non-equilibrium flow physics, and give examples of current test applications in both hypersonics and micro gas flow situations.

Stabilizing the Burnett fluid dynamics equations. **Lars Söderholm** (Kungliga Tekniska högskolan, Sweden) IC/MT2992/015

The Burnett equations, the equations to second order in the Knudsen number derived by the Chapman–Enskog method, suffer from the unphysical Bobylev instability. A crucial step in the Chapman-Enskog procedure is the use of the approximate conservation laws to replace some time derivatives by space derivatives, we call them formal time derivatives.

It is, however, consistent with the approximation to partly revert this replacement in the resulting expressions for the viscous pressure and heat current. The formal time derivative (denoted by a subscript 0) of the traceless rate of deformation tensor is replaced by a linear combination of the real time derivative and the formal time derivative (α is a parameter)

$$\frac{D_0\mathbf{S}}{Dt} \to (1-\alpha)\frac{D\mathbf{S}}{Dt} + \alpha\frac{D_0\mathbf{S}}{Dt}$$

It is shown that equations that are stable temporally as well as spatially can be achieved choosing α appropriately. The resulting momentum equation is (dots denote nonlinear Burnett terms)

$$\rho\{\mathbf{1}-(\omega_3-\omega_2)\frac{\mu^2}{p\rho}[\frac{1}{2}(\triangle\mathbf{1}-\nabla\nabla)+\frac{2}{3}\nabla\nabla\}\cdot\frac{D\mathbf{v}}{Dt} = -\nabla p+2\nabla\cdot(\mu\mathbf{S})+\omega_3\frac{\mu^2}{\rho^2}\frac{2}{3}\triangle\nabla\rho+..$$

The use of multiple time scales approximation will also be briefly discussed.

The Boltzmann equation and its fluid-dynamic limits: numerical studies. **Hans Babovsky** (TU Ilmenau, Germany) IC/MT3343/015

Recently, a class of discrete kinetic models have been proposed [1,3] emerging from the Boltzmann equation through the choice of a special hexagonal discretization. These have turned out a useful tool for the (at least qualitative) numerical simulation of rarefied gas dynamics in the transition regime to fluid dynamics [2,3].

The Boltzmann equation allows for a variety of scaling limits ranging from the Euler to the Navier–Stokes equations and covering compressible as well as incompressible flows. A review of recent results is contained in [4]. In the talk we will demonstrate the above model as being capable of approaching the diverse hydrodynamic limits. Thus the whole spectrum of scaling limits is covered by one single algorithm which provides a good basis for comparing flow patterns obtained for different parameter regimes. The talk discusses a couple of test cases.

The lattice-Boltzmann hierarchy: turbulence, microflows and renormalization. **Ilya Karlin** (ETH Zürich, Switzerland) IC/MT3809/015

I will review recent developments [1-5] in the lattice Boltzmann models, with a special emphasis on near-continuum and gas micro-flow simulations. Topics covered include: derivation of the lattice Boltzmann hierarchy of kinetic models, high Reynolds number simulations, exact solutions, thermal models and multi-component mixtures including surface reactions, boundary conditions and implementation issues.

IC/MP38/015: Computational issues in relativistic quantum chemistry.

Organiser: Gabriel Turinici (Université Paris Dauphine, France)
Co-organiser: Mathieu Lewin (Université Cergy-Pontoise, France)

The main goal of this minisymposium is to present various aspects of computational Relativistic Quantum Chemistry. Relativistic Quantum Chemistry aims at modelling and simulating matter at the microscopic scale, taking into account fine effects encountered by the core electrons in heavy atoms (like Gold or Uranium). These effects have to be considered for an accurate description of the chemical behaviour of the corresponding atoms or molecules. Different types of numerical methods have been developed and are used today by chemists or physicists. But one must admit that the understanding of the relativistic models is not as deep as for the models neglecting these effects. Mathematically speaking, the main difficulties are created by the spectrum of the Dirac operator, which is not bounded by below. Mathematical analysis of the undersying models can help to propose more robust and efficient computational procedures to address these problems. The idea of the minisymposium is to put together specialists from different fields, two from mathematics (nonlinear analysis and numerics) and two from quantum chemistry.

Computation of approximate energy states in relativistic quantum chemistry. **Maria Esteban** (Université Paris-Dauphine, France) IC/MT2853/015

In this talk will be presented numerical computations of energy states for Dirac operators appearing in the modelling of atoms and molecules when relativistic effects are taking into account. These computations are done by using an algorithm based on exact variational characterization of the eigenvalues of Dirac operators, with or without the presence of external magnetic fields.

Spontaneous particle creation within the external field approximation of QED. **Nikodem Szpak** (Max-Planck-Institut Potsdam, Germany) IC/MT3160/015

It is expected that strong electromagnetic fields in QED may lead to destabilization of the vacuum, its decay and spontaneous production of an electron-positron pair if the strength of the electric field exceeds some threshold. We study the problem within an external field approximation of QED in presence of time-dependent external fields and define the spontaneous particle creation via the adiabatic limit. We consider some model fields, which we solve analytically or numerically, in order to explain the subtlety of the effect and to recognize problems appearing in its proof. We conclude by characterizing when the effect can exist in a stable way and when it becomes unstable w.r.t. small perturbations."

The quasi-energy formalism of density-functional theory. **Trond Saue** (Ecole Nationale des Ponts et Chaussées, France) IC/MT3169/015

Density-functional theory (DFT) treats electron correlation efficiently at low computational cost and has therefore become the dominant method in the field of theoretical chemistry. The rigorous foundation of DFT was provided by the Hohenberg-Kohn (HK) theorem and its practical realisation by the Kohn-Sham scheme . The HK theorem establishes a one-to-one correspondence between the (non-degenerate) ground state density and an external scalar potential, usually the electrostatic potential of fixed nuclei, and requires a minimisation principle for its proof. The extension to time-dependent phenomena, including the calculation of response properties as well as excitation energies, was established through the Runge-Gross theorem. This theorem establishes a one-to-one correspondence between a time-dependent external scalar potential and the density of any state provided that the exact initial wave function is given. The Runge-Gross theorem uses a Taylor expansion in time of the scalar potential and does not hold for an adiabatically switched-on static potential. As pointed out by van Leeuwen, the definition of a time-dependent exchange-correlation (xc) potential of some action, in analogy with the definition of the static exchange-correlation potential as the functional derivative of the xc energy with respect to the density, may lead to problems with causality. An alternative approach imposes periodic boundary conditions on the external potential and tries to generalize the HK theorem through Floquet theory. It introduces the quasienergy by extension of the Hilbert space by time averaging. A minimisation principle for the quasienergy has been suggested, but not rigorously proven, by Sambe. In my talk I will discuss the challenges in basing time-dependent DFT (TD-DFT) on Floquet theory.

Reduced-basis methods in RQC. **Yvon Maday** (Université Pierre et Marie Curie, France) IC/MT3011/015

Reduced basis methods allow to approximate accurately and rapidly the solution to general partial differential equation by making use of ad'hoc discrete spaces, built in an off line stage and used online to new situations.
These methods have been introduced in different context: structural mechanics, fluid flows, thermal problems and more recently in quantum chemistry context.

We shall present in this talk new results in relativistic context and illustrate the features of this new method.

IC/MP109/015: Undergraduate computational science and engineering education.

Organiser: Peter Turner (Clarkson University, USA)
Co-organiser: Ignatios Vakalis (California Polytechnic and State University, USA)

Computational Science and Engineering (CSE) is a rapidly growing multi-disciplinary area with connections to the sciences, engineering, mathematics and computer science. CSE is a legitimate and important academic enterprise, even if it has yet to be formally recognized by a number of institutions.
The undergraduate arena is the most important segment of the educational pipeline, since it prepares teachers for the HS environment, invigorates students to pursue graduate studies in cutting edge technical fields, and produce a vast number of future employees for industry and the "knowledge based" economy. Thus it is critical that CSE curricula/ programs are a viable option for every undergraduate student.

The minisymposium will concentrate on: i)model programs of undergraduate computational science and computational engineering programs (USA and Europe); ii)sample undergraduate research experiences and connections to curricula; and iii)needs of industry for CSE undergraduate majors. Key ideas from the upcoming SIAM report will be presented. Sufficient time will be alloed for audience interactions and comments.

Internships and work experience in undergraduate CSE education. **Angela Shiflet** (Wofford College, USA), Peter Turner (Clarkson University, USA) IC/MT5014/015

An internship or work experience can be the climax of a CSE undergraduate's education. With exposure to many new ideas, techniques, and applications at another institution, such an experience can greatly broaden and deepen the student's understanding of computational science and make the classroom education more meaningful. Moreover, work with a professional computational science team and contacts made during the summer can greatly enhance opportunities and options available to the CSE undergraduate.

Keeping CSE curricula focussed. **Ulrich Rüde** (Universität Erlangen–Nürnberg, Germany) IC/MT3723/015

The courses of Computational Science and Engineering programs are typically given by a faculty spread across different departments and institutes and therefore by specialists in their own disciplines. These instructors often follow their own scientific interests and not necessarily those of an genuine education in CSE. Thus there is a danger that depending on the political constellation at a university, a CSE program may degenerate away from CSE into a a conventional degree program. This is typically based on misconceptions among the faculty of what CSE should be about. This talk will attempt to define a set of core skills that CSE programs should teach.

Undergraduate CSE: the SIAM report and research experiences for undergraduates. **Peter Turner** (Clarkson University, USA) IC/MT3456/015

This talk will begin with an introduction to the recently completed SIAM Working Group Report on Undergraduate Computational Science and Engineering. This report covers several aspects including program and course content, different types of undergraduate CSE programs and the desire for research experience within them. The report documents the rapid increase in interest in such undergraduate CSE programs, which can vary from complete baccalaureate majors, through minors or tracks, to just a few courses which can be included in other majors. One of the principal findings and recommendations was the encouragement of internships or other forms of professional or research experience as an important component. Such experiences are valuable in their own right in undergraduate education in general but have a particular role in helping our students understand at first hand the interplay among the various component disciplines that contribute to successful computational science or engineering projects.

IndustrySs need for computational scientists and engineers. **Kirk Jordan** (International Business Machines (IBM), USA) IC/MT3657/015

Computation plays ever increasing and vital role in industry in many scientific areas; from modeling of gas turbines for jet engines to decrease testing to biological models for heart disease to speed clinical trials. In industry, there is an increasing reliance on computational models and simulations. The need to for industry technical and managerial staff who understands computational science and engineering is increasing for companies to remain competitive in today's world. To emphasize this, I will briefly describe a few examples of industry's trend toward simulation and modeling. As this trend continues, industry will increasingly seek individuals with a computational science and engineering background. I will briefly describe what industry might be looking for when seeking to hire an individual with a computational science and engineering background. In closing, I will try to briefly describe how industry works and how to have an impact there.

IC/MP120/025: Level-set methods: current development and applications.

Organiser: Yen-Hsi Tsai (University of Texas at Austin, USA)
Co-organiser: Frédéric Gibou (UC Santa Barbara, USA)
Co-organiser: Stanley Osher (University of California, Los Angeles, USA)

Several problems that arise in science and engineering can be formulated as a front evolution between two (or more) phases. Examples include solidification problems, dendritic growth in materials science, free surface flows, and multiphase flows, to cite a few. One of the main the difficulties in solving such problems comes from the fact that the interface location must be computed as part of the solution to the underlying equations.

Since their inception, level set methods have been extremely successful in tackling these problems. In this minisymposium, the focus will be given to recent advances in the core level set algorithms as well as their applications. Specifically, the core algorithm will cover topics on adaptivity, volume conservation, and solving inverse problems. Applications will include multiphase flows, high frequency wave propagation and shape optimization.

This minisymposium will offer an excellent opportunity for researchers to learn about a wide variety of recent developments in the computational aspects of level set methods as well as their applications and will stimulate cross-pollination between disciplines.

Applications of implicit functions to finite volume discretizations of PDE. **Peter Schwartz** (Lawrence Berkeley National Laboratory, USA), Philip Colella (Lawrence Berkeley National Laboratory, USA) IC/MT3411/015

We address the problem of constructing implicit representations of propagating fronts in fluids. Our interest lies in coupling such representations to second order accurate volume of fluid discretizations of PDE with time-dependent boundaries. Here, we focus on two issues:

1. A discretization of the Hamilton–Jacobi PDE appropriate to interface tracking in fluids problems, which leads us to also consider second-order accurate methods for narrow band formulations of the eikonal equation.
2. An algorithm that uses implicit functions for calculating geometric data, second order in space and time, that can be coupled to second-order accurate discretizations of fluid equations on both sides of the zero level set.

A second-order accurate level-set method on non-graded adaptive Cartesian grids. **Chohong Min** (KyungHee University, Republic of Korea) IC/MT3645/025

We present a level set method on non-graded adaptive Cartesian grids; i.e., grids for which the ratio between adjacent cells is not constrained. We use quadtree and octree data structures to represent the grid and a simple algorithm to generate a mesh with the finest resolution at the interface. In particular, we present:

(1) a locally third-order accurate reinitialization scheme that transforms an arbitrary level-set function into a signed distance function;
(2) a second-order accurate semi-Lagrangian methods to evolve the linear level-set advection equation under an externally generated velocity field;
(3) a second-order accurate upwind method to evolve the non-

linear level-set equation under a normal velocity as well as to extrapolate scalar quantities across an interface in the normal direction; and
(4) a semi-implicit scheme to evolve the interface under mean curvature.

Combined, we obtain a level set method on adaptive Cartesian grids with a negligible amount of mass loss. We propose numerical examples in two and three spatial dimensions to demonstrate the accuracy of the method.

ENO schemes for adaptive grids. **Thomas Cecil** (University of Texas at Austin, USA) IC/MT3433/025

We introduce high order ENO schemes which can be applied on adaptive grids. These schemes are simple modifications of those used on uniform grids and can be applied to hyperbolic problems and Hamilton-Jacobi equations arising in level set flows.

Flexible Matlab implementation of the toolbox of level-set methods. **Ian Mitchell** (University of British Columbia, Canada) IC/MT4300/015

The Toolbox of Level Set Methods is a collection of Matlab routines providing high order accurate finite difference approximations on Cartesian grids in any number of dimensions, although computational cost and visualization make dimensions four and higher a challenge. The modular design of the toolbox makes it easy to try out new level set algorithms, as will be shown by the simple addition of a collection of explicit RK integrators and monotone approximations for degenerate second order spatial terms. We will also demonstrate how the toolbox permits quick and easy experiments with state of the art level set algorithms, and some of the extensive set of examples that are included with the software release. The toolbox and all of its source code is available from the author's web site.

IC/MP67/010: Computational science and engineering (CSE).

Organiser: Kaspar Nipp (ETH Zürich, Switzerland)
Co-organiser: Hans-Joachim Bungartz (TU München, Germany)
Co-organiser: Oskar von Stryk (TU Darmstadt, Germany)

Today, many problems in science and engineering can only be treated using computer-based modelling and simulation. Simulation permits studying complex systems which would be too expensive, dangerous or inaccessible to experiments. Computational Science and Engineering (CSE) is a rapidly growing interdisciplinary area connecting science, engineering, mathematics and computer science. However, CSE is different from traditional disciplines. It represents a third way which complements theory and experiment. CSE requires a dedicated educational process to be effective in research, both in academia and industry.

We plan to give an overview of experience and research in CSE with the goal of making this field better known to a broader community. European universities were among the first to establish CSE programs (e.g. KTH Stockholm, ETH Zürich, Erlangen). We want to provide an exchange of information between CSE curricula in Europe and elsewhere. Two CSE graduates will present research papers.

State-of-the-art and future research directions in computational electromagnetics. **Thomas Weiland** (TU Darmstadt, Germany) IC/MT2652/010

Computational Electromagnetics has become an integral part of virtually every design process in industry and research in almost every application area of electromagnetic fields. The reliability of todays software tools has grown to a stage which allows solving for larger and larger problems with 10**9 to 10**10 unknowns. With the shear size of these new classes of problems completely new classes of problems appear as well. Handling the plain input data set becomes a crucial issue. Geometrical object descriptions with 100.000 polygonal elements create a new complexity which can no longer be e treated by a person sitting at a screen inspecting the structure to be solved. Time domain simulations may create 10**12 to 10**14 double precision numbers as a typical result. Thus dedicated methods have to be developed for dealing with such massive amounts of data. The tremendous progress in research over the last three decades has created a large variety of reliable algorithms for very realistic applications. Today we are entering a transition period where there is a wide choice of possible algorithms for any given problem. Thus a methodology will be developed to automatically choose the most appropriate solution for a specific task.

Student Talk (15 mins.): *Comparison of hybrid methods for numerical prediction of aeroacoustic noise.* **Claudia Guenther** (RWTH Aachen, Germany), Michael Rom (RWTH Aachen, Germany), Thomas Gotzen (RWTH Aachen, Germany) IC/MT4784/140

In the recent years the emitted sound by aircraft has become a very contributing fact during the development process. Windtunnel experiments, however, are very expensive and so is also the direct computation of noise by solving full 3D Navier-Stokes equations.

The current study investigates various aspects of the hybrid approach via large-eddy simulation (LES) and different computational aeroacoustics (CAA) methods, such as the Ffowcs-Williams-Hawkings equation (FWH) with acoustic-pertubation-equations (APE).

That is, an interface between the LES and CAA solvers will be implemented to find an optimal balance for the three computational domains, the acoustic source region, the near field and the far field, in terms of computational efficiency and accuracy. A detailed analysis of spatial resolution of the acoustic source region and its impact on the acoustic field will be performed to acquire insight into the jet noise physics.

Student Talk (15 mins.): *Numerical simulations of fluid-structure-acoustic interactions to analyze human voice generation.* **Markus Gebhard** (Universität Erlangen-Nürnberg, Germany) IC/MT4914/140

After a larynx excision, as consequence of e.g., laryngeal cancer, the base of the human voice gets lost and a substitute voice is needed to communicate. A possible base of such a substitute voice represents the upper part of the esophagus, called the pharyngeal-esophageal (PE) segment. Via a valve, which the surgeon places between the esophagus and the trachea, the patient can guide air from the trachea into the esophagus. By virtue of that air stream the PE segment starts to vibrate and sound is generated, which can be used as base of a substitute voice. The future goal is to optimize the form of the PE-Segment, in order to ease and improve the artificial voice generation, by the use of simulations.

This substitute voice thereby consists out of three sources:

- the mechanical induced;

- the fluid mechanical induced; and
- the modulated sound sources.

The theoretical base of the stream-noise is represented by Lighthills analogy. Within the author's Master-thesis the research FEM-code CFS++ has been extended to fully coupled Fluid-Structure–Acoustic interactions in a single iterative staggered code.

Computational science education in the United States. **Michael Mascagni** (Florida State University, USA) IC/MT3845/140

We will examine several different types of computational science programs in the United States. We will give examples of undergraduate and graduate programs and attempt to classify the types of educational offerings currently available in the United States. At present many different types of US institutions are offering degree and non-degree programs in Computational Science. We will present examples of several types of these offerings.

CSE programs in Europe. **Lennart Edsberg** (Kungliga Tekniska högskolan, Sweden) IC/MT3278/010

In Europe CSE programs have been given for ten years. In 1997 the following three European universities offered Master programs in CSE: KTH (Stockholm), ETH (Zuerich) and University of Erlangen-Nuernberg. Since then there has been an increasing interest in this interdisciplinary science beacuse of its importance of making high performance computer simulations in e.g. fluid dynamics, electromagnetics, material science, quantum chemistry, molecular dynamics, biosciences, etc.

Today the number of European CSE programs has increased to more than 20 leading to a MSc and about 5 leading to BSc. It is desirable not only to start up more programs for the increasing demand of students with CSE education from applied sciences and industry. It is also important to initiate networks and other fora for presentation and exchange of teaching experience and successful curricula in this educational process.

In this talk an overview is given of the development of CSE programs in Europe so far. Examples of different syllabi and ways of organizing programs will be given as well as a discussion of further developing possibilities and improvements in the future.

IC/MP67/010: Computational science and engineering (CSE). #2

Organiser: Kaspar Nipp (ETH Zürich, Switzerland)
Co-organiser: Hans-Joachim Bungartz (TU München, Germany)
Co-organiser: Oskar von Stryk (TU Darmstadt, Germany)

(For abstract, see session #1 above.)

CSE/CE programs in Germany. **Oskar von Stryk** (TU Darmstadt, Germany) IC/MT2756/010

In recent years a remarkable number of cross-disciplinary study programs with graduate and undergraduate degrees in Computational Science and Engineering/Computational Engineering have been introduced at German universities. Similarities and differences in their curricula, educational goals and formal organization as well will be discussed. Conclusions on the further development on these programs will be drawn.

How to teach CSE?. **Hans-Joachim Bungartz** (TU München, Germany) IC/MT2996/010

Due to the interdisciplinary character of Computational Science and Engineering (CSE), each respective curriculum will contain contents and complete modules or courses from applied mathematics, informatics, and some field(s) of application such as physics or fluid mechanics. However, a serious education in CSE must go beyond a mere building block strategy. The CSE-specific core knowledge and skills to be imparted have to be identified, and innovative arrangements of topics as well as formats for courses are essential for a study program tailored to the needs of computational scientists and engineers in academia and industry.

This contribution will deal with some general educational aspects of study programs in CSE and report experiences with software group projects from the CSE master's program at TUM and from the Bavarian Graduate School of Computational Engineering, an honours program within the Elite Network of Bavaria.

Panel discussion (1 hour): *CSE has landed: who will give it a home and budget?.* **Kaspar Nipp** (ETH Zürich, Switzerland) IC/MT3763/140

In recent years, an increasing number of universities, especially those representing the engineering and natural sciences, have established study programs or research centers for CSE.

As a young and cross-disciplinary field, CSE needs special care and support concerning both research and education. After the different presentations, each focusing on a specific CSE-related aspect, the panel discussion concludes our minisymposium on CSE and, in particular, addresses the following questions:

- Why do we need CSE research and education?
- Should CSE education be implemented as a minor within existing related study programs (such as mathematics, computer science, physics, a classical engineering or science program) or should it be established as a major? If so, on a master's level only or also as an undergraduate program?
- Which departments are best suited to host CSE programs? Or do we need a new departmental structure (real or virtual) reflecting the cross-disciplinary character of CSE?
- The funding agencies are typically organized following the classical university subjects. Can this structure ensure an appropriate reviewing process and, hence, the funding CSE deserves and needs?

We expect a lively discussion and strongly encourage interaction with the audience.

IC/MP475/010: Computational science: teaching and textbooks.

Organiser: Gilbert Strang (Massachusetts Institute of Technology, USA)

An important responsibility of the computational science community is education of the next generation (and the present one!). This minisymposium will discuss essential goals in teaching scientists and engineers and mathematicians. In most cases their courses will combine science and algorithms and software—and we have work to do in finding the right combination and a successful approach.

The minisymposium is open to ideas from all participants at ICIAM.

Teaching computational science with computer algebra. **Walter Gander** (ETH Zürich, Switzerland) IC/MT3692/140

Modern powerful laptops equipped with a computer algebra system offer new ways to teach algorithms that are used in computational science. In this talk we discuss several examples. We show that by including computer algebra the students can concentrate more on fundamentals than on tedious details which sometimes obscure the goals.

Computer science for scientific computing. **G Stewart** (Univ. Maryland at College Park, USA) IC/MT3693/140

The AMSC program at the University of Maryland is an interdisciplinary program offering advanced degrees in applied mathematics and scientific computing. Most of our students have undergraduate degrees in mathematics, science, or engineering. Although these students are often fine programmers, few have had any systematic exposure to computer science. To remedy this lack, we have instituted a course that surveys topics in computer science: computer architecture, languages, compilers, run time environments, parallel computing, and networking. I have taught this course three times and am currently preparing a book "Computer Science for Scientific Computing" to support the course. In this talk I will share my teaching and writing experiences and perhaps draw a few conclusions.

A course in computational science and engineering. **Gilbert Strang** (Massachusetts Institute of Technology, USA) IC/MT487/010

Over the past 20 years we have developed a course that combines applied mathematics with scientific computing. Each lecture and each section of the text discusses a model problem and a code to solve it. The course is popular with engineering students and their departments who want exposure to ideas and also to software (especially MATLAB).

The main sections of the course are Applied Linear Algebra, Differential Equations, Finite Differences and Finite Elements, Fourier Methods, Analytical Methods, Large Sparse Systems, and Optimization. The starting point is to understand the second difference matrices that appear everywhere in scientific computing and simulation.

The need to move beyond the older courses in engineering mathematics, and make the connections with computing, is widely recognized. A pure software course misses the foundations for understanding new problems. The combination of analysis and computational engineering is powerful.

Lessons from Oxford's problem-solving squad. **Lloyd Trefethen** (University of Oxford, UK) IC/MT3691/140

In their first term, first-year DPhil students in Numerical Analysis at Oxford participate in the "Problem Solving Squad". Each week for six weeks, working in pairs, they tackle a computational problem whose answer is a single real number, and the aim is to find a solution numerically to high accuracy – ideally ten digits. I will mention some recent problems we have particularly enjoyed and comment on some lessons learned along the way.

IC/MP4330/010: Numerical computation using portable, extensible toolkit for scientific computation (PETSc).

Organiser: Hong Zhang (Argonne National Laboratory, USA)

Portable, Extensible Toolkit for Scientific Computation (PETSc) is a suite of data structures and routines for the scalable (parallel) solution of scientific applications modeled by partial differential equations. This minisymposium aims at the people engaged in algorithmic research and software development on large-scale numerical simulations. It provides opportunity for the current PETSc users to present their applications and their requirements for the future, as well as introduces potential users on how the software tools can be used to ease the difficulty and reduce the development time on their complex mathematical problems. This is also a good occasion for informal exchanges and discussions between users and developers of PETSc.

Future directions in PETSc. **Matthew Knepley** (Argonne National Laboratory, USA), Dmitry Karpeev (Argonne National Laboratory, USA) IC/MT4337/140

A major thrust of new PETSc development is the incorporation of a general framework for computational meshes and functions defined over them. Building on the Sieve abstraction for topology management, the new Mesh and Section classes allow unstructured mesh handling mirroring the existing DA class. We have also begun to integrate these into the DMMG multigrid framework. Example problems in PETSc will be shown and discussed.

Experiences on solving multi-physics problems with PETSc. **Xiao-Chuan Cai** (University of Colorado at Boulder, USA) IC/MT4338/140

Domain decomposition methods have been well studied for linear and nonlinear elliptic type problems. In this talk, we discuss some recent experimental work on using domain decomposition methods to some harder problems arising from multi-physics simulations, such as magnetodydrodynamics, boundary control of Navier-Stokes equations, and parameter identification problems. We present results based on a PETSc implementation of the Newton–Krylov–Schwarz methods and the focus is on the scalability of the methods when the number of processors is large.

Solving surface motion driven by surface diffusion with PETSc. **Wen Zhang** (Oakland University, USA), Ian Gladwell (Southern Methodist University, USA) IC/MT4341/140

We analyze the performance of the method of lines when solving a fourth order nonlinear partial differential equation with a moving boundary describing microstructural evolution of particles in a sintering process. Both the sequential ordinary differential equation solver and the corresponding parallel ordinary differential equation solver in PETSc are used in the study. We compare and discuss the performance and results.

Optimization of data-access delay. **Xian-He Sun** (Illinois Institute of Technology, USA) IC/MT4689/140

Although rapid advances in computing technology are bringing Petaflop systems within grasp, developing software on high end computers seems more elusive than that of ten years ago. The most significant question of computing remains the same today as it has been for decades: How can software applications take advantage of hardware computing power?

In this talk, I will describe the issues of performance evaluation, measurement, and optimization of high end systems, with a focus on sparse numerical computation. Existing metrics and methods will be summarized, and new challenges will be discussed. Particularly our recent results on reducing and masking data access delay will be presented, which includes the memory-LogP model for performance evaluation of advanced hierarchical memory system and the aggressive push-model methodology for data prefetching. Experimental results will be used to illustrate the practical impact of the current findings.

IC/MP4330/010: Numerical computation using portable, extensible toolkit for scientific computation (PETSc). #2

Organiser: Hong Zhang (Argonne National Laboratory, USA)

(For abstract, see session #1 above.)

Recent additions to PETSc, the scalable library for eigenvalue-problem computations. **José Román** (Universidad Politecnica de Valencia, Spain) IC/MT4349/140

SLEPc, the Scalable Library for Eigenvalue Problem Computations, is a software library for the solution of large, sparse eigenvalue problems on parallel computers. It can be used for the solution of problems formulated in either standard or generalized form, both Hermitian and non-Hermitian, with either real or complex arithmetic, as well as other related problems such as the singular value decomposition.

SLEPc focuses on sparse problems, for example, those arising after the discretization of partial differential equations. Several eigensolvers are available, such as Krylov–Schur, Lanczos, Arnoldi, Subspace Iteration and Power/RQI. SLEPc also provides built-in support for different types of problems and spectral transformations such as shift-and-invert or spectrum folding.

SLEPc is built on top of PETSc and extends it with all the functionality necessary for the solution of eigenvalue problems. This talk focuses on the features that have been added in the last year of development. The main additions are:

- A new eigensolver based on the Krylov–Schur method. This solver can be used for both symmetric and non-symmetric problems, and incorporates an effective restarting mechanism that makes it competitive with ARPACK.
- A new module for computing the truncated singular value decomposition (SVD) of a large sparse rectangular matrix, either via an eigensolver or by means of a specific algorithm such as Lanczos bidiagonalization.

SLEPc website: http://www.grycap.upv.es/slepc/.

Shift-and-invert parallel spectral transformations (SIPs) for solving eigenvalue problems. **Hong Zhang** (Argonne National Laboratory, USA) IC/MT4336/140

SIPs is a new efficient and robust software package implementing multiple shift-and-invert spectral transformations on parallel computers. Built on top of SLEPc and PETSc, it can compute very large numbers of eigenpairs for sparse symmetric generalized eigenvalue problems. The development of SIPs is motivated by applications in nanoscale materials modeling, in which the growing size of the matrices and the pathological eigenvalue distribution challenge the efficiency and robustness of the solver.

In this talk, I will present a parallel eigenvalue algorithm based on distributed spectrum slicing, describe the object-oriented design and implementation techniques in SIPs. As a PETSc developer, I will use this work as an example to illustrate how to efficiently develop special-purpose application code on the top of available parallel software packages.

Solving generalized complex-symmetric eigenvalue problems arising from resonant MEMS simulations with PETSc. **Tsuyoshi Koyama** (ETH Zürich, Switzerland), Sanjay Govindjee (ETH Zürich, Switzerland) IC/MT4832/140

In the operation of high frequency resonators in micro electromechanical systems(MEMS), there is a strong need to be able to accurately determine the energy loss rates or alternatively the quality of resonance. The resonance quality is directly related to a designers ability to assemble a high fidelity system response for signal filtering, for example. This has implications on robustness and quality of electronic communication and also strongly influences overall rates of power consumption in such devices - i.e. battery life. An index of the quality of resonance Q is inversely proportional to the amount of energy loss existing in the system, and can be defined in terms of the complex-valued eigenvalues ω of the system as, $Q = \frac{\mathrm{Abs}[\omega]}{\mathrm{Im}[\omega]}$. In this presentation, we examine methods for accurately simulating energy loss using the direct modeling of acoustic radiation via perfectly matched layer (PML) technology for 3-D structures, which results in complex-symmetric mass and stiffness matrices. Thus it is crucial that one is able to accurately compute eigenvalues of a complex-symmetric system. 3-D modeling increases the number of degrees of freedom and complexity in obtaining the solution, resulting in a requirement for more computing power and memory which can only be supplied by parallel computing methods. The simulations are conducted through the MEMS simulation software HiQLab in combination with the parallel numerical library PETSc. Different methods for preconditioning the iterative solution of linear systems of equations, a required step in the eigensolve, are pursued.

IC/MP123/145: Computational methods in astrophysics and cosmology.

Organiser: Wesley Petersen (ETH Zürich, Switzerland)
Co-organiser: George Lake (Universität Zürich, Switzerland)

Numerical simulations of N-body systems began with $O(N^2)$ methods which computed the force on particle j via

$$\mathbf{F}_j = G \sum_{i \neq j}^{N} m_j m_i (\mathbf{x}_j - \mathbf{x}_i)/|x_j - x_i|^3$$

which for millions of objects quickly became prohibitive computationally. In consequence, tree, particle-in-cell, and adaptive methods have been developed. Adding gas and other energy forms to the simulations requires more sophistication. In planetary system formation problems, a very large number of timesteps are also required. In this minisymposium, various techniques and computational experiences will be discussed.

Parallel Particle Based Simulations in Astrophysics. **George Lake** (Universität Zürich, Switzerland) IC/MT3969/145

I will describe the issue and methods that we use for problems from planet formation to cosmology. These are all spatially and temporally adaptive and based on particle methods. The range of codes are gravitation, SPH (Smooth Particle Hydro) and "rock/sand" dynamics with surface friction. Results will focus on the evolution of dark matter in the current cosmological model. We have used a variety of parallel machines over the years and are now getting interested in various accelerators from CELLs to GPUs.

Asymptotics of expanding cosmological models. **Alan Rendall** (Max-Planck-Institut Potsdam, Germany) IC/MT3973/145

Cosmology describes the universe on the largest scales which can be observed and there the dominant physical force is gravity. The appropriate description of gravity in this context is given by general relativity, where the Einstein equations are coupled to equations describing matter. The realization in the last decade that the expansion of the universe is accelerated has led to the consideration of exotic types of matter with negative pressure. This talk will describe mathematical results on the dynamics of solutions of the Einstein equations coupled to matter, conventional or exotic. In particular it will explain some of what is known about the asymptotics of a phase of unending cosmological expansion.

Stability of solutions to the Einstein equations: Cauchy problem for the Einstein vacuum equations with asymptotically-flat initial data. **Lydia Bieri** (ETH Zürich, Switzerland) IC/MT3990/145

Gravity within General Relativity (GR) is described by spacetime curvature. And the Einstein equations link the curvature of the spacetime to its matter content. For many physical situations, it is appropriate to study the Einstein equations in vacuum (EV). To describe isolated gravitating systems within GR, we consider asymptotically flat solutions of these equations. Examples for such isolated gravitating systems are binary stars, clusters of stars, galaxies etc. They all have in common, that they can be thought of as having an asymptotically flat region outside the support of the matter. This talk shall focus on the Cauchy problem for the EV equations and discuss asymptotically flat solutions of these equations. It will explain some completeness results in view of these solutions.

Numerical models for cosmic-ray modified hydrodynamics. **Francesco Miniati** (ETH Zürich, Switzerland) IC/MT4051/145

Astrophysical flows are commonly turbulent and supersonic, be it on planetary, galactic or cosmic scales. Dissipation mechanisms, particularly at shock waves, are regulated by particle wave interactions in addition to viscous effects, giving rise to populations of suprathermal (cosmic-rays) particles that are dynamically important. After discussing the microscopic issues involved in a correct solution of the problem, I will describe a numerical model, based on Glimm's method and a modified Riemann's solver, for a fluid system made of gas and cosmic-ray particles. I will present test results and discuss current issues and future developments of the presented method.

IC/MP123/145: Computational methods in astrophysics and cosmology. #2

Organiser: Wesley Petersen (ETH Zürich, Switzerland)
Co-organiser: George Lake (Universität Zürich, Switzerland)

(For abstract, see session #1 above.)

Supersonic turbulence in shock bound slabs . **Doris Folini** (ETH Zürich, Switzerland), Randall LeVeque (University of Washington, USA), Rolf Walder (ETH Zürich, Switzerland), Jean Favre (CSCS, Manno, Switzerland) IC/MT4085/145

Supersonic turbulence is a main agent for structure formation in space, from stellar winds to wind-blown bubbles, supernovae remnants, and the interstellar medium. Dissipation is mostly due to shocks. Under isothermal conditions, density is log-normally distributed, with a variance that grows with Mach number, the exact scaling of which is under debate. We discuss 2D and 3D numerical simulation of supersonic turbulence in plan-parallel slabs. We present scaling laws derived from dimensional analysis of the problem. Simulations provide scaling parameters, give a deeper insight into the dissipation mechanism, and provide high-order structure functions which are observable in space.

Low Mach-number models in computational astrophysics. **John Bell** (Lawrence Berkeley National Laboratory, USA) IC/MT4107/145

The early stages of a type-Ia supernova are characterized by long periods of convection leading up to ignition and propagation of deflagration waves. Both the convection and the deflagration waves are low Mach number flows. In this talk, we will introduce numerical models for the simulation of Type-Ia supernovae based on a low Mach number formulation. The low Mach number formulation analytically removes acoustic wave propagation while retaining the compressibility effects resulting from nuclear burning and ambient stratification. This formulation generalizes low Mach number models used in combustion that are based on an ideal gas approximation to arbitrary equations of state such as those describing the degenerate matter found in stellar material. The low Mach number formulation permits time steps that are controlled by the advective time scales resulting in a substantial improvement in computational efficiency compared to a compressible formulation. We will briefly discuss the basic discretization methodology for the low Mach number equations and their implementation in an adaptive projection framework. Computational results illustrating application of the methodology will be presented.

On the cusp of the dark matter. **Hugh Couchman** (McMaster University, Canada) IC/MT4211/145

The Lambda Cold Dark Matter model, now strongly constrained by direct observation at early epochs, successfully describes the structure of the evolved universe on large and intermediate scales. Among the significant problems is a persistent discrepancy between observations of nearby galaxies, which imply that galactic dark matter haloes have flat cores, and the cosmological model, which predicts that the halo should have a central density cusp. Using N-body simulations with star formation and feedback we show that random bulk gas motions in small primordial galaxies, of the magnitude expected in these systems, result in a flattening of the central dark matter cusp on short timescales. Gas bulk motions in early galaxies are driven by supernova explosions and stellar winds from ongoing star formation. During the subsequent evolution, most of the galactic gas will be consumed by star formation and lost via galactic winds, leaving a gas content in agreement with obser-

vations of present-day galaxies. The mechanism is general and would have operated in all star-forming galaxies at redshifts > 10. Once removed, the cusp cannot be reintroduced during the subsequent merger hierarchy involved in building larger galaxies. As a consequence, in the present universe both large and small galaxies would have flat dark matter core density profiles, in agreement with observations.

IC/MP687/015: Geometric-topological methods for 3D shape classification and matching.

Organiser: Michela Spagnuolo (Consiglio Nazionale delle Ricerche, Italy)

The volume and type of information made available via the web is increasing at an extraordinary speed and search engines have become the preferred interaction tools for engaging with this data deluge. In particular, search and retrieval of three-dimensional media will rapidly become a key issue in the upcoming panorama of multimedia content: 3D is indeed expected to represent a huge amount of traffic and data stored in the Internet. 3D media, or shapes, are digital representations of either physically existing objects or virtual objects that can be processed by computer applications and are primarily characterised by their form or spatial extent in the 3D space.

The problem of shape classification and matching is traditionally approached by finding effective abstract descriptions for shapes and by defining efficient methods to estimate the similarity among them, via the computation of some distance measure among descriptors.

In this context, the programme of minisymposium will provide an overview of recent advances in the area, focusing on descriptors as well as on methods to use them for retrieval and classification. The first part, more oriented towards shape descriptors, will cover approaches based on the exploitation of geometric properties as well as approaches oriented to the characterization of the shape topology, up to the very recent advances related to the use of eigenfunctions of the Laplace-Beltrami operator to characterize a shape in an intrinsic manner.

The second part, more oriented towards the use of descriptors to evaluate the similarity among shapes, will cover approaches based on partial and global graph-matching techniques and combinations of different techniques to support the classification process. An analysis of open problems and future perspectives will conclude the programme.

Laplacian eigenfunctions for shape matching. **Bruno Levy** (INRIA Lorraine, France) IC/MT2919/147

In 3D geometry processing, classifying and matching shapes is of paramount importance. With the advance of 3D scanning technology, it is now reasonably easy to create large geometric databases, as done for instance in the AIM@SHAPE European project (see http://shapes.aim-at-shape.net/index.php).

To make an efficient use of this data, classifying and matching meshes has became an important issue in geometry processing. In this context, one of the important problems concerns the matching between two different meshes representing the same object (or two objects with similar shapes).

To efficiently transfer informations (e.g. textures) between those two meshes (or to determine these two meshes as two instances of the same object), one needs to find shape descriptors that are independent on the discretization of the object.

Another way of thinking about the problem is to think in terms of coordinates and parameterization. In this talk, we investigate the use of Laplacian eigenfunctions to define such coordinates. In our talk, we will review the state of the art, and propose new directions of research.

Matching shape graphs. **Fatih Demirci** (Universiteit Utrecht, The Netherlands) IC/MT3396/147

With ever growing databases containing multimedia data, indexing has become a necessity to avoid a linear search. We propose a novel technique for indexing multimedia databases whose entries can be represented as graph structures.

In our method, the topological structure of a graph as well as that of its subgraphs are represented as vectors in which the components correspond to the sorted Laplacian eigenvalues of the graph or subgraphs. Instead of using the adjacency matrix for graph characterization as done in some earlier work, we characterize our graphs based on the Laplacian spectrum, which is more natural, more important, and more informative about the input graphs.

We draw from recently-developed techniques in the field of spectral integral variation to overcome the problem of computing the Laplacian spectrum for every subgraph individually. We will discuss techniques to reduce the cost we pay for computing such a signature.

Having established the signatures, the indexing now amounts to a nearest neighbor search in a model database. By doing such search around the query spectra, similar but not necessarily isomorphic graphs are retrieved. Given a query graph, a voting schema ranks database graphs into an indexing hypothesis to which a final matching process can be applied. The novelties of the proposed method come from the powerful representation of the graph topology and successfully adopting the concept of spectral integral variation in an indexing algorithm. To examine the fitness of the new indexing framework, we have performed a number of experiments using an extensive set of recognition trials in the domain of 2-D and 3-D shape recognition. The experiments, including a comparison with a competing indexing method using two different graph-based object representations, demonstrate both the robustness and efficacy of the overall approach.

Shape-matching and classification using structural descriptors. **Simone Marini** (Consiglio Nazionale delle Ricerche, Italy) IC/MT2503/147

Technological improvements related to object acquisition, visualization and modeling, have caused a considerable growth of the number of 3D models in digital form. Digital 3D models are now available in large databases of shapes, ranging from unstructured repositories, like the web, to specialized catalogues used in engineering and simulation. In this panorama it is clear that methods for the retrieval and automatic classification of 3D content will play a crucial role in the development of efficient applications for the organisation and filtering of 3D data.

The use of structural descriptors is an intermediate step between the geometry and the semantics of the object. Structural descriptors characterize features of the object that are relevant to the application context the matching process is focused on. Moreover information about the shape structure may make the difference when the sub-part analysis supports the automatic classification and/or retrieval processes.

Starting from these remarks, the application of a methodology based on the coupling of geometric and structural information will be discussed for the global and partial matching of 3D shapes and for their automatic calssification.

Future perspectives in shape classification and matching: the role of semantics in similarity assessment. **Bianca Falcidieno** (Consiglio Nazionale delle Ricerche, Italy) IC/MT2531/147

It is quite evident that reasoning about shapes naturally leads to refer to resemblance, similarity, or equivalence concepts, which are the basis for shape description and retrieval. Current approaches to these problems involve complicate geometric comparisons and, despite the recent improvements, all development has focused on geometry, which provides a complete description of the (geometric) shape of a solid. The choice of a mathematical model is mainly determined by a set of restrictive computational requirements such as representational finiteness, constructivity and completeness, which are related to the properties of the mathematical model.

But it also should consider other constraints imposed by downstream applications. When we want to portray the complexity of nature or intricate man-made objects, traditional geometric entities are unable to do so in a manageable and controllable fashion. The result is that information related to the meaning or function of an object is something *attached* to its geometry if not an alternative to it. Current systems are unable to measure similarity according to criteria relevant for specific application domains, such as manufacturing or product modelling. Therefore, it is important to develop ways to measure similarity among shapes, that can tell us how similar or different they are in a specific context and that reflect those notions of similarity useful in the application context in which it has to be used.

In this scenario, it is interesting and challanging to reformulate the traditional modelling paradigm by formalising the concept of *meaning*, through the definition of a semantic universe in addition to the physical one. This means building a conceptual model of the application domain based on a set of fundamental classes or types. In addition to the physical universe related to the real or virtual world, a semantic universe could be defined for representing human knowledge of a particular domain.

IC/MP687/015: Geometric-topological methods for 3D shape classification and matching. #2

Organiser: Michela Spagnuolo (Consiglio Nazionale delle Ricerche, Italy)

(For abstract, see session #1 above.)

Mathematical tools for shape classification and matching. **Michela Spagnuolo** (Consiglio Nazionale delle Ricerche, Italy) IC/MT2038/147

While information is moving from textual to visual form, supported by emerging technologies, *digital shapes* are becoming more and more important. Digital shapes populate virtual environments in advanced scientific simulation as well as in emerging edutainment applications.

Due to the recent improvements the acquisition, visualization and modeling technologies, the number of 3D shapes available on the web is more and more growing, and there is an increasing demand for tools supporting the automatic search for 3D objects and their sub-parts in digital archives.

Assessing the similarity among 3D shapes is a very complex and challenging research topic. While human perception have been widely studied and produced theories that received a large consensus, the computational aspects of 3D shape retrieval and matching have been only recently addressed.

This has also caused a gradual shift of research interests from methods to represent shapes towards methods to *describe* shapes in Computer Graphics as well. This has led to a rapidly increasing number of methods and tools addressing the same basic issues targeted by Computer Vision, that is, segmentation, recognition and understanding. While a digital model, either pixel- or vector-based, is a digital representation which is quantitatively similar to an object, its description is only qualitatively similar.

Shape analysis and understanding are therefore basic tools for constructing object descriptions, necessary to answer problems arising in the many applications which deal with digital shapes.

Differential topology methods for shape description. **Silvia Biasotti** (Consiglio Nazionale delle Ricerche, Italy), Daniela Giorgi (Consiglio Nazionale delle Ricerche, Italy), Giuseppe Patanè (Consiglio Nazionale delle Ricerche, Italy) IC/MT2443/147

Differential topology, and specifically Morse theory, provides a suitable setting for formalizing and solving several problems related to shapes analysis. The fundamental idea behind Morse theory is that of combining the topological exploration of a shape with quantitative measurement of geometrical properties provided by a real function defined on the shape.

Several functions (e.g. harmonic fields and laplacian eigenfunctions) have been studied in contexts such as shape abstraction, parameterization, and comparison. Each of them gives a measure of specific properties of the input shape, playing the role of the *lens* through which we look at the properties of the shape. To compare the information provided by these functions, we analyse methods which use the configuration of isocontours and critical points for encoding 3D shapes, e. g. Reeb graphs.

Geometrical shape comparison by size theory. **Patrizio Frosini** (Università di Bologna, Italy) IC/MT2565/147

Size Theory allows us to compare shapes of topological spaces and manifolds with respect to properties described by real functions. The main tools used in Size Theory are some pseudodistances measuring the minimal changes of these real functions under the action of homeomorphisms. This leads to considering *size pairs* (S, f), where S is a topological space and f is a continuous *measuring function* with real values. For example, the different "bumpiness" of two closed surfaces X, Y in the Euclidean space can be compared by considering two manifolds $S(X) := X \times X$, $S(Y) := Y \times Y$ and taking the functions defined by setting $f_X(P_1, P_2) = -\|P_1 - P_2\|^2$, $f_Y(Q_1, Q_2) = -\|Q_1 - Q_2\|^2$.

When two shapes must be compared according to a new comparison criterion, the first step is to find the "right" set of corresponding properties, i.e. of size pairs $(S(X), f_X)$, $(S(Y), f_Y)$. The next step in the comparison process is to consider the *natural pseudo-distance*

$$d((S(X), f_X), (S(Y), f_Y)) := \inf_{h \in H} \sup_{P \in S(X)} |f_X(P) - f_Y(h(P))|,$$

where h varies in the set H of all homeomorphisms between $S(X)$ and $S(Y)$.

In this way, two objects are judged to be sharing the same shape if and only if they share the same shape properties; i.e., the natural pseudo-distance between the associated size pairs vanishes. This method can be adapted to several different definitions of shape without changing its geometrical-topological framework. Some new results about this approach to shape comparison are illustrated.

Deformation invariant 3D model descriptors. **Dietmar Saupe** (Universität Konstanz, Germany) IC/MT3814/147

In content-based 3D model retrieval the most commonly adopted approach is based on feature vectors that capture characteristics of corresponding surfaces. A suitable metric in feature vector space allows searching for the nearest neighbors of a query object. The feature vectors are typically designed with the goal of invariance with respect to scale and rigid object motion. However, in applications one may also wish to retrieve objects similar to the query object allowing certain nonlinear deformations. For example, one my wish to find objects with the same topological structure, that may be given by a graph connecting critical points of a suitable Morse function on the surface. Alternatively, one has considered invariance with respect to isometric transformations, i.e., deformations that do not stretch or tear the surface. In this presentation we briefly survey the approaches for 3D object retrieval with topological and bending invariance. A problem with the retrieval of isometric surfaces is the inherent complexity of the search that boils down to general graph matching known to be NP-hard. In our work we propose a statistical descriptor that provides a faster match but may not provide the optimal match between given surfaces. This work was carried out jointly with Mauro Ruggeri.

IC/MP727/015: Level-set methods: fluid applications.

Organiser: Yen-Hsi Tsai (University of Texas at Austin, USA)
Co-organiser: Frédéric Gibou (UC Santa Barbara, USA)
Co-organiser: Stanley Osher (University of California, Los Angeles, USA)

Several problems that arise in science and engineering can be formulated as a front evolution between two (or more) phases. Examples include solidification problems, dendritic growth in materials science, free surface flows, multiphase flows, to cite a few. One of the main the difficulties in solving such problems comes from the fact that the interface location must be computed as part of the solution to the underlying equations. Since their inception, level set methods have been extremely successful in tackling these problems. In this minisymposium, the focus will be given In this minisymposium the focus will be given to recent advances in the core level set algorithms as well as their applications. Specifically, the core algorithm will cover topics on adaptivity, volume conservation, and solving inverse problems. Applications will include multiphase flows, high frequency wave propagation and shape optimization. This minisymposium will offer an excellent opportunity for researchers to learn about a wide variety of recent developments in the computational aspects of level set methods as well as their applications and will stimulate cross-pollination between disciplines.

A new stability condition for surface tension-driven flows. **Paul Vigneaux** (Université de Bordeaux, France), Cédric Galusinski (Université du Sud-Toulon-Var, France) IC/MT4313/015

We consider models for the simulation of curvature-driven incompressible bifluid flows, where the surface tension term is discretized explicitly. Since Brackbill, Kothe and Zemach (J. Comput. Phys. 100, pp 335-354, 1992) introduced the Continuum Surface Force (CSF) method, many methods involved in interface tracking or capturing are based on this reference work. Particularly, the surface tension term is discretized explicitly and therefore, a stability condition is induced on the computational time step. This constraint on the time step allows the containment of the amplification of capillary waves along the interface, which can be the source of parasitic currents on the interface. The derivation of this stability condition puts more emphasis on the terms linked with the density in the Navier-Stokes equation (i. e. unsteady and inertia terms) rather than on the viscous terms. Indeed, the viscosity does not appear, as a parameter in this stability condition.

In this talk, we propose a new stability condition for which we present a theoretical estimation for flows with low and medium Reynolds numbers. We detail the analysis which is based on a perturbation study - with capillary wave - for which we use energy estimate on the induced perturbed velocity. This stability condition involves the fluid viscosity, emphasizing the role of viscous terms for such flows. We validate and illustrate our analysis with numerical simulations of microfluidic flows using a Level Set method. Finally, we propose a method to reduce computational cost induced by this stability condition for low flow velocities. This method still uses an explicit discretization of the surface tension term and takes advantage, as far as possible, of the stationary behaviour of the interface. This approach was inspired by the simulation of microflows applications which involve the exploration of different mixing regimes inside microdroplets.

Stability of flows in microfluidics. **Thierry Colin** (INRIA Futur Bordeaux, IMB, France) IC/MT4314/015

The aim of this talk is to present some results for interfacial flows in microfluidics. Flows in microfluidics are characterized by low Reynolds numbers and a by the fact that surface tension has a predominant role in stability issues. Jet or co-flows are special configurations that are of great importance for applications. The problem of their stability is therefore central in the understanding of experiments. Our goal is to characterize the stability of a jet of a newtonian fluid into another one when the effects of surface tension and confinement have competitive effects.

We have two different approaches: the first one is to compute directly the solution in a T-junction by a level-set method. This is done in 2-D, 2-D axi and 3-D. The second approach is a numerical spectral analysis: we first linearize the bi-fluids Navier–Stokes equation with free interface and surface tension around a steady-state solution. We then compute numerically the eigenvalues of the linearized operators. The sign of the real part of the eigenvalue gives the stability issue. Moreover, in the case of instability, the wavelength corresponding the the more unstable modes is related to the size of the droplets that are created. We investigate for which regime the jet is stable and we compare the size of the droplets that are created with experimental data.

This is a joint work with C.-H. Bruneau, A. Colin, C. Galusinski, S. Tancogne and P. Vigneaux.

Level-set simulation of solute/solvent interfaces. **Li-Tien Cheng** (University of California, San Diego, USA) IC/MT4138/025

The level-set method of Osher and Sethian for handling interfaces has sparked wide interest in numerous applications, ranging from fluid dynamics to image processing, since its creation. We consider here a level set method with a complicated geometric flow for construction of solute/solvent interfaces.

Investigating spontaneous capillarity-controlled events via the level set method. **Maša Prodanović** (University of Texas at Austin, USA), Steven Bryant (University of Texas at Austin, USA) IC/MT3216/015

An accurate description of the mechanics of pore level displacement of immiscible fluids could significantly improve the macroscopic parameter predictions from pore network models in real porous media. Assuming quasi-static displacement, we describe a simple but robust model based on the level set method for determining critical events for throat drainage and pore imbibition. The method arrives at geometrically correct interfaces while robustly handling topology changes and is independent of the pore space complexity.

An interface capturing method for two-phase flow with moving contact lines. **Gunilla Kreiss** (Uppsala University, Sweden) IC/MT2883/025

To begin with we discuss a new conservative level set method for immiscible two-phase flow, where each phase is governed by the incompressible Navier-Stokes equation, and the interface is advected with the local velocity. The method is conservative in the following sense: there is a small error in the mass of each the two phases due to the discretization error, but it does not grow over time. In a straightforward application of the method, a no-slip condition is imposed at a solid wall. Thus the resulting model cannot capture contact line dynamics. Inspired by a phasefield method based on Cahn-Hilliard theory for diffuse interfaces, we propose an extended model, which is capable of capturing a moving contact line. This work has been done in collaboration with Elin Olsson, Sara Zahedi, Walter Villanueva and Gustav Amberg.

A field-space-based level-set method for computing multi-valued solutions to Euler–Poisson equations. **Hailiang Liu** (Iowa State University, USA) IC/MT3854/015

We present a field space based level set method for computing multi-valued solutions to one-dimensional Euler–Poisson equations. The system of these equations has many applications, and in particular arises in semiclassical approximations of the Schrödinger-Poisson equation. The proposed approach involves an implicit Eulerian formulation in an augmented space — called field space, which incorporates both velocity and electric fields into the configuration. Both velocity and electric fields are captured through common zeros of two level set functions, which are governed by a field transport equation. Simultaneously we obtain a weighted density f by solving again the field transport equation but with initial density as starting data. The averaged density is then resolved by the integration of the obtained f against the Dirac delta-function of two level set functions in the field space. Moreover, we prove that such obtained averaged density is simply a linear superposition of all multi-valued densities; and the averaged field quantities are weighted superposition of corresponding multi-valued ones. Computational results are presented and compared with some exact solutions which demonstrate the effectiveness of the proposed method.

Solving PDEs on moving interfaces with applications to two-phase flow with surfactants. **Hongkai Zhao** (University of California, Irvine, USA) IC/MT2578/015

I will present an Eulerian formulation for solving PDEs on moving interfaces. In particular we give a decomposition of the surface Laplacian operator which allows us to design a semi-implicit scheme to overcome the stiffness of surface Laplacian operator. Applications to two phase flow with the effects of surfactants will be shown. This is a joint work with J. Xu, Z. Li and J. Lowengrub.

Accurate computation of interfacial, axi-symmetric Stokes flows. **Hector Ceniceros** (University of California, Santa Barbara, USA) IC/MT2771/015

Boundary integral methods have been used widely for the simulation of interfacial Stokes flows. These free surface representations reduce the problem to one defined solely on the fluid interface. However, it is difficult to obtain high order approximations to the resulting line integrals due to their singular nature and intricate structure. Existing quadrature rules for numerical integration of the interfacial velocity are, at best, of a limited second order accuracy. In this work, we analyze the problem of attaining higher order quadratures and propose new numerical approaches to overcome all the difficulties. These approaches are based on an application of analytic and local error corrections constructed from an asymptotic analysis of the integrands. We present quadratures that achieve a uniform accuracy of up to order five and demonstrate their superior accuracy with numerical examples. This is joint work with Monika Nitsche and Aino Karniala.

Bugs, errors, and unexpected results in computer-algebra packages. **Walter Krämer** (Bergische Universität Wuppertal, Germany) IC/CT2336/010

The following is a citation from the Description and aims of of the Dagstuhl Seminar on Algebraic and Numerical Algorithms and Computer-assisted Proofs:

"In contrast, most algorithms in computer algebra are 'never failing', that is they are proved to provide a solution for any input, and the maximum computing time for this is estimated *a priori*.

The focus of the talk will be the reliablity of the computer algebra system Maple. We will show that 'never failing' algorithms may be the theory but concerning actual implementations such a statement seems not to be drawn from life.

Simulation and solution of stochastic systems with a component-based software design. **Martin Krosche** (TU Braunschweig, Germany), Martin Hautefeuille (TU Braunschweig, Germany) IC/CT2435/015

Often uncertainties occur in the numerical simulation of real-world problems. A useful method is stochastic modelling. In this context Monte Carlo (MC) methods and the stochastic Galerkin method are well known and frequently used.

In the field of component-based software systems a component can be seen as an independant software or as a part of a software system. A corresponding architecture allows clearness, flexibility and reusability. The *Component Template Library* (CTL) is a so called middleware to realise component-based software systems, and fits to the requirements of scientific computing.

In this paper we present the design of a software system for the stochastic simulation using MC and stochastic Galerkin methods based on the CTL. For each Stochastic method a number of components are realised to allow parallel features.

Probabilistic model of fuzzy subsets. **Magda Tsintsadze** (Tbilisi State University, Georgia), Tamaz Gachechiladze (Tbilisi State University, Georgia) IC/CT497/015

It's known that except of stochastic uncertainty exists uncertainties of other types, there is an opportunity to expand an area of use for differential equations even in those cases when parameters determining differential equations contain uncertainty of new types and therefore there is no opportunity to pose the classical problem - We are offering modeling of these situations with help of new concept - canonically conjugated fuzzy subset.keywords:Fuzzy sets, Fuzzy Differential Equations, Optimal Membership Functions.

Graphical simulation of a new concept of low sized surgical parallel robot for camera guidance in minimally invasive surgery. **Calin Vaida** (Universitatea Tehnicã Cluj-Napoca, Romania), Doina Liana Pisla (Universitatea Tehnicã Cluj-Napoca, Romania), Nicolae Plitea (Universitatea Tehnicã Cluj-Napoca, Romania) IC/CT811/015

Surgery is one of the fields where robots have been introduced due to their positioning accuracy which exceed the human capabilities. This provided a cure for impossible to treat diseases, but introduced also several drawbacks: high space occupied in the operating room, lack of haptic feedback, extensive training and very high costs. Following a thorough analysis of existing market solutions, the paper presents the graphical simulation of a new concept of modular parallel robot for camera guidance in minimally invasive surgery with several improvements: small occupied volume, a very cheap structure, high reliability, reduced play and a small working volume. In surgery the robot capabilities should not exceed the volume requirements of the operating field, as an erroneous command or an error in the software could cause serious injuries for both patient and medical personnel. A complex simulation program was developed in order to study the geometric, kinematic and dynamic characteristics of parallel robots used for minimally invasive surgery. The facilities of the new achieved simulation software enable the possibility to develop a complex study about the kinematics and dynamics in order to optimize the parallel structure. The simulator is interactively achieved such as the user could influence the simulation parameters and could be informed about the possible errors during the simulation process. This simulation system was conceived to diminish the costs, to reduce the processing time, to optimize the use of the resources during the process implementation or process redesign and to assist specialists for the investments planning. The higher stiffness of the structure used for surgery will ensure a clear and stable image in any extreme position of the robot and the smaller manufacturing costs will make it affordable for a larger number of hospitals and usable in a wider range of interventions allowing more surgeons to get familiar with it.

Optimally scaling particle simulation method using multigrid. **Matthias Bolten** (FZ Jülich, Germany), Godehard Sutmann (FZ Jülich, Germany) IC/CT4798/015

Particle simulation methods are an important tool in different fields of research, e.g. in biophysics or plasma physics. These methods differ in working either directly on the particles or on a meshed representation. Multigrid methods are especially appropriate for the latter and they have been used in different algorithmic implementations. In particle simulation codes based on discrete spacial meshes usually the potential is split into a long-ranged and a short-ranged part. We recently introduced a method using charge-centered B-spline densities for the splitting by rewriting the right hand side of the PDE. As these densities are finitely supported, the resulting complexity is optimal, i.e. of order $\mathcal{O}(N)$. In order to achieve high accuracy, it is favorable to use B-spline densities with large support, even when high-order discretization is used for the solution of the PDE. As a result of this, the resulting complexity is still $\mathcal{O}(N)$, but the prefactor is rather large. Since the splitting formulation results in a convolution of the singular point charges with the B-spline density, Fourier-techniques can be used to sample the point charge replacing densities on the grid. This can be performed most efficiently with a nonequispaced FFT (NFFT), resulting in a large reduction of the prefactor.

In this talk we will present the complete method, which is based on a multigrid solver and which incorporates the NFFT to optimize the preparation step.

IC/CTS4646/14: Chemistry and heat conduction.

Newton–Krylov methods for fully coupling chemistry and transport. **Laila Amir** (INRIA Rocquencourt, France), Michel Kern (INRIA Rocquencourt, France) IC/CT2299/010

Modelling reactive transport in porous media, using a local chemical equilibrium assumption leads to a system of advection-diffusion PDE's coupled with algebraic equations. When several species are transported by a subsurface flow, one of the chemical phenomena involved is sorption, the process by which species may interact with the porous matrix, and become attached to the rock. Solving the chemical equilibrium problem keeps track of how much of the species remain mobile, and how much is fixed.

When solving this coupled system, the algebric equations have to be solved at each grid point for each chemical species and at each time step. This leads to a huge coupled non-linear system.

In this talk, we review different formulations of the coupled reactive transport problem, and we compare a formulation of a proposed global approach with the more tradional operator splitting approach that consists in solving separately the chemical equations and the transport equations. The method is formulated in terms of total mobile and total immobile concentrations. Its main advantage is to keep chemistry distinct from the transport equations, contrary to the more traditional direct substitution approach.

For any realistic configuration, it is not possible to form and store the Jacobian matrix. A better approach is to use Newton-Krylov methods, in which the Jacobian vector product calculated within an iterative Krylov solver may be approximated

instead of being computed with an explicit Jacobian. The product is simply approximated by finite differencing the residual equation in the direction of the Krylov vector.

A critical ingredient needed for the success of a Jacobian-free Newton method is efficient matrix-free preconditioning, since the Jacobian is never computed explicitly. For this purpose, we use an operator-splitting preconditioning which is known to be a good preconditioning technique for this kind of problem.

A regularization approach for surface reconstruction. **Hebert Montegranario** (Universidad de Antioquia, Colombia) IC/CT621/010

Ill-posed inverse problems arise in many branches of science and engineering. In the typical situation one is interested in recovering a whole function given a finite number of noisy measurements on functionals. A regularization approach is one of the solutions for this kind of problem among which we find surface reconstruction from point clouds. In this talk we present a classification of methods for surface reconstruction and its solution in the framework of classical regularization, that is, in terms of linear combinations of the reproducing kernel in certain proper spaces for reconstruction. We evaluate the quality of this solution to approximate 3D data and some examples for computational implementation are also shown in order to complete a user's guide for an efficient employment of kernel methods in the reconstruction of multivariate functions.

Solving multi-subdomains problem in certain nonlinear heat-conduction process. **Antony Siahaan** (University of Greenwich, UK), Choi-Hong Lai (University of Greenwich, UK), Koulis Pericleous (University of Greenwich, UK) IC/CT2471/015

Some coupling techniques for nonoverlapping domain decomposition method are investigated in this paper. We test these methods on some linear and nonlinear heat conduction processes taking place in a multi-chip module which has many geometrically structured subdomains. The problem of interface condition between two adjacent subdomains is tackled by incorporating a defect equation which is solved iteratively. We evaluate two defect equations on this scheme, i.e. the difference of normal derivative and the residual of discretized heat conduction equation itself. Both equations lead to systems of nonlinear equations which are solved by means of quasi-Newton methods with an adaptive alpha rate instead of a Jacobian matrix. The simulation suggests that the second defect equation is much more accurate. The present scheme is also compared with the scheme that uses the Conjugate Gradient method as the nonlinear solver.

Deterministic sensitivity analysis for a model for flow and transport in porous media. **Estelle Marchand** (INRIA Rocquencourt, France), François Clément (INRIA Rocquencourt, France), Jean Roberts (INRIA Rocquencourt, France), Guillaume Pépin (ANDRA, France), Laurent Loth (ANDRA, France) IC/CT2288/010

The questions of safety and uncertainties are central to feasibility studies for an underground nuclear waste storage site. Uncertainties concerning safety indicators, such as the water flow through outlet channels or the concentrations of contaminants, which are due to uncertainties concerning properties of the subsoil or of the contaminants, must be evaluated.

Probabilistic methods can be used. They give good results and are relatively easy to implement, but they are expensive because they require a large number of simulations. The deterministic methods investigated here are much less demanding in computing time but they give only local information. Thus the two methods are complementary and both deserve to be developed.

The deterministic method used here is based on the singular value decomposition of the Jacobian matrix of the mathematical model of the problem, which consists of a flow equation based on the stationary Darcy law, a transport equation, ie a mass balance equation, for each contaminant, and a law of exchange between liquid and solid phases for each contaminant.

The first step is the computation of the derivatives of the mathematical model. For the flow equation we use a code differentiated through analytical formulas, using the adjoint state method. For the transport equation we combine manual differentiation and automatic differentiation with the library AdolC.

The singular value decomposition provides a hierarchical list of directions in both the space of input parameters and in the space of safety indicators.

For the flow model, various deterministic studies have been computed for a 3 dimensional test case. We observe a weak variability of the local sensitivities when the choice of the input parameters varies in the spectrum of possible input parameters. Probabilistic and deterministic studies provide similar results. We also compare results obtained through a probabilistic and a deterministic analysis for the full model.

COOL: constraints-oriented library. **Ralf Gruber** (École Polytechnique Fédérale de Lausanne, Switzerland), Mejdi Azaiez (Ecole Nationale Supérieure de Bordeaux, France) IC/CT1216/010

The new partial differential equation solver COOL is presented. The solver exactly satisfies external and internal constraints such as $\vec{\nabla}\cdot\vec{u} = 0$ (Stokes, incompressible Navier–Stokes), $\vec{\nabla}\cdot\vec{B} = 0$ (Maxwell), or $\vec{\nabla}\times\vec{E} = 0$(plasma waves). The method is presented by means of the two dimensional Stokes eigenvalue problem in the unit square Ω=$[-1,+1]^2$: *Find* $\vec{u_h} \in \mathbf{X_h}$ *and* $\omega^2 \in \mathbb{R}^+$ *such that*

$$S(\vec{u_h},\vec{v_h}) := \int_\Omega \vec{\nabla}\vec{u_h}\cdot\vec{\nabla}\vec{v_h}\mathrm{d}\mathbf{x} = \omega^2 \int_\Omega \vec{u_h}\cdot\vec{v_h}\, d\mathbf{x},\ \forall \vec{v_h} \in \mathbf{X_h},$$

$$mathbfX_h = \{\vec{v_h}\ ,\ \vec{\nabla}\cdot\vec{v_h} = 0\ ,\ \vec{v_h} = 0 \text{ for } \vec{x} \in \partial\Omega\}.$$

This problem is solved in two steps applying a new constraints oriented non-conforming hp method in which all the terms appearing in the variational formulation have the same functional dependence in each element and the same regularities accross element borders. For this purpose, two canonical polynomial basis functions are defined

$$h_j(x) = -\frac{1}{p(p+1)}\frac{1}{L_p(\xi_j)}\frac{(1-x^2)\,L_p'(x)}{(x-\xi_j)}, \qquad -1 \le x \le +1, \tag{1}$$

$$g_j(x) = h_j(x) - \frac{L_p(x)}{(p+1)L_p(\xi_j)}, \qquad 0 \le j \le p\ ,$$

where L_p is the Legendre polynomial of degree p, L_p' its derivative, and ξ_j, $j = 0,1,..,p$, are the zeros of $(1-x^2)L_p'(x) = 0$. Since $L_p(x)$ is zero at the Gauss points ζ_i, $i = 1,..,p$, $h_j(\zeta_i) = g_j(\zeta_i)$. The function $h_j(x)$ is a polynomial of degree p, continuous accross element borders. It is used to represent partial derivatives that become polynomials of degree $p-1$, discontinuous accross element borders. The function $g_j(x)$ is a polynomial of degree $p-1$, discontinuous accross element borders. It is used to represent terms without deriva-

tives. As a consequence, each term in the variational form and in the $\vec{\nabla}\cdot\vec{u}$ term are polynomials of degree $p-1$ in x and y, discontinuous accross element borders. As a consequence, $\vec{\nabla}\cdot\vec{u}\equiv 0$ can be satisfied. In the first step, $\vec{\nabla}\cdot\vec{u}=0$ is imposed at the Gauss points, leading to algebraic conditions between the old ($\vec{u}$, two components) and the new dependent variables ($\vec{z}$, one component) that remain after elimination of $\vec{\nabla}\cdot\vec{u}=0$. In matrix form these conditions write $\vec{u}=M\vec{z}$. The initial eigenvalue problem $A\vec{u}=\omega^2 B\vec{u}$, issue of eq.(1) then becomes $M^TAM\vec{z}=\omega^2 M^TBM\vec{z}$. The eigensolution of the 2D Stokes spectrum converges exponentially as in conforming hp methods. Only Stokes modes are obtained. The $\vec{\nabla}\cdot\vec{u}=0$ is exactly satisfied. The condition number of the M^TAM matrix is smaller than for a Poisson equation. The matrix M is sparse. Thus, this COOL method is perfect to be applied to time evolutionary problems that are constraint by side conditions such as incompressible Navier–Stokes, or Maxwell's equation.

Finite-volume simulation of inundation due to tsunamis. **Stephen Roberts** (Australian National University) IC/CT2832/144

Hydrodynamic modelling allows flooding, storm-surge and tsunami hazards to be better understood, their impacts to be anticipated and, with appropriate planning, their effects to be mitigated. Geoscience Australia in collaboration with the Mathematical Sciences Institute, Australian National University, is developing a software application called AnuGA, based on the Finite Volume method to model the hydrodynamics of floods, storm surges and tsunami.

In this talk we will describe the computational model used in AnuGA, provide validation of the method using a standard benchmark, and provide the results of a tsunami simulation of the coastal region of north eastern Australia, near the city of Cairns.

Numerical simulation of building evacuation in emergency conditions. **Alicia Guadalupe Ortega Camarena** (TU Braunschweig, Germany) IC/CT2467/015

One of the main contributing factors for human safety regarding on buildings with people inside, is the effective possibility of evacuation after a disaster has occurred. In this sense, different models of human crowds have been developed in order to simulate the behaviour of pedestrians once an emergency condition has occured, and the evacuation of the building is necessary. Simulation models have been conceived from two different perspectives: 1) the psychological scope, and 2) the engineering scope.

Up to now, the two main approaches from the engineering perspective are given by the macroscopic and the microscopic models. One of the first macroscopic-based models are those which approximate the pedestrian movement as a gas or fluid or with particle dynamics, where lattice-Boltzman models, Navier-Stokes traffic-like equations, and H-theorem are the most representatives ones. In the other hand, microscopic-based models take into account the individual characterisitics of the pedestrians, and the crowd-elements are not generalized as it occures in the macroscopic approach. The most representative models are the social force model, and the models based on driving forces created by potential or static/dynamic fields created by the same pedestrians on their way to the emergency exit. For these models the development and the use of cellular automata is frequent. A third new appearing approach is given by the mesoscopic model, which can be seen as an hybrid technique that involves elements of both macro- and micro-scopic approaches, and evenmore some other elements like the virtual reality are also here integrated.

In the psychological perspective, models have been defined by mainly three different concepts: a) what do people see, b) what do people want, and c) what do people perceive from the environment before, during and after an evacuation in an emergency condition. But less in this field has been explored, because of many factors like "lack of knowledge", the almost rare or inexistent information of pedestrian evacuations in real scenarios, which makes the psychological models more vague and intagible.

One of the main objectives in this research is the integration of psychological elements of human behaviour during evacuation, and specially those related to the apparison of panic into our proposed model. Obtaining in this case a more realistic approach of crowd movements during emergency evacuations which later can be used for the evaluation of the influence in the behaviour and dynamics of pedestrians by means of possible physical blockages in the real scenario (e.g. doors, stairs, corridors), and with this to minimize the overall risk of the occupants.

Locally one-directional finite-volume schemes on cubed sphere. **Ramaz Botchorishvili** (Tbilisi State University, Georgia) IC/CT3530/014

An approach for constructing numerical schemes for first order hyperbolic equations on a domain between two spheres will be presented. The approach exploits cartesian data structure of a cubed sphere mesh and operator splitting. Construction of numerical schemes is performed in three steps. First, a semidiscrete scheme is constructed by means of a finite volume method. Then operator splitting is used in a such way that each split equation accounts for one predefined direction only. Finally, an implicit time discretization is done. The resulting fractional step scheme is conservative and stable for large CFL numbers. Numerical results will be presented. Feasibility of the developed approach for some parabolic equations, for a generic PDE solver on a cubed sphere, and for mesh refinement procedures will be briefly discussed.

14: Computational Sciences, Posters

IC/PP4289/015: ***Ab initio* and modeling study of some amino acid-tRNA: NMR shielding and thermodynamic of solvent effect.**

Presenter: Hadieh Monajemi (University of Malaya, Malaysia)
Co-author: W.A.T. Wan Abdullah (University of Malaya, Malaysia)
Co-author: Sharifuddin Zain (University of Malaya, Malaysia)

tRNA takes suitable amino acid to the ribosome for the formation of peptide bonds. In starting a peptide chain, the first amino acid which is taken to the ribosome is methionine. We simulated methionine-amino acid bondings and amino acid-tRNA bondings using mixed study of quantum mechanics ab initio calculation and molecular mechanics. NMR shielding tensors, thermodynamic parameters and total energies have been calculated. It is important to try to answer the question what kind of physical properties and environmental conditions regarding the dipeptides cause tRNA to attach to a wrong amino acid. In fact one of these properties is dielectric, which we calculate its effect.

IC/PP4783/142: The ill-posed retrieval of aerosol extinction coefficient profiles.

Presenter: Pornsarp Pornsawad (Universität Potsdam, Germany)
Co-author: Christine Böckmann (Universität Potsdam, Germany)
Co-author: Christoph Ritter (Alfred Wegener Institute, Germany)
Co-author: Mathias Rafler (Universität Potsdam, Germany)

We regard an ill-posed problem which is ill-posed in the sense that one has to calculate the derivative from noisy data. We prefer to use Tikhonov regularization [1] and a variational method [2] to stabilize the problem. The particular application concerns the retrieval of optical backscatter and extinction coefficient profiles from lidar (*l*ight *d*etection *a*nd *r*anging) signals of aerosol layers in our atmosphere. Since the traditionally used methods show often an unstable behavior we developed and compared three new possibilities. Aerosol extinction and backscatter coefficient profiles were statistically and numerically retrieved from the EARLINET lidar database [3] simulated at the wavelengths 355, 387, 532 and 607 nm with realistic experimental and atmospheric conditions taken into account. Firstly, in using a statistical technique adapted from [4] the density and range corrected signal (RCS) were separately fitted by linear, quadratic and cubic model to avoid an *a priori* assumption on the behaviour of function to be regress. A chi-squared test was used to be the criteria to choose a good fit model for RCS. Secondly, Tikhonov regularization was performed on the calculation of the derivative together with the implementation based on the natural cubic spline. To avoid the task concerning the selection of a suitable regularization parameter and to overcome the instability of traditional methods such as difference methods and interpolation methods, thirdly, a variational method for differentiation was applied. The results were compared with two traditionally used methods. It turns out that all the three developed methods are more accurate than the traditional ones. In spite of the big numerical effort of the variational method it is the most stable one. [1] Wang et al(02) Inverse Problem 18. [2] Knowles et al(95) Numer Math 70. [3] Pappalardo et al(04) Appl Opt 43. [4] Russo et al (06) Appl Opt 45.

IC/PP1052/015: Double-diffusive mixed-convection in a lid-driven cavity under the counter-acting buoyancy forces.

Presenter: Dilip Maiti (Birla Institute of Technology & Science, India)

Present study deals with steady two-dimensional flow accompanied by heat and mass transport in a lid-driven square cavity filled with a mixture of a solvent vapor and non-condensable gas subjected to the vertically parallel thermal and solutal gradients. The top lid is maintained at constant speed while other three walls are kept fixed. Zero heat and mass fluxes are imposed on the vertical side walls. The governing unsteady Navier-Stokes equations combined with the heat and mass transport equations are solved numerically through a finite volume method on a staggered grid system using QUICK scheme for convective terms. The resulting equations are then solved by an implicit, time marching, pressure correction based SIMPLE algorithm. The essential details of flow, temperature and concentration fields are presented for the opposing buoyancy forces ratio $B < 0$ with special attention being given to find the values of parameters- such as Reynolds number, thermal and solutal Richardson number and the buoyancy forces ratio- for which the flow in the cavity is fully dominated by either lid-driven convection or thermal- or solutally-induced convection/conduction.

15: Modelling and Simulation, Minisymposia

IC/MP338/010: **Study groups with industry.**

Organiser: Hilary Ockendon (University of Oxford, UK)

This minisymposium will showcase the Study Groups with Industry which have been used world-wide to provide an effective mechanism to make contacts between academic mathematicians and industrial scientists. The four presentations will show how these meetings have evolved in different countries and will describe some case studies.

Industrial mathematics initiatives in the Western Pacific region. **Graeme Wake** (Massey University, New Zealand) IC/MT382/010

Since the 1980s the Australian and New Zealand Applied Mathematics fraternities have operated a Mathematics-in-Industry Study Group. After a consolidating period this annual event became a key activity of a special interest group of the Australian and New Zealand Industrial and Applied Mathematics (ANZIAM) organisation. This activity has been held in different centres in Australia and New Zealand with a view to seeding ongoing activity in each area. In 2007 it moved to the University of Wollongong in Australia and includes interactive web-based activity. This talk will review the recent activities of the ANZIAM MISGs, giving special attention to the evolving differences we have effected such as: student moderators, contract negotiations, publications, international outreach, etc. Within New Zealand efforts are being made to develop an activity modelled on the successful Smiths Institute at Oxford.

Graph colouring for office blocks. **David Allwright** (University of Oxford, UK) IC/MT384/010

Most modern office blocks have different companies working in the same building, so the use of wireless computer networks (WLAN) introduces a security problem. It is impracticable to have complete electromagnetic screening around each company's *territory*. However, BAE SYSTEMS have developed a frequency selective surface that could be used on walls and ceilings, such that transmission across *two* such interfaces would be undetectable. But companies either side of *one* wall or floor/ceiling would still need to be on *different* WLAN channels. How many channels are needed for a typical building, and how can a good assignment be found? The talk will describe how the UK Study Group addressed these questions, which are graph colouring for the adjacency graph of the 3-dimensional territories.

An interesting specific case is how many channels are needed if each territory is a cuboid (aligned with a fixed set of Cartesian axes). The talk will include Bruce Reed and Adrian Vetta's ingenious construction to answer this question, showing that for n cuboids the number of channels may need to be of order $\log\log n / \log\log\log n$, and can therefore be arbitrarily large.

Study groups in Denmark: a tale of two cities. **Poul Hjorth** (Danmarks Tekniske Universitet, Denmark) IC/MT1413/010

Since 1998 European Study Groups with Industry have been held in Denmark, and Danish companies varying from LEGO and NOVO to very small high-tech firms continue to participate. In this talk I will briefly describe the history, the organisation and the format of the Danish Study Groups, and highlight a few particularly interesting problem solutions.

Case studies from the Canadian and Chinese SGs. **Huaxiong Huang** (York University, Canada) IC/MT2251/010

In this talk we will present a few case studies on problems submitted to the Canadian and Chinese Study Groups (SGs). The Canadian SG started in 1998 (with help from OCIAM) and have been held annually in Western Canada by the Pacific Institute for the Mathematical Sciences. SG in other parts of the Canada were also held, most recently in Toronto by the Fields Institute. The Chinese SG, including the ones in Hong Kong, started in Fudan University with supports from the Chinese NSF, the Royal Society of London and OCIAM. Over the years, we have worked on problems from industry as well as from government research labs, health and medical centers and financial institutions. If time permits, some details will be given on modeling InSb crystal growth, one of the SG problems which evolved into a collaborative project and produced two PhD and one Master's dissertations.

IC/MP228/010: **On morphology of growing surface of crystals.**

Organiser: Etsuro Yokoyama (Gakushuin University, Japan)
Co-organiser: Yoshikazu Giga (University of Tokyo, Japan)

The morphological prediction of a crystal is interdisciplinary and is related to various subjects, transport and diffusion phenomena, physical chemistry of surface and interface, nucleation, chemical reactions, convection surrounding a crystal, and phase transformation, which involves a lot of mathematical problems, such as morphological instabilities. The pattern of a growing crystal depends not only on crystal structure but on conditions in the nutrient phase, e.g. temperature and concentration, which influence the growth speed of each element of the interface. In addition, the growth speed of each element depends on the local geometry of the interface, specifically on the interface curvature and the orientation of the interface relative to the crystal axes. Furthermore, the growth speed of interface is affected by impurities over the interface, and by the presence of defects of the interface. In the physics and chemistry of surface, recently, the development of numerous techniques of in situ observation is able to reveal not only step motion along the interface but diffusion of admolecules and/or impurities over the interface. The structure of growing interface has been studied using various Monte Carlo simulations and recently the model of spiral motion to occur with aid of screw dislocations is proposed using by a level set method. The formation of patterns during growth of a crystal is a difficult free boundary problem and can be solved using by numerical techniques, such as a boundary integral method, recently a phase field model and more recently a level set method. The speakers present an overview of research on morphology of growing surface of crystals both in experimental and theoretical aspects.

Evolution of polyhedral crystals. **Przemyslaw Gorka** (Politechnika Warszawska, Poland) IC/MT2714/010

We consider a system modelling evolution of a single crystal grown from vapor. We account for vapor diffusion and Gibbs-Thomson relation on the crystal surface. We also assume that the velocity of the growing crystal is determined by the normal derivatives of concentration of vapor at the surface. Mathematically speaking, this is a one-phase Stefan-type problem with the curvature and kinetic term. We show local in time existence of solutions assuming that the initial crystal is an arbitrary admissible polyhedral shape.

Crystal growth in deposited snow: experiment, physical modeling and simulation. **Frédéric Flin** (Mateo, France), Jean-Bruno Brzoska (Centre d'Etudes de la Neige, France), Yoshinori Furukawa (Hokkaido University, Japan) IC/MT2834/010

Snow, from its fall until its full melting, undergoes transformations of its microstructure with time. This process, named *metamorphism*, drastically influences its physical, thermal and mechanical properties and is of great interest in snow and ice sciences. The recent possibility of acquiring 3D images of small snow samples opens new opportunities for investigating snow in details. For this purpose, we developed specific algorithms in order to extract the relevant geometrical and physical parameters from the imaged samples (e.g. normal and curvature fields, surface area). We then used these estimators to develop 3D models that simulate the time-lapse transformations of snow directly from an experimentally observed microstructure. These models, which can be checked with experiments in cold room, offer new outlooks for the study of snow metamorphism.

Morphological stability of a growing faceted crystal. **Etsuro Yokoyama** (Gakushuin University, Japan), Yoshikazu Giga (University of Tokyo, Japan) IC/MT4183/010

We review briefly studies of morphological instability of a growing faceted crystal, in which the interplay between nonuniformity in supersaturation on a growing facet and anisotropy of surface kinetics derived from the lateral motion of steps, leads to a faceted instability, i.e., preferred growth of corners and edges of the faceted crystal. As long as the nonuniformity in supersaturation on the facet is not too large, it can be compensated for by a variation of the density of microscopic growth step along the facet. We discuss the time dependent behavior of local step density on the growing macroscopically flat facet under a given nonuniformity in supersaturation along the surface by means of the characteristics for a first order partial differential equation of growing surface and show that the asymptotic behavior of local step density can be determined by the variation of reciprocal of supersaturation under the conditions of stability.

Multi-phase systems with anisotropic surface energies and volume constraints. **Björn Stinner** (University of Sussex, UK) IC/MT4321/010

The dynamics of phase boundaries in multi-phase systems has been studied with a focus on interfacial energy contributions. The aim has been a diffuse interface description based on the phase field methodology which, in the sharp interface limit, is related to a classical description with moving hypersurfaces modelling the phase boundaries. A nontrivial task in the case of multiple phases is to let surface quantities as (possibly anisotropic) surface energies and mobility coefficients enter the equations of the diffuse interface model in the right way. Volume constraints for (some of) the phases lead to nonlocal partial differential equations. Depending on the multi-well potential used for the phase field equations several numerical methods will be presented taking that constraints into account.

IC/MP257/015: Modeling and simulation for nano-scale materials.

Organiser: Luis Bonilla (Universidad Carlos III de Madrid, Spain)
Co-organiser: Russel Caflisch (University of California, Los Angeles, USA)

The nanoscale physics and structure of materials are of vital importance for modern science and technology. Examples include microelectronic devices and possible successors to CMOS technology, strength and plasticity of materials, and high-speed sensors. Modeling and simulation for nanoscale materials faces considerable challenges because of their complexity, as well as their dependence on multiple length and time scales (ranging from Angstroms and femtoseconds to centimeters and seconds) and multiple physics descriptions. This minisymposium will focus on new analytic, modeling and simulation methods for nanoscale materials, in particular for defects in these materials. Defects (for example cracks, dislocations, stacking faults and substitutional defects) can have significant, even determining, effects on material strength, reliability of device properties and self-assembly of structures. The presentations in the minisymposium are as follows.

The first talk describes a novel algorithm for kinetic Monte Carlo simulations which is based on exact Green's functions of the theory of first-passage processes and is applicable to a wide range of physical situations where multiple Brownian particles of finite dimensions diffuse, collide and react with each other. Applications include Oswald ripening, semiconductor processing, defect microstructure evolution in fusion and fission reactor materials, and diffusion-controlled reactions in confined geometries.

The second talk deals with discrete models of defects in crystal lattices, which are the basis of macroscopic properties such as the strength of materials and control their mechanical, optical and electronic properties. Discrete models will be used to study the interaction and motion of dislocations, and to define and analyze dislocation densities.

The third presentation will discuss the role of dislocations and alloying in self-assembly and directed self-assembly for quantum dots, using a level-set method to simulate epitaxial growth and an algebraic multigrid method for the simulation of atomistic strain. These methods are designed to include both continuum and atomistic length scales.

The fourth talk will concern non-separability of length scales in solid mechanics, due to severe nonlinearity, and its role on multi-stability of a mechanical system at a micro-level.

First passage Monte-Carlo: diffusion without all the hops. **Vasily Bulatov** (Lawrence Livermore National Laboratory, USA), Tomas Oppelstrup (NADA, KTH-Royal Institute of Technology, Sweden), Aleksandar Donev (Lawrence Livermore National Laboratory, USA), Babak Sadigh (Lawrence Livermore National Laboratory, USA), Malvin Kalos (Lawrence Livermore National Laboratory, USA), George Gilmer (Lawrence Livermore National Laboratory, USA) IC/MT1477/015

We present a novel Monte Carlo algorithm for N diffusing particles of finite sizes that react on collisions. Using the solutions of the theory of first passage processes and time dependent Green's functions, we break the difficult N-body problem into independent single- and two-body propagations circumventing numerous diffusion hops used in standard Monte Carlo. The new algorithm is exact, extremely efficient and applicable to many important physical situations in arbitrary integer dimensions.

Rate-independent plasticity and criticality. **Lev Truskinovsky** (École Polytechnique, France) IC/MT1733/015

We show that the classical singular dissipative potential of the phenomenological rate independent plasticity can be obtained by homogenization of a micro-model with quadratic dissipation. The essential ingredient making this reduction possible is a rugged energy landscape at the micro-scale, generating under external loading a cascade of subcritical bifurcations. Such landscape may appear as a result of a sufficiently strong pinning or jamming of defects, leading to elastic micro-metastability. The homogenized system behaves as marginally stable or critical. Already in two dimensions the criticality manifests itself through power law acoustic emission.

Growth and pattern formation for thin films. **Russel Caflisch** (University of California, Los Angeles, USA) IC/MT2075/015

Growth of an epitaxial thin film involves physics on both atomistic and continuum length scales. For example, diffusion of adatoms can be coarse-grained, but nucleation of new islands and breakup for existing islands are best described atomistically. The lattice properties of the film are determined by those of the underlying substrate. In heteroepitaxial growth, e.g., Germanium on Silicon, mismatch between the lattice spacing of the Silicon substrate and the Germanium film will introduce a strain into the film, which can significantly influence the material structure, leading for example to the formation of quantum dots. Technological applications of quantum dot arrays require a degree of geometric uniformity that has been difficult to achieve. One approach to overcoming this difficulty is to prepattern the system, for example with buried dislocation lines. This talk will describe mathematical modelling, simulation methods and computational results for epitaxial growth, strain in thin films and pattern formation. The growth simulations use an island dynamics model with a level set simulation method. Strain computations can be computationally intensive, so that effective simulation of atomistic strain effects relies on an accelerated method that incorporates algebraic multigrid and an artificial boundary condition. Simulations that combine growth and strain will be presented showing spontaneous and directed self-assembly of patterns (quantum dots and wires) on thin films.

Dynamics of defects in crystal lattices and bifurcation theory. **Luis Bonilla** (Universidad Carlos III de Madrid, Spain), Ana Carpio (Universidad Complutense de Madrid, Spain) IC/MT2363/015

Crystal defects such as dislocations are the basis of macroscopic properties such as the strength of materials and control their mechanical, optical and electronic properties. Advances in electronic microscopy have allowed imaging of atoms and therefore to visualize the core of dislocations, cracks, and so on. In continuum mechanics, dislocations are treated as source terms proportional to delta functions supported on the dislocation line. Cores and crystal structure are not properly considered and it is hard to describe the motion of crystal defects. Unlike defects in fluids (such as vortices), dislocations move only within glide planes, not in arbitrary directions, and they move only when the applied stress surpasses the Peierls stress, which is not infinitesimal.

We have proposed a discrete model describing defects in crystal lattices with cubic symmetry and having the standard linear anisotropic elasticity (Navier equations) as its continuum limit. Moving dislocations are traveling waves which become stationary solutions if the applied stress falls below the Peierls value. The corresponding transition is a global bifurcation of the model equations whose type depends on whether the chosen dynamics includes dissipation. In addition, homogeneous nucleation of dislocations occurs when a sufficient shear stress $F > F_c$ is applied to a dislocation-free crystal. Then the strained dislocation-free state becomes unstable via a subcritical pitchfork bifurcation at $F = F_c$. The bifurcation diagram is studied by numerical continuation and a mechanism to select simultaneously stable configurations containing different number of edge dislocations is analyzed.

IC/MP641/015: Mathematical, computational and statistical modelling in metrology.

Organiser: Maurice Cox (National Physical Laboratory, UK)
Co-organiser: Alistair Forbes (National Physical Laboratory, UK)
Co-organiser: Markus Bär (PTB-Berlin, Germany)

Metrology, the science of measurement, is fundamental to a vast range of activity worldwide, providing critical support for manufacturing, quality of life, health, environment and climate change as well as all major scientific disciplines. The annual expenditure on measurement within the European Union alone is estimated to be over 80 billion euros (100 billion USD). Metrology has drawn heavily from many mathematical disciplines, including applied mathematics, numerical analysis, optimisation and data approximation. In recent years, the importance of developing valid statistical models associated with measurement systems has been recognised in order that scientific inferences (e.g., uncertainty statements, go/no-go decisions) made on the basis of measurement data are reliable. Much of quantitative analysis in metrology now occupies an interesting and challenging intersection of mathematics and probability theory. In parallel, advances in algorithms and computational methods open up the possibility that the outcome of measurements can be obtained from simulation of suitable mathematical models (*virtual experiments*). If metrology is currently seen as mainly an experimental science, the role of computation is increasing. This mini-symposium will report on recent advances in the application of mathematical, computational and statistical modelling to metrology, especially in the areas of modelling measurement systems, parameter estimation, the propagation of distributions and uncertainty evaluation, and the design and analysis of interlaboratory comparisons.

Mathematical modelling and measurand identification required for defining mises en pratique *of the Kelvin.* **Franco Pavese** (Consiglio Nazionale delle Ricerche, Italy), Daniela Ichim (Istituto Nazionale di Statistica, Italy) IC/MT4091/015

For some physical quantities, the method of defining mises en pratique of the unit for practical standards is used, allowing one or more defined implementations. This was in 2005 the case of temperature by transforming ITS90 and PLTS2000 into two mises en pratique, with possible further mises en pratique in future. Temperature, as an intensive quantity, requires the definition of a scale as the actual measurement standard. One possible future direction for mises en pratique is to furtherance the realisations of the thermodynamic scale that so far only represented the physical bases of the definition of the empirical scales. A second one is arising from the fact that the addition of further mises en pratique only requires all being compatible with each other, to avoid ambiguities in the definition of the temperature values. Other scales that presently are approximations for the ITS90 could become mises en pratique, also for lower accuracy levels. In addition, the use of mises en pratique can alleviate presently conflicting issues about measurand definition in comparisons. A big variety of modelling requirements corresponds to the variety of definitions: in fact they range from thermodynamic ones, requiring a correct physical modelling, to semiempirical, to empirical ones. Since temperature can be measured only by measuring another physical quantity, e.g., electrical resistance, pressure, a change in length, etc., the measurand related to each of the above definition must be correctly and clearly identified, which can be less obvious than it might look. The presentation will first introduce the general thermometric problem, limited to making the subsequent illustration of the problems concerning measurand identification and modelling issues understandable. Then it will summarise the correct procedures to correctly and clearly identify the measurand of each given definition, whith examples of possible ambiguities. Finally it will illustrate the characteristics of the main families of models suitable for use in temperature scales, used or candidates for use as mises en pratique of the kelvin, from the viewpoint of the metrologist, concerning either the mathematical requirements and the requirements of the statistical treatment of the experimental temperature data.

Challenges for mathematical and statistical modelling for metrology. **Maurice Cox** (National Physical Laboratory, UK), Alistair Forbes (National Physical Laboratory, UK), Peter Harris (National Physical Laboratory, UK) IC/MT4149/015

A glance through recent volumes of journals such as *Metrologia*, *Measurement*, and *Measurement Science and Technology* indicates the considerable extent to which mathematical and statistical modelling are used in metrology. Seven volumes of *Advanced Mathematical and Computational Tools for Metrology*, resulting from conferences in the area, reinforces this view. Publication of a special issue of *Metrologia*, with a number of downloads in the month following publication double that for a typical issue, provides further evidence of the relevance of statistical methods for metrology.

This paper looks at three aspects of the mathematical and statistical treatment of measurement problems and associated journal articles.

One, who writes these articles? Who uses them and to what extent? How large is the take-up gap between the relatively academic presentation of the writer and the sometimes limited mathematical and statistical knowledge of the practising metrologist as reader? Are there better ways of conveying information?

Two, do the published articles address actual problems of metrological concern? The answer is “yes” in some but not all respects. Do the solutions proposed account for the measurement information available, or turn a blind eye to part of it in order to derive a simpler solution?

Three, to what extent do paper writers and practising metrologists form distinct camps? Co-working is improving, but not at a rapid rate. Development of a mathematical or statistical model requires the involvement of both parties to maximize its value. A key area is uncertainty evaluation in the context of a model of measurement, where quantifying and coping with uncertainty structures benefits from joint consideration by all concerned.

This paper discusses the challenges implied by these questions.

Atomistic modelling in metrology: algorithms and current challenges. **Vlad Sokhan** (National Physical Laboratory, UK) IC/MT4175/015

Mathematical modelling plays an increasingly important role in measurement science where many problems of fundamental and practical importance require solutions at meso and nano scales. In quantum and materials metrology atomistic simulation has developed to a level where it is competing in accuracy with laboratory measurements.

In this talk an overview of recent algorithmic development and applications of atomistic simulation to problems of metrology will be given.

Uncertainty evaluation for parametric and semi-parametric modelling. **Clemens Elster** (PTB-Berlin, Germany) IC/MT4277/015

Uncertainty evaluation for parametric modelling is considered in the context of regression analysis. Application of maximum likelihood as well as Bayesian statistics are discussed for parameter estimation in the context of particular metrology-relevant aspects such as the presence of non-random (systematic) measurement errors.

The extension of parametric to semi-parametric modelling is considered for the task of spectral analysis. The particular semi-parametric model to be treated requires the estimation of a smooth baseline signal in addition to the adjustment of a parametric model for the spectrum. A regularization approach is proposed leading to a spline solution for the baseline. The regularization approach is regarded from a Bayesian point of view which is then used for uncertainty evaluation. The particular semi-parametric modelling approach is finally illustrated by means of an example from NMR spectroscopy.

IC/MP641/015: Mathematical, computational and statistical modelling in metrology. #2

Organiser: Maurice Cox (National Physical Laboratory, UK)
Co-organiser: Alistair Forbes (National Physical Laboratory, UK)
Co-organiser: Markus Bär (PTB-Berlin, Germany)

(For abstract, see session #1 above.)

Partial differential equations and inverse problems in metrology (overview talk). **Markus Bär** (PTB-Berlin, Germany) IC/MT4278/015

Many measurement systems are adequately modelled by partial differential equations (PDEs). This talk describes various applications of PDEs models in metrology. In the first part, general aspects of PDEs in metrology and the use of well-established models like the heat equation or Maxwell’s equation for current metrological applications is reviewed. The emphasis is on the realization of "virtual experiments" and, in particular, on the demand of solving inverse problems. This

is needed in many modern metrological applications in order to determine material or geometry parameters of a given unknown probe. In more detail we will report on recent progress in solving the inverse problem for scatterometry of visible light and extreme UV radiation at masks employed in chip production. Finally, we will address the problem of a proper metrological treatment of a much more complex system of partial differential equations, namely the quantitative modelling of electric and magnetic phenomena in human and animal hearts. First steps towards a quantitative heart modelling based on measurements of physiological and anatomical parameters are presented for the examples of a rabbit heart and a human heart. The simulation results are compared to measurements of electric potentials on the surface of isolated hearts as well as to electro- and magnetocardiographic recordings.

Joint work with: S. Bauer, H. Gross, R. Model (PTB Berlin, Germany) and A. Rathsfeld (Weierstrass-Institute of Applied Analysis and Stochastics, Berlin, Germany)

Propagation of uncertainties in measurements using fiducial inference. **Chih-Ming Wang** (National Institute of Standards & Technology, USA), Hari Iyer (National Institute of Standards & Technology, USA) IC/MT4315/015

We present an alternative approach to the ISO *Guide* for evaluating uncertainty in measurements. The approach, based on FisherŠs fiducial arguments, can easily and naturally incorporate both type-A and type-B information into the model assumptions, and calculate the uncertainty for a measurand of interest. The approach can be applied to measurement models having vector-valued input quantities and measurand, and generally makes use of Monte Carlo simulation to evaluate measurement uncertainty. Examples are used to illustrate the procedure.

A novel approach using parallel Kalman filters in time and frequency estimation. **Ragne Emardson** (SP Technical Research Institute of Sweden) IC/MT4564/015

Accurate knowledge of time and frequency plays a fundamental role in many applications in our information based knowledge society. UTC, which is the basis of world time distribution, is a combination of the atomic time scale TAI and earth rotation information. TAI is calculated by the International Bureau of Weights and Measures (BIPM) in Paris as a weighted average of more than 200 atomic clocks. As the definition of swedish national time is based on UTC, good estimates of a clock's deviation from UTC is crucial for high-performance time keeping. For many applications, real time estimates of the clock's time and frequency error are required. We have developed a novel approach for estimating time and frequency errors based on a assembly of clocks of varying quality. This approach is based on using parallel Kalman filters in order to utilize all available measurements in the estimation. As these measurements are available with different delays, the Kalman filter produce estimates of different quality. One filter may produce real-time estimates while another filter waits for more measurements. When new information becomes available, the parallel Kalman filters exchange information in order to keep the state matrices updated with the most recent information. In Kalman filtering accurate modelling of the measurement system is fundamental. All the contributing clocks, as well as the time transfer methods, are modelled as stochastic processes. By using this methology, we can at every epoch obtain "optimal" estimates of time and frequency errors of a specific clock. By correctly modelling the contributing clocks and time transfer links, we may also estimate the uncertainty of each time and frequency estimate.

IC/MP706/015: Wave structures and complex dynamics in models of highway traffic.

Organiser: Richard Wilson (University of Bristol, UK)

The modelling of highway traffic is an area of huge economic importance: in the UK alone, it is estimated that traffic jams cost the economy more than 20bn GBP annually. Furthermore, there is a general trend in using information and communication technology to try to influence driver behaviour and control congestion. However, despite over 50 years of research, there is still a need to improve the basic understanding of the dynamics of highway traffic. A lot of interesting questions remain both in terms of modelling and in terms of mathematical analysis.

In the literature there are very many models of highway traffic, and these may be classed as either macroscopic (averaged and fluid-like, usually PDEs) or microscopic (modelling vehicles at the individual level). Moreoever, there are subdivisions of these classes and overlaps between them. For example, the microscopic class breaks down into car-following models (which consider vehicles to be discrete entities moving in continuous time and space) and cellular automata models (where vehicles, time and space are discrete and where dynamics are driven by stochasticity). There are however connections across the scales between the different model types; for example, the emergent macroscopic dynamics of car-following models may be described by PDEs.

This minisymposium will provide a melting pot where practitioners of the different modelling approaches are brought together. We will explore the underlying mathematical mechanisms for the complex dynamics that models exhibit, and we will seek connections across the scales between different model types. Comparisons with empirical traffic data will also be sought. Hence we anticipate that this minisymposium will help lay the foundation stone of a new multiscale framework for understanding traffic flow.

Spatio-temporal pattern in highway traffic: empirical data and modelling approaches. **Richard Wilson** (University of Bristol, UK) IC/MT3955/015

In this talk I will describe the key spatio-temporal features of empirical highway-traffic data and I will summarise their 50 year old modelling history. I will then focus on the nonlinear behaviour of microscopic car-following models in particular, and I will show how dynamical systems techniques may be used to understand the fundamental mechanisms behind traffic jam generation. Finally, I will illustrate connections to macroscopic PDE theory and outline possible future directions.

Rigorous techniques for analyzing CA traffic models. **Lawrence Gray** (University of Minnesota, USA) IC/MT3357/015

Cellular automata (CA) were first used to model traffic by Nagel and Schreckenberg. These models are discrete, both in space and in time, and yet they exhibit many of the interesting complex phenomena that are characteristic of actual traffic. Their discrete nature makes them easy to describe and easy to simulate.

During the past few years, techniques have been developed for rigorous mathematical analysis of CA traffic models, primarily for a variation on the Nagel-Schreckenberg model introduced by Gray and Griffeath. This analysis brings a number of other particle models into play, including the "branching annihilating random walk" and the "chipping model". Comparisons between models are facilitated by a mathematical technique known as "coupling". Standard coupling methods have not been applica-

ble to most CA traffic models, but recent ideas have changed this.
These new ideas will be described, and it will be seen that the resulting mathematics provides some insights into the phenomena that make traffic so interesting.

Some microscopic–macroscopic problems arising in the mathematical study of second order models of traffic flow. **Michel Rascle** (Université de Nice, France), Salissou Moutari (Université de Nice Sophia Antipolis, France) IC/MT3895/015

I will first describe various aspects of mathematical and modeling problems arising (in particular) in the description of traffic flow by the class of fluid "second order" models, introduced several years ago in Aw-Rascle, SIAP, 2000 ("Resurrection"), in connection with the celebrated ("Requiem ...") paper of Daganzo in 1995.
This class of models is the natural extension of "first order models", i.e. of scalar conservation laws. Moreover, they are also the (rigorous) limit of discrete Follow-the-Leader Models in a hyperbolic scaling : $(x,t) \to (\varepsilon x, \varepsilon t)$, as shown with Aw, Klar and Materne, SIAP 2002.
In recent years, there has been a large amount of work devoted to apply these various types of models to realistic situations, such as junctions, networks, complex flows etc., and/or to combine them via hybrid schemes. Depending on the time, I will describe some of these aspects.

Travelling waves on lattices defined by car-following models. **Antony Humphries** (McGill University, Canada) IC/MT4999/015

We consider the dynamics of microscopic car-following models on an infinite highway. Such models take the form of a lattice differential equation system, whose travelling wave solutions are defined by a delay differential equation boundary value problem. When reaction times are included, advanced-retarded FDE problems arise. We will use manifold dimension counting arguments to analyse the genericity of such solutions, and numerical continuation techniques determine domains of existence and solution forms, and identify connections with macroscopic PDE traffic theory.

IC/MP706/015: Wave structures and complex dynamics in models of highway traffic. #2

Organiser: Richard Wilson (University of Bristol, UK)

(For abstract, see session #1 above.)

Three characteristic times: how the reaction time, the update time, and the adaptation time influence stability of traffic flow. **Martin Treiber** (TU Dresden, Germany) IC/MT3897/015

In the context of microscopic traffic models, there are three characteristic time constants that influence the dynamics and stability of traffic flow: The reaction time of the drivers, the velocity adaptation time needed to accelerate to a new desired velocity, and the numerical update time. In spite of their conceptual differences, these times are often confused. Particularly, the update time of iterated maps (such as the Newell model) or the adaptation time of time-continuous models (such as the optimal velocity model) are often treated as a 'reaction time'. In this contribution, we numerically investigate how these times influence the local and string stability of a platoon of vehicles. In particular, we found that the numerical update time is dynamically equivalent to half the reaction time. Furthermore, with respect to stability, there is an 'optimal' adaptation time as a function of the reaction time.

Multi-lane models of traffic flow across the scales. **Jon Ward** (University of Bristol, UK) IC/MT3609/015

Motorway traffic is a discrete dynamical system of interacting particles. However, many mathematical approaches model it as a continuum with fluid-like properties. In this talk we will investigate how multi-lane microscopic models of traffic flow can be used to infer desirable properties for equivalent macroscopic models. We will also analyse how spatio-temporal phenomena express themselves in models of different scales.

A hybrid Lagrangian scheme for vehicular traffic flow. **Salissou Moutari** (Université de Nice Sophia Antipolis, France) IC/MT5057/015

In this talk, we will present a simple fully discrete hybrid model for vehicular traffic flow, based on a Lagrangian discretization of the Aw–Rascle model[1]. The main idea is to combine the microscopic description of the traffic (around an obstacle such as traffic light, toll station, intersections, etc.) with a macroscopic description (away from the obstacles). Due to the Lagrangian modelling, we have no lost or gain of mass at the interfaces. We will briefly describe how to establish the BV estimates for the whole hybrid model. Finally we will present some few numerical simulations of this hybrid scheme in the case of traffic light, especially with different CFL conditions in the microscopic and macroscopic regimes.

[1] Aw, A. and Rascle, M.; SIAM J. Appl. Math., 60 (2000).

Calibration of microscopic traffic-flow models: what can be learned for the wave-structure formation on highways?. **Peter Wagner** (German Aerospace Center, Germany) IC/MT3400/015

By using the trajectory data provided by the NGSIM project, the parameters of microscopic models could be calibrated to the data at hand. Several possibilities to do this are discussed and tested, which leads to a whole distribution of the parameters of the model in use. After doing so, it could be discussed which kind of traffic pattern could be reproduced with which kind of microscopic traffic flow model, and, more interestingly, what can not be reproduced. This should shed light on the ongoing discussion about the traffic flow patterns called synchronized traffic flow, to help understanding its nature.

IC/MP711/010: The mathematics of food: modelling and computation.

Organiser: Arthur Parrott (University of Greenwich, UK)
Co-organiser: Andrew Lacey (Heriot-Watt University, UK)

There is a growing interest in applying mathematics to the solution of problems arising out of food engineering, an area traditionally dominated by experimental approaches. This minisymposium focuses on problems where the complexity either of the food material or of the process or both leads to interesting and challenging problems either in mathematical or computational modelling. In many cases there are specific food-related features that dictate a novel approach to the solution and the use of conventional Heat Transfer and CFD packages is not possible. Examples of this type of problem include texture development governed by internal moving boundaries in foam-like dough during baking, domestic microwave thawing requiring a coupled computational approach with both computation of heat transfer and the numerical solution of MaxwellŠs equations in moving domains, scraped surface heat exchangers where heat transfer and flow occur on a very wide range of length scales and the frying of porous materials where detailed modelling results in non-standard moving boundary problems.

Crust formation in bread baking. **Andrew Lacey** (Heriot-Watt University, UK) IC/MT3466/0

A model for the formation of a crust during bread baking is presented. The crust is the outermost part of the loaf where the final bread density is significantly higher than in the interior of the loaf, called the crumb. Our model is based on a collapse mechanism, whereby raised pressures in the interior part of the loaf, due to thermal expansion and water evaporation, squash bubbles in the outer part of a bread loaf at the same time as the bread sets and fractures. The latter process allows vapour to escape from bubbles which can then shrink.

Mathematical models for frying processes. **Mario Primicerio** (Università degli Studi di Firenze, Italy) IC/MT3568/0

We present mathematical models for the process of frying a rather thick sample of an non-deformable porous material saturated with water (e.g. a potato slice). The models are based on thermodynamical arguments and result in a class of initial-boundary value problems for a system of equations satisfied by the temperature, pressure and vapour content; in the case of one-dimensional geometry, the domain in the x-t plane is decomposed in subregions where the porous medium may be totally saturated, partially saturated, or completely dry. Correspondingly, the free boundary conditions are discussed. We provide a preliminary analysis and present some results of numerical simulations

Microwave modelling and validation in food-thawing applications. **Arthur Parrott** (University of Greenwich, UK), Tim Tilford (University of Greenwich, UK) IC/MT4229/0

Thawing of a frozen food product in a domestic microwave oven is simulated numerically using a coupled solver approach. The approach utilises a dedicated electromagnetic FDTD solver which is closely coupled to an unstructured FVM multi-physics package. Two overlapping numerical domains are defined; the food material and container were meshed for heat transfer and phase change solution, whilst the microwave oven cavity and waveguide are meshed for the microwave irradiation. The two solution domains are linked using a cross-mapping routine. This approach allows the rotation of the food load to be captured. Power densities obtained on the structured FDTD mesh are interpolated onto the unstructured FVM mesh for each time-step/turntable position. The FVM solver utilises the power density data to advance the temperature and phase distribution solution. The temperature-dependant dielectric and thermo-physical properties of the food load are updated prior to revising the electromagnetic solution. Changes in thermal/electric properties associated with the phase transition were fully accounted for as well as heat losses from product to cavity. Two scenarios were investigated: a centric and eccentric placement on the turntable. Developing temperature fields predicted by the numerical solution are compared against experimentally obtained data. Presented results indicate the feasibility of fully coupled simulations of the microwave heating of a frozen product. The agreement between numerical and experimental solutions is good whilst the food is frozen, but deteriorates after thawing. The variation in heating pattern due to eccentric placement is shown.

IC/MP669/151: Dynamics of cutting processes.

Organiser: David Barton (University of Bristol, UK)

Machining operations, such as high-speed milling or drilling, are among the most widely used of all manufacturing processes. Cost efficiency and accuracy are important, however high-performance machining is prone to self-excited chattering behaviour which leads to increased tool wear, inferior surface quality and poor dimensional accuracy. Furthermore, at the most efficient parameter settings, chattering motions can occur spontaneously, hence automated processes are often planned conservatively.

This mini-symposium is focused on understanding the dynamics (both linear and nonlinear) of different cutting operations and using this knowledge to improve the efficiency while maintaining accuracy and surface quality. It will start with an overview of the subject area, which will then be followed by a series of talks focusing on modelling, analysis, and experimental investigation of different cutting operations. Particular emphasis is placed on the study of the fly-over effect during chatter and associated non-smooth behaviour including the bifurcations that cause its onset.

The nonlinear dynamics of cutting processes. **Gabor Stepan** (Budapest University of Technology and Economics, Hungary) IC/MT2574/151

Time delay tends to destabilize any dynamical system. This is not true, however, in case of delayed oscillators, which serve as mechanical models for lots of surprising physical phenomena. Parametric excitation of oscillatory systems also leads to stability properties sometimes opposite to our physical sense. The combination of the two effects is a challenging task to predict nonlinear dynamic behaviour in these systems. Referring to the infinite dimensional nature of the dynamics of cutting subjected to regenerative effect, its nonlinear vibrations are often compared to the problem of turbulence in fluid mechanics.

In case of turning, the linear stability analysis of stationary cutting provides complicated, sometimes fractal-like stability charts in the space of the technological parameters (cutting speed, depth of cut and feed rate). Some experiments predicted the existence of unstable periodic motions around the stable stationary cutting already in the early 80Šs, but the corresponding subcritical co-dimension 1 and 2 Hopf bifurcations in turning processes have been shown analytically only recently. The description of the global dynamics of the cutting process ŚoutsideŠ the unstable limit cycles or unstable tori requires the analysis of the so-called self-interrupted cutting, when the time-intervals of the no-contacts between the tool and the workpiece are regulated by the system itself.

Milling is a kind of cutting where loss of contact between the teeth of the tool and the work-piece occurs typically in a periodic way. This leads to non-autonomous governing equations

similar to the damped, delayed Mathieu equation. The parametric excitation in the delay-differential equation yields secondary Hopf (or Neimark-Sacker) bifurcations, and also period doubling (or flip) bifurcations, when the cutting speed is high enough. The global nonlinear dynamics of turning and high-speed milling are compared as self-interrupted and parametrically interrupted cutting processes.

Analytical modeling of chatter stability using multi-dimensional approach. **Erhan Budak** (Sabanci University, Turkey) IC/MT2472/151

Chatter is one of the main problems in machining resulting in poor surface finish and low productivity. Stability models can be used to determine stable cutting conditions with higher productivity. Although majority of the machining systems involve muti dimensional dynamics, most of the stability models consider a single dimension in the formulation. This seminar willl give a brief overview of the multi dimensional models that we have developed for turning, boring and milling processes. The turning stability model considers the tool and part dynamics in two directions as well as insert nose radius. The model for milling involves stability analysis of time varying multi dimensional system which is solved analytically. Experimental results and industrial will be presented for different processes. Finally, methods for machine tool dynamics measurement and modeling will be discussed.

Surface errors for helical mills. **Dániel Bachrathy** (Budapest University of Technology and Economics, Hungary), Gabor Stepan (Budapest University of Technology and Economics, Hungary) IC/MT1083/151

Stability and surface location error are investigated numerically for milling operations with helical tool. A detailed mechanical model is derived that includes both surface regeneration and the helical teeth of the tool. The governing delay-differential equation is given in closed form and is analyzed by the semi-discretization method. The surface location error is predicted based on the forced motion of the tool for different axial depths of cut. The relationship of the spectrum of the cutting force and the surface properties is described. It is shown that the surface location error is varying periodically along the axial direction due to the helical teeth.

Phase-locked and quasi-periodic vibrations in a high-speed milling process. **Robert Szalai** (University of Bristol, UK) IC/MT2276/151

Milling processes are common in industry as they can achieve fast and high precision manufacturing. They are frequently used in the automotive and aerospace industry, where parts with difficult geometry are produced. Despite the efficiency these processes are not always reliable since they tend to exhibit unwanted vibrations due to disturbances. This stability loss is usually attributed to either the period doubling or the classical Hopf instabilities, which are subcritical. In this talk we focus on quasi-periodic and phase-locked periodic motions that arise at secondary Hopf bifurcations. Models of machining processes, due to the surface regeneration, are formulated as delay-differential equations. We introduce a method to compute quasi-periodic solutions as invariant tori in these models. These solutions are defined by a first order delayed partial differential equation, which is solved by a spectral collocation method. Using pseudo arclength continuation which keeps the rotation number fixed and follows the two technological parameters we determine phase locked regions in the stability chart.

Bifurcation in material flow during high-speed machining. **Timothy Burns** (National Institute of Standards and Technology, USA) IC/MT2793/151

A high-speed machining operation provides an interesting setting for the study of plastic flow under extreme conditions. In the thin primary shear region where cutting takes place, it is not uncommon, in alloys of interest in manufacturing, to have strains on the order of 1-10, strain rates on the order of 10^4 to 10^5 s^{-1}, and heating so rapid that the local workpiece temperature increases from ambient to a significant fraction of the melting temperature on the order of a tenth of a second or less. The thin metal strip, called a chip, which is removed during a machining operation, provides a record, i.e., a time series history, of the deformation that takes place during the cutting process. Examination under a microscope shows that chip structures can vary, depending upon the cutting conditions, from a fairly smooth case with little structure, called a continuous chip, to an extreme case with a highly periodic structure that results from repeated adiabatic shear band formation, called a shear-localized chip. In a series of papers with M.A. Davies over the past decade, ideas from nonlinear dynamics theory have been applied to model NIST experimental results on the complex evolution of the chip structure from continuous to shear-localized with increasing cutting speed. Recent improvements in high-speed micro-videography in infrared and visible wavelengths have enabled experimental measurements to be obtained at NIST of chip formation as it occurs in the plane strain setting of orthogonal cutting. New experimental results and attempts to model them from the point of view of nonlinear dynamics will be discussed.

Large-amplitude nonlinear vibration in regenerative turning model. **Zoltán Dombóvári** (Budapest University of Technology and Economics, Hungary), Richard Wilson (University of Bristol, UK), Gabor Stepan (Budapest University of Technology and Economics, Hungary) IC/MT1086/151

Self-excited nonlinear vibrations occurring in machining processes are investigated. Our treatment applies analytical and numerical techniques to a one degree of freedom but strongly nonlinear mechanical model of the turning process. This enables us to describe and analyse the highly nonlinear dynamics of the appearing periodic and more complicated motions. Using normal form calculations for the delay-differential equation model, we prove that the low-amplitude vibrations are unstable all along the stability boundaries due to the subcriticality of Hopf bifurcations. This means that self-excited vibrations of the machine tool may occur below the stability boundaries predicted by the linear theory. Zones of bi-stability are presented in the traditional stability lobe diagram.

Numerical tools for understanding chattering behaviour in non-smooth DDE models. **David Barton** (University of Bristol, UK) IC/MT2462/151

Cutting processes, such as turning or high-speed milling, often exhibit non-smooth behaviour in the form of chattering motion. Chattering is a self-excited instability where the machine tool repeatedly loses and re-establishes contact with the workpiece, causing degradation of the workpiece. Models of turning or milling that include the effects of chatter are frequently derived as systems of non-smooth delay differential equations (DDEs). However, numerical methods for the analysis of these systems are currently very limited. Often, only numerical simulation is possible.

In this talk we will demonstrate a new method for the numerical continuation of non-smooth solutions of DDEs, where the solutions are found via the solution of a multi-point boundary value problem. Numerical continuation allows a picture of the global dynamics to be built up, including any bifurcations and stability changes, and so increase our understanding of the model behaviour under parameter variations. This new method will be illustrated with the example of a regenerative turning model where chaotic chattering motion is caused by a non-smooth grazing bifurcation.

Harvesting nonlinear dynamic interactions for vibration enhanced drilling. **Marian Wiercigroch** (University of Aberdeen, UK) IC/MT3546/151

We will show how the nonlinear dynamic interactions can be used to enhance the material removal rate (MRR) and the accuracy of drilling brittle materials. First ultrasonic percussive drilling with diamond-coated tools [1] will be discussed where extensive theoretical and experimental studies conducted under laboratory conditions on rocks such as sandstone, limestone, granite and basalt, in order to investigate the applicability of this technique to downhole drilling. The experimental investigations showed that an introduction of high-frequency axial oscillations significantly improves MRR, which is strongly dependent on the static load has at least one maximum. These findings were confirmed theoretically using a simple drifting oscillator [2].

IC/MP623/015: Mathematics for steel manufacturing.

Organiser: Dietmar Hömberg (Weierstraß-Institut Berlin, Germany)
Co-organiser: Michael Wolff (Universität Bremen, Germany)

Steel is still the most important construction material in industrial societies. One reason is that one can change its physical properties by thermal treatment, due to solid solid phase transitions. This is utilized for industrial applications in the heat treatment of steel.

The goal of the minisymposium is to show how mathematics can contribute to a deeper understanding of the occuring phase transitions and how modern methods of optimal control of pdes can be utilized for a descent description of heat treatments.

The first part is focused on the continuum mechanical modelling of phase transitions in steel, its mathematical analysis and on the optimal control of thermomechanical phase transition models.

The second part is concerned with the mathematical analysis, efficient numerical simulation and optimal control of three different surface heat treatment processes: laser, induction and case hardening.

The third part deals with the welding of steel. Here the focus is on optimization of laser welding and the analysis of a joule heating problem related to resistance welding.

Analysis of a thermomechanical phase transition model. **Krzysztof Chełmiński** (Warsaw University of Technology, Poland) IC/MT2550/152

Subject of the talk is a macroscopic thermomechanical model of phase transitions in steel. Effects like transformation strain and transformation plasticity induced by the phase transitions are considered and used to formulate a consistent thermomechanical model.

The resulting system of state equations consists of a quasistatic momentum balance coupled with a nonlinear stress-strain relation, a nonlinear energy balance equation and a system of ordinary differential equations for the phase volume fractions.

We prove the existence of a unique weak solution using fixed-point arguments. A key issue is a regularity analysis for the mechanical subsystem to obtain continuity of the stress tensor. Finally, we depict some results of numerical simulations.

Analysis of a Joule-heating model related to resistance welding. **Francisco Ortegón Gallego** (Universidad de Cádiz, Spain), María Teresa González Montesinos (Universidad de Cádiz, Spain) IC/MT1473/152

The heat produced by an electrical current passing through a conductor device is governed by the so-called thermistor problem. This problem consists in a coupled system of nonlinear parabolic–elliptic equations, whose unknowns are the temperature inside the conductor, u, and the electrical potential, φ, namely

$$\begin{aligned} \frac{\partial u}{\partial t} - \nabla\cdot(a(u)\nabla u) &= \sigma(u)|\nabla\varphi|^2 && \text{in } \Omega_T = \Omega\times(0,T),\\ \nabla\cdot(\sigma(u)\nabla\varphi) &= 0 && \text{in } \Omega_T\\ u = 0,\quad \varphi &= \varphi_0 && \text{on } \Gamma_T = \partial\Omega\times(0,T),\\ u(\cdot,0) &= u_0 && \text{in } \Omega, \end{aligned}$$

where Ω, the domain occupied by the electrical device, is an open, bounded and smooth enough subset of $\mathbb{R}^N$, $N \geq 1$ and $T > 0$. The nonlinear source term $\sigma(u)|\nabla\varphi|^2$ is the Joule effect.

The purpose of this work is to establish the existence of a certain class of solutions to this system under certain weak assumptions on data. The fundamental obstacle in the resolution of this problem lies in the degenerate character of the parabolic equation ($a(0) = 0$, $a(s) > 0$ for all $s \neq 0$) and the non-uniformly elliptic character of the elliptic equation ($\sigma(s) > 0$ for all s,). In that case, the existence of weak solutions are not guaranteed, and we have to deal with another type of solutions, namely, capacity solutions. This situation covers those cases of practical interest, for instance, when $a(s)$ is given by the Wiedemann–Franz law, $a(s) = Ls\,\sigma(s)$ for some constant value $L > 0$, and with metallic conduction; that is, $\sigma(s) = \mathrm{O}(s^{-1})$ for $|s| \gg 1$.

Modelling, analysis and simulation of case hardening. **Lucia Panizzi** (Scuola Normale Superiore di Pisa, Italy) IC/MT1880/152

A mathematical model for the gas carburizing in steel is presented. Carbon is dissolved in the surface layer of a low-carbon steel part at a temperature sufficient to render the steel austenitic, followed by quenching to form a martensitic microstructure. We have a nonlinear evolution equation for the temperature, coupled with a nonlinear evolution equation for the carbon concentration, both coupled with two ordinary differential equations to describe the phase fractions. The coupling between the heat and the carbon diffusion part of the model is given through the temperature-dependent carbon diffusivity coefficient on the one hand and through the source term in the carbon equation on the other hand, depending implicitly on carbon and temperature through the phase fractions. We present mathematical results concerning the well-posedness of the model and finally present a simulation of the process using a finite element approximation.

IC/MP623/015: Mathematics for steel manufacturing. #2

(For abstract, see session #1 above.)

Optimal control of a thermo-mechanical model of phase transitions in steel. **Daniela Kern** (Weierstraß-Institut Berlin, Germany), Dietmar Hömberg (Weierstraß-Institut Berlin, Germany) IC/MT1740/152

We consider an optimal control problem concerning heat treatment of steel.

The mathematical model consists of the equations of thermoelasticity coupled to a system of rate laws accounting for the phase transition kinetics. For the coupling a mixture ansatz for the different thermal expansion coefficients is used. In contrast to classical thermoelasticity this leads to residual deformations whenever the resulting phase distribution at end-time is inhomogenous.

We show well-posedness of the mathematical model, investigate the optimal control problem and conclude with some numerical simulations.

Optimization of induction heat treatment process for steel parts . **Francois Bay** (Ecole des Mines de Paris, France) IC/MT3465/152

Induction heating is being increasingly used for heat treatment of steel parts. These processes aim mostly at achieving a certain level of hardness for the final part. Heat treatment processes often require aiming at a precise path in space and time for temperature evolution.

We shall present here a specific optimization procedure, coupled to a numerical model for induction heat treatment processes for steel parts.

The direct induction heating model [1] solves both Maxwell equations as well as the heat transfer equation, using a finite element-based space discretisation, which leads to a coupled system of equations for the electromagnetic and heat transfer computations. This coupled system provides the constraints of our optimization problem.

We use a conjugate gradient type method for minimizing the cost function. Once the descent direction has been computed, the descent-step is used to get the value of the cost function as small as possible through a parabolic interpolation algorithm.

The computation of the cost function sensitivity with respect to the control parameters is based on an optimal control approach. We define the Lagrangian of the problem. After some mathematical treatment of equations [2], we then get the adjoint thermal field and the adjoint electromagnetic field.

Results will be presented on heat treatment cases for which we aim at improving frequency, current density and inductor velocity.

Control of laser surface hardening . **Wolf Weiss** (Weierstraß-Institut Berlin, Germany) IC/MT1230/152

Several control strategies for the laser surface hardening of steel are discussed. The goal is to achieve a prescribed hardening depth avoiding surface melting. The mathematical model consists of a system of ODEs for the phase fractions coupled with the heat equation. The system is solved semi-implicitely using the finite element method. To obtain a uniform hardening depth the first attempt is to use PID control to achieve a constant temperature in the hot spot of the laser beam on the surface. However, the numerical results prove that this is not sufficient. The best strategy is to control the temperature close to the lower boundary of the hardening zone. Then one can compute the optimal temperature in the hot spot of the beam and use it as the set-point for the pyrometer control of the real process.

Constrained optimization of laser welding models. **Jonathan Montalvo Urquizo** (Universität Bremen, Germany), Alfred Schmidt (Universität Bremen, Germany) IC/MT1839/152

The laser welding process depends not only in the nature of the material to be welded, but also in diverse welding parameters like velocity, laser type and strength, etc. During the weld creation, the material pieces are exposed to high temperature changes in a very short period of time. This fast changes can result in high residual stress and consequently in mechanical disadvantages for the welded piece (e.g. hot cracks, loss of strength, etc.).

In order to reduce these disadvantages, the search for the best calibration of the welding parameters is of interest. We present a simplified model for laser welding simulation coupled with an optimization procedure to find some of the parameters that better suit to the aims of small residual stresses, narrow welds, high welding speeds and low laser power.

The optimization is based in a reflective trust region procedure for nonlinear constrained problems and the weld simulations are implemented in ALBERTA.

This talk reports the work done within the graduate school Scientific Computing in Engineering as a joint computational and experimental project between the *Zentrum für Technomathematik* and the *Bremer Institut für angewandte Strahltechnik*.

IC/MP209/153: Numerical methods for chemically reacting flows.

Organiser: Jeffrey Banks (Sandia National Laboratories, USA)
Co-organiser: John Shadid (Sandia National Laboratories, USA)
Co-organiser: Donald Schwendeman (Rensselaer Polytechnic Institute, USA)

Chemically reacting flows are important to many industrial applications. These applications are wide ranging and include convectively dominated flows such as detonation waves in high explosives, laminar and turbulent combustion systems, and diffusively dominated flows in devices such as chemical vapor deposition (CVD) reactors. Numerical methods for the simulation of such wide ranging phenomenon are necessarily quite different, but many of the underlying principles are common throughout. The goal of this mini-symposium is to bring together scientists working in these different fields and to provide a broad overview of numerical methods and simulation results for this wide range of combustion problems.

A posteriori *error estimation for flamelet models.* **Pascal Turbis** (Université de Montréal, Canada), Anne Bourlioux (Université de Montréal, Canada), Alexandre Ern (École Nationale des Ponts et Chaussées, France) IC/MT1936/153

Flamelets are asymptotic solutions for the full transport of reactants in the limit of very thin flames. The objective here is to estimate the modelling errors when flamelets are used as turbulent closure, including cases with moderately thin flames. The challenge is to perform such estimation on the go, at a computational cost not exceeding significantly that of using flamelet libraries. We show this can be accomplished using the *a posteriori* error estimators introduced by Braack and Ern. So-called adjoint flamelet libraries are used to estimate errors, with application to model selection within a hierarchy of models, or parameter optimization for a given model.

An overview of the application of fully-coupled Newton-Krylov solution methods for FE simulation of transport/reaction systems. **John Shadid** (Sandia National Laboratories, USA), Roger Pawlowski (Sandia National Laboratories, USA), Paul Lin (Sandia National Laboratories, USA), Andrew Salinger (Sandia National Laboratories, USA) IC/MT2575/153

The need to simulate fluid flow systems with thermal energy and mass species transport, along with non-equilibrium chemical reaction is common in advanced technology applications. These systems are strongly coupled, highly nonlinear and characterized by multiple physical phenomena that span a very large range of length and time scales. These characteristics make the scalable, robust, accurate, and efficient computational solution of these systems extremely challenging.

In this presentation I will overview a number of the important solution methods that our research group has applied in the large-scale simulation of transport/reaction systems. The solution methods that we employ include, fully-implicit time integration, direct-to-steady-state solution methods, continuation, bifurcation, and optimization techniques. The resulting large sparse linear systems that are generated by these methods are solved by the application of parallel preconditioned Newton-Krylov methods. The preconditioners include additive Schwarz domain decomposition (DD) and multi-level preconditioners.

To demonstrate the capability of these methods I will present simulation and performance results for a range of representative low heat release and high heat release transport / reaction simulations.

A fully-implicit FE formulation for plasma/transport-reaction and resistive magneto-hydrodynamic systems. **Roger Pawlowski** (Sandia National Laboratories, USA), John Shadid (Sandia National Laboratories, USA), Jeffrey Banks (Sandia National Laboratories, USA), Pavel Bochev (Sandia National Laboratories, USA) IC/MT2493/153

Plasma systems with strong electro-magnetic effects and chemical species transport and reaction occur frequently in nature and are critical for many important technological applications. Examples include stellar interiors, gaseous nebula, the earth's magnetoshpere, and Tokamak and Z-pinch physics. These systems are described by a set of partial differential equations that conserve momentum, mass, charge, and energy for chemical species along with Maxwell's equations for the electric and magnetic fields. The resulting equations are strongly coupled, highly nonlinear, and span a large range of time and length scales, making the scalable, robust, and accurate solution of such systems extermely challenging.

In this presentation, we will discuss the initial development of a new PTR/MHD formulation based on unstructured finite element methods and fully implicit time intergration techniques. Our initial implementation employs a variational multi-scale stabilized finite element solver that implicitly enforces div B = 0 by use of a vector potential formulation. We will discuss numerical performance, accuracy, and scalability. Example problems will include fast magnetic reconnection and DC plasma arc jets.

Simulation of lean pre-mixed turbulent combustion. **John Bell** (Lawrence Berkeley National Laboratory, USA) IC/MT1482/153

Both environmental and economic concerns have generated significant interest in developing new fuel-flexible combustion systems that can employ alternative fuels such as hydrogen, ethanol or syngas. Effective utilization of these fuels requires combustion devices that can operate cleanly and efficiently over a broad range of fuels and fuel mixtures. Lean-premixed systems have the potential for meeting these requirements; they operate at high efficiency and have low NOx emissions due to reduced burnt gas temperatures. Although traditional scientific approaches based on theory and laboratory experiment have played essential roles in developing our current understanding of premixed combustion, they are unable to meet the challenges of designing fuel-flexible lean, premixed combustion devices. Computation, with its ability to deal with complexity and its unlimited access to data, has the potential for addressing these challenges. Realizing this potential requires the ability to perform high fidelity simulations of turbulent lean premixed flames under realistic conditions. Estimates of the computational cost of such simulations suggest that naive simulation approaches would be prohibitively expensive. In this talk, we examine the specialized mathematical structure of combustion problems and discuss approaches to

simulation that exploit this structure. Using these ideas we can reduce computational cost by three to four orders of magnitude, making it possible to perform high-fidelity simulations of realistic laboratory flames. We will illustrate this methodology by considering several configurations to illustrate the methodology and discuss how this type of simulation is changing the way researchers study combustion.

Detonation evolution and structure for a model of reactive two-phase flow. **Donald Schwendeman** (Rensselaer Polytechnic Institute, USA), Ashwani Kapila (Rensselaer Polytechnic Institute, USA) IC/MT1710/153

A two-phase model of heterogeneous explosives is examined computationally by a new numerical approach that is a modification of the standard Godunov scheme. The approach generates well-resolved and accurate solutions using adaptive mesh refinement, and treats rationally the nozzling terms that render the otherwise hyperbolic model incapable of a conservative representation. A broad range of the parameter space is considered and two possible structures of steady, planar detonations are identified, along with subregions of the parameter space where they exist. The transient processes subsequent to impact by a low-speed piston are discussed, and these show the transition from a compaction wave to one or the other of the two steady detonation waves. Two-dimensional evolution for problems of detonation diffraction are also discussed.

Simulations of compliantly confined, shock-desensitized high explosives. **Jeffrey Banks** (Sandia National Laboratories, USA) IC/MT1731/153

High explosive charges are used in many industrial and laboratory settings. The detonation mechanism involved in such charges are quite complex and many questions involved in their modeling and simulation remain open. Here we present a model for shock desensitization of a high explosive and place this in the context of a multi-material flow solver. This solver is a high-resolution Godunov method which operates on a collection of overset grids and uses adaptive mesh refinement (AMR) to capture small scale features within the flow. The multi-material capability is used to model the compliant confinement of a high-explosive charge by air, brass, or some other relevant material. The effects of this confinement then couple with the shock desensitization model within the explosive. The result is a simulation tool which can more accurately reproduce experimental evidence. We present a number of examples including detonation diffraction around corners and detonation failure in converging rate sticks. These results are compared to results obtained using rigid confinement and/or without any shock desensitization model.

IC/MP148/154: Multiscale problems in materials sciences.

Organiser: Christof Eck (Universität Erlangen–Nürnberg, Germany)
Co-organiser: Peter Knabner (Universität Erlangen–Nürnberg, Germany)

Micro- and nano-structures are an indispensable tool in the engineering of new advanced materials. They arise in the production process of materials (as e.g., the production of metals by casting processes), or the production of semiconductor devices by epitaxy, and they are relevant for many important phenomena; e.g., the shape memory effect in shape memory alloys, the evolution of plastic deformations by slip lines, and magnetism.

Up-to-now, the research on micro- and nanostructures has mainly adressed models on a single scale. On one hand, there are completely avaraged or homogenized models for processes having a technologically relevant scale; where the properties of micro- or nanostructures enter only in a very heuristic way via macroscopic constitutive laws. On the other hand, there are specialized models for the evolution of single microstructure elements (as e.g., single dendrites in casting processes), single or few slip lines in plastic deformation, single or few molecules in MD simulations. These techniques are typically applicable to very small length and/or time scales only.

In the recent years, new analytical and computational techniques arose that promise to bridge large scale differences and therefore enable the simulation of micro- and nanostructures within length scales of technical relevance. Prominent examples are the heterogeneous multiscale method, and the multi-scale FEM, as well as advances in more traditional areas as homogenization.

The aim of the minisymposium is to present the latest development concerning the coupling of different models and different scales and to discuss and compare the different mathematical and computational concepts.

The interplay of thermodynamics and kinetics in crystal growth. **Axel Voigt** (FZ caesar, Germany) IC/MT983/154

We discuss a meanfield model for a one-dimensional step in which a detailed atomistic structure is considered. The model consists of a diffusion equation for an edge-adatom density on the evolving step, a convection equation for a kink density on the step and a velocity law for the evolution of the step. The equations are coupled through atomistc processes, such as attachment/detachment of edge-adatoms at kinks, nucleation/destroying of kink-dimers and so on. The resulting multiscale model requires besides the step stiffness only atomistic hopping rates as parameters. The stiffness is computed from atomitic models. We introduce a finite element discretization and show results for thermodynamic smooting, kinetic smoothing and an instability resulting from a kink Ehrlich-Schwoebel barrier.

Two-scale modeling of adsorption processes at structured surfaces. **Heike Emmerich** (RWTH Aachen, Germany), Maria Radke de Cuba (RWTH Aachen, Germany), Sibylle Gemming (RWTH Aachen, Germany), Gudrun Schuerer (RWTH Aachen, Germany) IC/MT1856/154

We investigate the adsorption behavior of oxalate on a structured glass surface at several temperatures. For this purpose a hybrid scheme was developed which combines a two-dimensional anisotropic Ising model mapped on a lattice gas model with a phase-field model for vicinal surface growth. The microstructure dynamics on the vicinal surface are calculated using the phase-field method which is based on the classical Burton-Cabrera-Frank (BCF) theory. The molecular behavior of individual adatoms is resolved by the Monte-Carlo generated dynamics of the Ising model which include an incoming flux, diffusion and desorption. The corresponding constants measured by Monte-Carlo simulation are put into the phase-field part. During Monte-Carlo simulation the particles form clusters or attach to the step edges. To each cluster a binding energy is assigned which is inherited from the Ising Hamiltonian. Depending on this energy it is decided if the corresponding cluster becomes part of the surface after the transformation to the phase-field part. Therefore the atomic and micro-scale dynamics influence each other dynamically during surface evolution by an Arrhenius-like reaction path. The corresponding energy scales are derived by first principle calculations. Several growth modes are distinguished in the present scheme characterized by morphology and roughness which decreases with increasing temperature.

A finite-difference approach for concurrent multiscale computations in solids. **Shaoqiang Tang** (Peking University, PR China) IC/MT1802/154

In concurrent multiscale computations for solids, the atomistic computations capture detailed dynamics in a selected MD subdomain, while the macroscopic computations are performed in the vast surrounding region. Almost all existing multiscale methods adopt finite element approaches in the MC region, and usually use an approximated Hamiltonian for deriving the FEM schemes. A handshaking region is usually designed to reduce interfacial reflections. The approximation errors may not be easy to analyze and hard to control.

In this talk, we propose a class of velocity interfacial conditions and formulate a finite difference approach for multiscale computations of crystalline solids with relatively strong nonlinearity and large deformation [2]. With a coarse grid cast over the whole domain, we compute the coarse scale dynamics using finite difference schemes derived by a matching differential operator method [1], together with a reassignment by averaging the fine scale solution for the atomistic subdomain. In a coarse scale time step, we adopt a linear wave approximation around the interface, with the coefficients determined from the coarse grid solution. Based on this approximation, we develop a class of velocity interfacial conditions with different order of accuracy. The interfacial conditions are straightforward to formulate, easy to implement, and effective for reflection reduction in crystalline solids with strong nonlinearity. Multiscale simulations in one and two space dimensions demonstrate the accuracy, the robustness and the efficiency for the proposed approach.

A two-scale model for liquid phase epitaxy. **Christof Eck** (Universität Erlangen–Nürnberg, Germany) IC/MT1299/154

Liquid phase epitaxy is a special technique to grow thin solid layers from a liquid solution. The main mechanism is the deposition of atoms in monoatomar layers. Often epitaxy leads to microstructures of the phase interface that may be of technical relevance. We study a model for liquid phase epitaxy that consists of differential equations for the transport of fluid and solute in the liquid phase and a Burton Cabrera Frank (BCF) model for the growth of the solid layer. In order to derive a model that is suitable for a very small scale of the microstructures, we apply homogenization techniques and construct a two-scale model that couples macroscopic equations for the transport processes in the fluid to microscopic evolution equations for the solid phase. For a phase field approximation of the BCF model, the solvability of the two-scale model is analyzed and an estimate for the model error is derived. A possible extension of the model that incorporates the effect of elastic deformations in the solid phase will be given.

Minimizing the stray-field energy in micromagnetics subject to a convexified point-wise constraint. **Carsten Carstensen** (Department of Mathematics Humboldt-Universität, Germany), Dirk Praetorius (TU Wien, Austria) IC/MT3326/154

The large body limit in the Landau–Lifshitz equations of micromagnetics yields a macroscopic model without exchange energy and with convexified side conditions for the macroscopic magnetisation vectors. Its Euler Lagrange equations **(*P*)** read: Given a magnetic body $\Omega \subseteq \mathbb{R}^d$, $d = 2, 3$, an exterior field $\mathbf{f} \in L_2(\Omega)^d$, and the convexified anisotropy density $\phi^{**} : \mathbb{R}^d \to \mathbb{R}_{\geq 0}$, find a magnetization $\mathbf{m} \in L_2(\Omega)^d$ and a Lagrange multiplier $\lambda \in L_2(\Omega)$ such that a.e. in Ω

$$\nabla u + D\phi^{**}(\mathbf{m}) + \lambda \mathbf{m} = \mathbf{f},\ |\mathbf{m}| \leq 1, \quad \lambda \geq 0,\ \lambda(1 - |\mathbf{m}|) = 0.$$

The potential $u \in H^1_{\ell oc}(\mathbb{R}^d)$ solves the (Maxwell) equations

$$\nabla u \in L_2(\mathbb{R}^d)^d \text{ and } \operatorname{div}(-\nabla u + \mathbf{m}) = 0 \text{ in } \mathcal{D}'(\mathbb{R}^d)$$

in the entire space. It therefore appears natural to recast the associated far field energy into an integral operator $\mathcal{L}$ which maps $\mathbf{m}$ to the corresponding potential u.

The proposed numerical scheme involves the operator $\mathcal{L}$ and replaces the pointwise side-condition $|\mathbf{m}| \leq 1$ by a penalization strategy. Given a triangulation $\mathcal{T}$, the induced space of piecewise constant functions $P_0(\mathcal{T})$ on Ω, and a penalization parameter $\varepsilon > 0$, the discrete penalized problem **($P_{\varepsilon,h}$)** reads: Find $\mathbf{m}_h \in P_0(\mathcal{T})^d$ such that for all $\boldsymbol{\nu}_h \in P_0(\mathcal{T})^d$

$$\langle \nabla(\mathcal{L}\mathbf{m}_h) + D\phi^{**}(\mathbf{m}_h) + \lambda_h \mathbf{m}_h ; \boldsymbol{\nu}_h \rangle_{L_2(\Omega)} = \langle \mathbf{f} ; \boldsymbol{\nu}_h \rangle_{L_2(\Omega)}$$

with $\lambda_h := \varepsilon^{-1} \dfrac{\max\{0, |\mathbf{m}_h| - 1\}}{|\mathbf{m}_h|} \in P_0(\mathcal{T})$.

Numerical aspects addressed in the presentation include the integration of the matrices with quadrature rules and hierarchical matrices as well as a priori and a posteriori error control with a reliability-efficiency gap and adaptive mesh-design.

Discrete-to-continuum limit of the magnetic force between rigid bodies dependent upon their distance. **Anja Schlömerkemper** (Max-Planck-Institut Leipzig, Germany), Bernd Schmidt (California Institute of Technology, USA) IC/MT1677/154

In earlier work[1,2], the discrete-to-continuum limit of the magnetic force between two bodies being in contact was studied and a new lattice dependent term was found. In order to obtain a better understanding of magnetic forces at small distances between rigid magnetic bodies, we consider an analogous problem: we study the magnetic force between two bodies which are assumed to be a distance apart on the lattice scale but in contact on the scale of the continuum. In the continuum limit we obtain an additional term which depends on the distance between the two bodies on the lattice scale. We discuss analytical properties of this additional term.

[1] Schlömerkemper, A.; Mathematical derivation of the continuum limit of the magnetic force between two parts of a rigid crystalline material. *Arch. Rational Mech. Anal.* **176** (2005), pp.227–269.

The effect of defects on the motion of a martensitic phase boundary. **Patrick Dondl** (California Institute of Technology, USA) IC/MT2634/154

We study the role of defects in the quasistatic evolution of a martensitic phase boundary. Martensitic phase transformations involve a change in shape of the underlying crystal, and thus the propagation of the phase boundary is accompanied by an evolving mechanical stress and strain field. This gives rise to a nonlocal free boundary problem, one where the evolution of the free boundary is coupled to a partial differential equation. Often, real materials contain defects which can potentially pin the interface and contribute to the hysteresis, and understanding this is the goal of this work. We present a mathematical model and a proof of existence in the sense of sets of finite perimeter. We then present numerical simulations and analysis of both the fully nonlocal problem as well as a linearized version, and draw conclusions on the role of defects on hysteresis.

A phase field model in electro-wetting and related phenomena. **Marco Fontelos** (Universidad Autónoma de Madrid, Spain), Christof Eck (Universität Erlangen–Nürnberg, Germany), Günther Grün (Universität Erlangen–Nürnberg, Germany) IC/MT4588/154

Electro-wetting phenomena involve films of viscous fluids over solid substrates, in the present of electric fields and with moving electric charges. This yields a system of equations for the charge density, electrostatic potential and velocity field together with forces due to surface tension and electrostatic repulsion between charges of the same sign. We develop a description of the fluid interface through a phase field satisfying a convective Cahn–Hilliard equation and present a thermodynamically consistent deduction of the model consisting of Stokes equations and advection-diffusion equations for the motion of charges coupled with it. We provide a mathematical proof of global existence of weak solutions to the model and discuss the implementation of numerical methods to solve it.

IC/MP39/154: Simulation in nano-technology and bio-mathematics.

Organiser: Leela Rakesh (Central Michigan University, USA)

Understanding the mathematical rigorness is very crucial for any minute details in nanotechnology and its social impact. The symposium on nanomathematics is to support the emerging nanotechnology and nanoscience revolution through an interdisciplinary mathematical modeling and simulation applied to the understanding of biology, chemistry and physics of nanomaterials. We will discuss some of the recent advances and publications by myself and colleagues working closely with Chemist, Doctors, Engineers, and Industrialists in this area.

The US Department of Energy has identified a key potential research target for future development of the field: "lack of development of theory, analytical techniques, and modeling and simulation tools (TAMS)". A collaborative effort by some selected universities in US and industries would address these issues by developing a coherent, yet multidisciplinary, program in the fundamentals of TAMS at the nanoscale and in the problems of linking behaviour on the small scale to the large scale. In addition to being truly active in the worldwide scene of nanoscience and nanotechnology education and research, it can potentially have an important, and possibly crucial, impact on the development of related commercial enterprises in the US. For example, the electronics industry will not risk deploying billions of devices based on molecular electronics, unless they are thoroughly understood and manufacturing processes are made predictable and controllable.

This symposium will contribute to the basic understanding of fluid dynamics and better analytical techniques, thus enabling the better design, modeling, predictability, efficiency and control of systems that involve fluids and will also address innovative uses of fluids in materials development, manufacturing, biotechnology, nanotechnology, clinical diagnostics and drug delivery. Another example related to the impact of nanotechnologies on the fluid and molecular dynamics, are highlighted by micro fluidics and the hybrid continuum molecular emergence as an enabling technology, and hence used in practical fluid and molecular dynamics problems from laminar flow control in aerospace applications to problems in medicine, thermodynamics and production engineering. For example,

(i) Complex Fluids: Rheology, instability, physics of polymer solutions, DNA, Molecular Dynamics simulations;
(ii) Micro- Nano- Bio- Fluid Mechanics: Micro fluidics, biomedical micro devices, Atomic force microscopy, Nuclear magnetic resonance, effects of nanoscale inclusions on rheological properties, flows in biomedical assistive devices, multiscale modeling of biological flow processes.

Nanoscale effects are also crucially important in the development of new materials such as the complex composites used in the aerospace industry, biomedical engineering for prosthesis to heart valves, Organometallic drug encapsulation for various cancer treatment and the revolution in communications technology promised by photonic optical fibers. Because TAMS has been identified as an enabler of nanoscience and technology, it could potentially have a great impact on the development of commercial enterprises in this area. Indeed, the uniqueness of this proposed activity could actually encourage and attract potential startup companies to the region.

Packing cylinders on a cylinder with contact constraints. **Eric Goold** (Central Michigan University, USA) IC/MT3563/0

The problem of cylinder packing is investigated. The specific problem is to determine the maximum number of congruent cylinders that can be packed around a core cylinder of arbitrary dimensions. The constraint is that their circular face must keep in contact with the core cylinder and there may be no overlapping. Only right circular cylinders are considered. Mathematically, a lower and upper bound is determined. A quantitative result is also found using a modified genetic algorithm. The algorithm was found to reproduce the published results for the top and bottom circular faces of the core which reduces to the problem of packing congruent circles within a circle. Several other algorithms are discussed along with their computational speeds.

Two-level atoms: normal-form approach. **Raghu Gompa** (Jackson State University, USA) IC/MT3700/0

Perturbation theory that is based on normal form techniques is studied in the context of Schrödinger initial value problem associated with two-level atoms to arrive at approximations that deviate in norm from the exact solution by a term of order e2t.

Differential geometry and the red blood-cell. **Wescott Vayo** (University of Toledo, USA) IC/MT3795/0

The usual mathematical expressions for the shape of the red blood cell, whether in rectangular or polar coordinates, are very complicated and difficult to use analytically. The main difficulty that remains unsolved is that related to the complexity of the mathematical expressions describing quantities of geometric interest. We have found that by using parametric equations and hyperbolic functions to describe the cell functioning are much easier. The usual differential geometric concepts of a normal red blood cell can be adopted to find interesting new formulas by incorporating ideas like FickŠs Law, etc.

Experimental and computational characterization of nanoscale dendritic organoplatinum antitumor drugs. **Bob Howell** (Central Michigan University, USA), Leela Rakesh (Central Michigan University, USA) IC/MT3858/0

Organo-platinum compounds exhibit broad antitumor activity. Cisplatin [cis-dichlorodiammine platinum (II)] is the most prominent of this family and is currently the most prescribed cancer drug. It is widely used for the treatment of human testicular, ovarian, bladder, head and neck carcinomas. However, it is an extremely toxic compound and side effects such as nephrotoxicity and myelotoxicity are major drawbacks for its use in clinical applications. A way to combat the side effects associated with the administration of platinum drugs would be to generate a prodrug conjugate that, when present in the extracellular fluid, would slowly release active platinum species at a level below the threshold for side effects. Traditionally, linear hydrophilic polymers have been examined for potential application as carrier platforms for these drugs. The advent of dendrimers, which are highly branched macromolecules with precisely controlled nanoscale size, shape and end-group functionality, has provided an excellent opportunity to design and formulate novel multivalent time-release drug systems. A program to do this is well-underway. For example, treatment of a generation 4.5 (carboxylate surface) poly(amidoamine) [PAMAM] dendrimer with diaquo(1,2-diaminocyclohexene) platinum(II) generates a nanoparticle with forty platinum moieties attached at the surface [D. Fan, B.A. Howell and L. Rakesh, Polym. Mater. Sci. Eng., 93, 946 (2005); B. A. Howell, D. Fan and Leela Rakesh, J. Therm. Anal. Cal., 85, 17 (2006)]. This polymer-drug conjugate displays a very good release profile for the platinum species. Under physiological conditions about 80

Modeling and simulation of the evolution of crystal morphologies with anisotropic surface free-energy. **Wen Zhang** (Oakland University, USA), Ian Gladwell (Southern Methodist University, USA) IC/MT3165/0

We present a mathematical model and computational method for the evolution of crystal surface by surface diffusion with anisotropic surface free energy. Employing the model and computation we study the evolution path of a single crystal to equilibrium and the morphologies of periodic surfaces. We examine examples of simple cubic crystals with different levels of anisotropic surface free energies and different initial configurations. The simulation results are compared with the atomic force microscopy studies of grain surfaces in annealing processes such as thermal grain-boundary grooving. The evolution is governed by a nonlinear 4th order time dependent partial differential equation. We find that with a mildly anisotropic surface free energy, the crystal morphology is smooth and evolves to a unique equilibrium crystal shape (ECS). In the cases of grain boundary grooving, the groove profiles are self-similar in the evolution and follow a power law with the exponent 1/4. However, the shapes of these profiles have striking differences from those developed under isotropic surface free energy. With a severely anisotropic surface free energy, depending on the initial crystal configuration and surface free energy, edges, corners and faceting by hill-and-valley structures on crystal surface may occur. A large planar surface facet in the ECS can be obtained, arbitrarily closely, using smooth anisotropic surface free energies. And a polyhedron Wulff shape is the limit of Wulff ECS with smooth anisotropic surface free energies. In general, the ECS reached in computation depends on the initial surface configuration. This dependence becomes more evident as the anisotropy becomes more severe but is less likely to occur for 3D crystals than for 2D crystals. By enforcing a corner condition in the cases of 2D crystals, we obtain better stability in the evolution, which leads to the ECS having lower total surface free energies than those obtained without satisfying the corner condition.

Molecular-dynamics simulation of PAMAM dendrimer–fullerene conjugates. **Leela Rakesh** (Central Michigan University, USA) IC/MT3220/0

We describe an attempts at preparing polyamidoamine (PAMAM) dendrimer-fullerene (C60) conjugates, using increasing generations (G0 to G4) of PAMAM and C60 in pyridine. Based on the synthesis of the PAMAM (G4)-C60 conjugate in a molar ratio of 1:30, Jensen etal had hypothesized that two surface amine group interact with one fullerene molecule to form the conjugates. Computer simulation study on the same system was to found to be excellent agreement based on the energy minimization process. The same computational techniques were then used to determine the energy-minimized structure of the remainder of the conjugates, and compare their solubility behaviors in pyridine along with (G4)-C60. The findings allow for a better understanding of structure-property relationships of these nano-hybrid materials, through investigation of the molecular shape, radial distribution function, and radius of gyration. Our findings reported herein may lead to improved syntheses of fullerene-dendrimer conjugates of various sizes as well as further understandings of their nanoscopic structures and topographical influences.

Complexation of PPI dendrimers with Zn(II) *ions.* **MInghui Chai** (Central Michigan University, USA) IC/MT3363/0

PPI [poly(propyleneimine)] dendrimers are multidentate ligands which can chelate with metal ions to form complexes using the primary and tertiary amino groups in their structures. In this study we used NMR spectroscopy to probe the preferred binding sites of different generation (G1–G3) PPI dendrimers with Zn(II) ions. AFM (atomic force microscopy) was also used to detect the sizes of these dendrimer-metal complexes as well as to explore their surface morphology. The results from the NMR study clearly show that Zn(II) ions prefer to chelate with the primary and tertiary amino groups on the exterior of the dendrimer. For a 1:8 ratio of the PPI–3/Zn(II) complex, interestingly all eleven unique protons can be well resolved in the 2D COSY spectrum. Based on the resolved 1H resonances, the 13C NMR resonances can be unambiguously assigned using 2D 1H13C HMQC experiments. In addition, the AFM study shows that the surface of the PPI–Zn(II) complexes is *harder* than the surface of the PPI dendrimers, which also indicates that the coordination between the dendrimer and the Zn(II) ion mainly occurs on the exterior of the dendrimer. Furthermore, the results from molecular dynamics simulations and ab initio calculations on the complexes of a different generation PPI dendrimers with Zn(II) ions are consistent with the conclusions from NMR studies. Therefore this work provides an insightful view of where and how metal ions bind with the dendrimers.

Skin, a smart hydrogel, and its nano-technological mimics. **Anja Mueller** (Central Michigan University, USA) IC/MT3481/0

Skin is the ultimate smart material that can turn chemical energy into mechanical energy and heat. It fulfills a variety of vital functions for the body under various operating conditions and it respond to changing environments. It is a hydrogel with multiple components, regulated by only a few general regulation and transport mechanisms. In this talk the structure and function of major components of skin as a hydrogel are presented, as well as the basic regulation mechanism. This information can be used for numerical simulation of the steady-state deformation and regulation of a smart hydrogel under an external field. Nanotechnological mimics of some of these structures and regulation mechanisms are then compared with skin itself. Such investigation will lead to the discussion of skin scaffolds for burn victims that include the majority of functions of skin, allowing for improved healing of extensive burns.

IC/MP215/154: Multiscale porous media: applications.

Organiser: Mary Wheeler (University of Texas at Austin, USA)
Co-organiser: Hector Klie (University of Texas at Austin, USA)
Co-organiser: Robert Scheichl (University of Bath, UK)

Multiphase flow, transport, and reaction in porous media have important applications in petroleum reservoir engineering and in groundwater flow. These often involve multiphase multiphysics processes across multiple temporal and spatial scales whose discretisation leads to large highly ill-conditioned linear systems. This minisymposium showcases recent advances in applications, with emphasis on reservoir simulation, multiphase flow, and transport of contaminants in heterogeneous media. It is linked to the two other minisymposia: “Multiscale porous media: discretizations” and “Multiscale porous media: solvers”.

Multiscale time stepping for contaminant transport in an heterogenous medium. **Jean Roberts** (INRIA Rocquencourt, France), Jérôme Jaffré (INRIA Rocquencourt, France), Estelle Marchand (INRIA Rocquencourt, France), Amel Sboui (INRIA Rocquencourt, France) IC/MT2931/154

The problem of simulating flow and transport of radionuclides in a neighborhood of an underground nuclear waste storage site is very complex due in large part to the widely varying scales involved in the physical model. The storage site itself, the source of the contaminants, is heterogeneous and of complex geometry. The far field, the area surrounding the storage site is of much larger dimension, roughly 50 kilometers by 50 kilometers in horizontal extent and 500 meters in depth and is also very heterogeneous. The physical properties of the various geological layers differ greatly yielding permeability, diffusion, and dispersion coefficients that vary over several orders of magnitude. Thus the flow and transport in the different layers take place on different time scales. Further, since the half life of some of the radionuclides is quite long the simulation corresponds to a time duration of several hundred thousands of years.

In this presentation we show how subdomain time stepping may be implemented in order to use time steps appropriate to the time scales of the processes taking place in the different layers. The domain is divided into nonoverlapping subdomains respecting the geological layers. Different size time steps are used for advection and diffusion-dispersion and different size time steps are used in different layers. The diffusion-dispersion time steps are implicit and at time steps in which the global problem must be solved, domain decomposition is used. Numerical experiments will be presented.

Multiscale finite-element methods and adaptive coarsening: moving towards Earth Model reservoir simulation. **Jørg Aarnes** (SINTEF, Norway) IC/MT1101/154

Reservoir simulators normally take as input coarsened geological models derived through an upscaling process. However, partly due to grid-limitations, upscaled models generally fail to capture important subscale features, such as narrow high-flow channels and barriers, properly. The generation of simulation grids is also usually non-automated, and generally the most time-consuming part of the upscaling process. Due to limitations of upscaling, there is now a growing demand for Earth Model reservoir simulators capable of taking geostatistical models provided by geologists as input. If simulations are not to be performed on the initial grid, then all grid coarsening strategies should be fully automated, and designed to preserve the important subscale features in the geostatistical model. We propose combining a multiscale mixed/mimetic finite element method (MsMFEM) for computation of pressure and velocities with an automated, weakly constrained, adaptive grid coarsening strategy.

The MsMFEM provides accurate and detailed velocity fields at the cost of a flow-based upscaling methods, also for models with complex grid geometries, and puts almost no constraints on the coarsened grid used to discretize the pressure equation. As the grid constraints associated with upscaling is primarily related to discretization of the pressure equation, MsMFEM alleviates one of the main limitations of upscaling, and readily allows for automated coarsening strategies. In addition, by providing mass conservative velocity fields on an underlying fine grid, e.g., the geostatistical model, MsMFEM allows the use of grids for computing phase transport that are adaptive to fine-scale features. In our coarsening approach, the only grid constraints are that grid cells should be connected, have at least some minimum volume, and less total flow than some threshold. Results will be presented to demonstrate the general performance of the combined methodology.

Multiscale finite-volume method for three-phase flow in porous media. **Seong Lee** (Chevron ETC, USA), Christian Wolfsteiner (Chevron ETC, USA), Hamdi Tchelepi (Stanford University, USA) IC/MT1178/154

The multiscale finite volume (MSFV) method is extended to the standard black oil formulation for three phase, compressible flow (oil-gas-water) with gravity/capillarity. The mass transfer between oil and gas phases is described by solution gas. An operator splitting is employed to decompose the pressure equation into elliptic part, buoyancy/capillary force dominant part, and inhomogeneous part with source/sink (wells) and accumulation. Flow and transport equations are decoupled and solved sequentially. An accurate coarse grid operator is derived for the flow equation (pressure and velocity) and a local fine grid solution is reconstructed via basis functions. In addition, adaptive computation is extensively implemented for numerical efficiency. The MSFV method of black oil formulation allows us to study a large class of practical problems. The numerical efficiency of MSFV is analyzed and the robustness and computational efficiency of the MSFV is demonstrated by simulating large, heterogeneous reservoir models.

A multiscale method for parameter estimation in reservoir simulation. **Adolfo Rodriguez** (University of Texas at Austin, USA), Hector Klie (University of Texas at Austin, USA), Mary Wheeler (University of Texas at Austin, USA) IC/MT1616/154

The main objective of oil parameter estimation (history matching) is to find model parameters such that numerical predictions agree with past observed reservoir response. Once parameters are estimated, the reservoir model is employed to simulate future reservoir performance on a wide range of exploitation scenarios. However, history matching is a very challenging problem due to the ill-posedness and high computational cost involved in estimating hundreds of thousands to millions of parameters in conventional reservoir settings. These parameters are generally given by permeability values at each block of the spatially discretized domain. To effectively alleviate this problem, we introduce a multiscale approach in such a way that the parameter estimation is first performed at a coarse resolution scale and the results are then downscaled to be used as an improved initial guess for the original scale. This is accomplished by applying the Singular Value Decomposition (SVD) to the prior permeability field so that it is expressed as a weighted summation of an eigenimage basis. The SVD expansion ensures compatibility with previous geological nterpretations while gives flexibility to adjust the fine scale details of the model. An upscaling procedure based on wavelets is applied to the expansion in order to obtain a coarse-scale expansion whose weights are determined by a history matching procedure. Once the weights are estimated, they are downscaled and used along the original eigenimages to create a new initial guess for the fine-scale problem. The procedure can be repeated for a number of intermediate scales in order to facilitate the downscaling procedure. In order to capture finer details of the original parameter space, we release the SVD parameterization at the finer scale. In this way, the estimation is able to include permeability features at each grid-block. The above procedure is illustrated through a number of numerical experiments on reality-based datasets.

IC/MP652/155: Inverse problems and applications I: mathematical techniques for imaging.

Organiser: Oliver Dorn (Universidad Carlos III de Madrid, Spain)
Co-organiser: Manuchehr Soleimani (University of Manchester, UK)

New mathematical techniques are emerging in a variety of real world applications, for example in the broad area of imaging and inverse problems. The need for combining novel mathematical concepts with powerful and flexible numerical algorithms is ever increasing in this area. In the session, four specialists will present novel mathematical approaches for important real world problems from medical, industrial and geophysical tomography, such as diffuse optical tomography, microwave medical imaging, thermal conductivity and heat capacity tomography, and the characterization of nonconventional petroleum reservoirs.

A Newton–Krylov method for optical tomography. **Simon Arridge** (University College London, UK) IC/MT2912/155

Several problems in medical imaging can be characterised as parameter identification problems, and can be solved for example by an output least squares method. Newton schemes are amongst the most popular, and often involve construction of large dense Jacobian matrices that can be prohibitive to store. In this talk we present an efficient method for Gauss–Newton and full-Newton methods that do not involve the storage of the Jacobian. The method is shown applied to the recovery of absorption and scattering cross-sections in optical tomography.

Level-set techniques for microwave medical imaging. **Natalia Irishina** (Universidad Carlos III de Madrid, Spain), Oliver Dorn (Universidad Carlos III de Madrid, Spain), Miguel Moscoso (Universidad Carlos III de Madrid, Spain) IC/MT2904/155

Recently there has been increased interest in the use of microwaves for the early detection of breast cancer. The high contrast of electromagnetic parameters of malignant tissue with respect to healthy tissue makes this technique a very promising alternative to the more traditional technique of X-ray imaging which suffers from low contrast images and a potential health risk due to the ionizing nature of the probing radiation. However, there are still several mathematical problems to be resolved before microwave data can be used for the early diagnosis of breast cancer. In order to reliably detect and characterize a tumor in its early stage of development it is necessary to reconstruct from the data basic information about its location, its size, its shape and its electromagnetic parameter values. For example, an indication whether a tumor is benign or malign is given by the irregularity of its surface. Also the electromagnetic parameter values of the tumor can give important information about its nature. In our contribution we will present a novel technique for detecting and characterizing small tumors in the breast from microwave data which uses a level set representation of its shape. In particular, we focus on the simultaneous characterization of the shape, size and location of the tumor together with its electromagnetic properties. We present numerical examples in 2D in order to discuss the performance of our new technique in realistic situations.

Reconstruction of thermal conductivity and heat capacity using a tomographic approach. **Ville Kolehmainen** (Kuopion Yliopisto, Finland) IC/MT3019/155

We consider the estimation of the volumetric heat capacity and the thermal conductivity as distributed parameters. The measurement scheme consists of sequentially heating the boundary of the object in different source locations and measuring the induced temperature evolutions in different measurement locations on the boundary. The estimation of the distributions of volumetric heat capacity and thermal conductivity based on these boundary data is an ill-posed inverse boundary value problem. We propose an approach which is based on transient data on the boundary and the modelling of the unknown coefficients as Markov random fields. We propose a statistical (Bayesian) approach for this estimation problem. The intended applications are non-destructive retrieval of defects as well as the estimation of macroscopic characteristics of novel materials. We evaluate the proposed approach by a numerical simulation.

Shape-based techniques for an inverse two-phase flow problem in reservoir characterization. **Rossmary Villegas** (Universidad Carlos III de Madrid, Spain), Oliver Dorn (Universidad Carlos III de Madrid, Spain), Miguel Moscoso (Universidad Carlos III de Madrid, Spain), Manuel Kindelan (Universidad Carlos III de Madrid, Spain) IC/MT3006/155

Reservoir characterization is an important component nowadays in the petroleum industry for enhancing hydrocarbon production. Mathematically an inverse problem for multiphase flow in porous media needs to be solved for reconstructing physical fluid flow properties (for example permeability) of the reservoir. When a reservoir contains more than one rock-type (lithofacies), then standard inversion techniques are inappropriate since they yield oversmoothed reconstructions of the interfaces between regions of different rock-types. We propose in this talk a novel technique which is able to reconstruct simultaneously the boundaries of regions of different rock-types and the smoothly varying internal permeability structure inside of these regions. For describing the different lithofacies, a level set technique is employed. The reconstruction of the regions is done by an evolution of the level set function describing the individual lithofacies in a descent direction of a given cost functional. The internal permeability profiles are recovered by additional evolution laws for these quantities. Here we use two different strategies, a pixel-based representation and a parameterized representation of the permeability profile inside of each region. Using an efficient adjoint scheme, the calculation of descent directions for the shapes and the internal permeability profiles requires only one direct and one adjoint two-phase flow simulation in each iteration. Numerical results are presented which show that our technique is able to recover simultaneously in a stable and efficient way different regions and internal permeability profiles from two-phase flow data for realistic situations in 2D.

IC/MP176/155: Mathematical challenges in medical and industrial imaging, I and II.

Organiser: Richard Kowar (Universität Innsbruck, Austria)
Co-organiser: Markus Haltmeier (Universität Innsbruck, Austria)

Computer aided non-invasive medical imaging and non-destructive industrial testing of materials can be improved by either enhancing currently available data or by developing new imaging modalities. In these two minisymposia we present both, novel modalities and novel mathematical algorithms. We cover the three main aspects of imaging, namely data acquisition, modeling and reconstruction theory. However, our minisymposia will focus on mathematical reconstruction theory, which is often the key for improving imaging quality and the success of a special application in industry and medicine.

The first minisymposium presents various applications of mathematical image reconstruction theory involving *wave phenomena* and exploiting *phase information*. It starts with a talk about the application of a new non-iterative fully three-dimensional imaging technique based on the *sampling* or *factorization method* to improve the quality of metal detectors. The second talk is about a direct inversion method for the wave equation, based on *time reversal*, with various applications such as thermoacoustic CT in heterogeneous media, underwater communication or lithotripsy (a medical technique to destroy kidney stones). The last two talks are concerned with the modeling, data acquisition and with novel imaging reconstruction methods in *phase contrast microscopy* and *schlieren tomography*.

The second minisymposium is entirely devoted to *thermoacoustic computed tomography* (CT), also called photoacoustic or optoacoustic CT. Thermoacoustic CT has the potential to become a major imaging method for non-invasive medical diagnosis. Its physical origin is the generation of acoustic waves by optical or thermal excitation. However, the key to its success is the development of proper reconstruction algorithms, involving the stable solution of problems of integral geometry (the theory of recovering of a function from its integrals over certain manifolds). The first talk in this minisymposium gives an overview over various modalities of data acquisition in thermoacoustic CT. In the remaining talks of the first minisymposium mathematical models and novel fast reconstruction algorithms are presented.

Sampling methods for low-frequency electromagnetic imaging. **Bastian Gebauer** (RICAM Linz, Austria), Martin Hanke (Universität Mainz, Germany), Christoph Schneider (Universität Mainz, Germany) IC/MT1653/155

We consider the problem of detecting objects by electromagnetic imaging; i.e., by applying time-harmonic surface currents on an electric device and measuring the backscattered electromagnetic field. Numerical studies show promising results for new non-iterative reconstruction techniques known as linear sampling methods. Using a low-frequency approach we give a theoretical justification for these methods and discuss the consequences of divergence-free conditions.

A direct method for the numerical time-reversal of waves in a heterogeneous medium. **Christian Clason** (TU München, Germany) IC/MT1769/155

We consider the problem of time reversal in a heterogeneous medium as the inverse problem of determining the solution of a wave equation with spatially varying coefficients from lateral Cauchy data. This problem occurs in several applications in the area of medical imaging and non-destructive testing.

Using the method of quasi-reversibility, the original ill-posed problem is replaced with a boundary value problem for a fourth order partial differential equation. We find a weak H^2 solution of this problem and show that it is a well-posed elliptic problem. Error estimates and convergence of the approximation follow from exact observability estimates for the wave equation, which are proven using a Carleman estimate. We derive a numerical scheme for the solution of the quasi-reversibility problem by a B-spline Galerkin method, for which we give error estimates.

Finally, we present numerical results supporting the robustness of this method for the reconstruction of the wave field from lateral Cauchy data, where we also consider the case of data given only on a part of the boundary.

Phase-contrast measurement techniques: some aspects about phase microscopy and Schlieren imaging. **Bettina Heise** (Universität Linz, Austria), Bernd Arminger (Universität Linz, Austria) IC/MT1667/155

Phase contrast microscopy (PCM), differential interference contrast microscopy (DIC) and Schlieren imaging belong to the traditional techniques for visualization of transparent objects which can be described by their phase map. The first two methods have found their usual application in cell biology, whereas Schlieren Imaging can be used in visualization of flows in fluid dynamic processes or of pressure fields. Although these methods possess high spatial resolution, the challenging task is to extract quantitative results from the images. For DIC imaging an approximation of the phase map can be obtained by deconvolution or by line integration methods using different shear directions. In quantitative phase microscopy (QPM) three differently focused images are recorded and the phase map can be calculated.
In contrast, the approach used in holographic interferometry is to record several images with defined phase shifts introduced e.g. by a piezoelectric transducer (PZT) or electro-optically by a spatial light modulator and to perform a trigonometric reconstruction to obtain quantitative values.

3D reconstruction of transducer pressure fields from Schlieren data. **Richard Kowar** (Universität Innsbruck, Austria) IC/MT1247/155

In order to ensure safety and optimal performance of medical ultrasound transducers it is necessary to measure the acoustic pressure fields of transducers. For the estimation of such pressure fields we use light intensity data that is obtained by a Schlierensystem. Schlieren data corresponds mathematically to squared x-ray tomographic data. Acoustic pressure fields attain positive and negative values, but only the square of the line integrals are provided by the Schlieren system. Therefore the signs of the line integrals are not known, and Schlieren data cannot be reduced to data of classical X–ray CT. For the numerical estimation of pressure fields we used the loping Landweber-Kaczmarz method.

IC/MP176/155: Mathematical challenges in medical and industrial imaging, I and II. #2

Organiser: Richard Kowar (Universität Innsbruck, Austria)
Co-organiser: Markus Haltmeier (Universität Innsbruck, Austria)

(For abstract, see session #1 above.)

Thermo-acoustic tomography: effects of ultrasound-pulse softening on reconstructed images. **Sarah Patch** (University of Wisconsin, Milwaukee, USA) IC/MT1327/155

Thermoacoustic computerized tomography (TCT) is a hybrid imaging technique exploiting the thermoacoustic effect. TCT has many parallels with xray CT, including frequency dependent attenuation of the measured signal. However, the nature of these attenuation phenomena is nearly opposite: xray beams Şharden,Ť whereas ultrasound pulses Şsoften.Ť Analytic formulae for a attenuated TCT pulses generated by a homogeneous spherical inclusion immersed in soft biological tissue and also in highly attenuating fluids are presented. Resulting artifacts in reconstructed xray CT and TCT images are compared and contrasted.

New reconstruction formulas and algorithms for problems of thermo-acoustic tomography. **Leonid Kunyansky** (University of Arizona, USA) IC/MT2546/155

The problem of image reconstruction in the thermoacioustic tomography is equivalent to the inversion of the spherical mean Radon transform. In other words, the unknown function is reconstructed from a family of its spherical integrals or means. The centers of integration spheres usually lie on a closed surface surrounding the object (the support of the sought function). Explicit inversion formulas are known for the case when this surface is a sphere. We present a series solution of the reconstruction problem, valid for several other surfaces of practical importance (such as, for example, surface of a cube or of a finite cylinder). For the case of the cubic measuring surface we also develop a fast reconstruction algorithm. The use of this technique accelerates the computation by a factor of several hundred and reduces reconstruction from hours to several seconds.

Comparison of different scanning geometries for photoacoustic tomography using line detectors. **Robert Nuster** (Universität Graz, Austria), Guenther Paltauf (TU Graz, Austria), Markus Haltmeier (Universität Innsbruck, Austria), Peter Burgholzer (Upper Austrian Research) IC/MT1849/155

Photoacoustic tomography is an emerging procedure for imaging of small biological samples. The combination of optical contrast and acoustical resolution of photoacoustic imaging is the advantage in comparison to pure optical and acoustical imaging.

The current method to realise photoacoustic tomography is to use arrays of ultrasound transducers or single detectors scanning around the object to record the acoustic signals excited by illumination of the sample with short laser pulses. An important factor limiting the image resolution is the finite size of the detectors. In an effort to partly overcome this limitation we propose to use detectors that are larger than the object and integrate the incoming acoustic wave over their volume. This approach requires special reconstruction algorithms. If the detector is a plane scanning around the object the recorded set of acoustic signals corresponds to the three-dimensional Radon transform of the initial pressure distribution in the object. In this case an image can be reconstructed with the standard inverse Radon transform.

In this study we investigate signal collection procedures and image reconstruction algorithms that are designed for detectors having the shape of a line with a length exceeding the size of the object. Recent experiments, using a scan of the line shaped detector only in one direction, show that the image is blurred in this direction. This undesirable effect can be limited by using two scanning directions perpendicular to each other to record the missing data. The resolution of the image is only limited by the width of the line and the temporal resolution of the detector.

Limited-angle inversion of the circular Radon transform. **Markus Haltmeier** (Universität Innsbruck, Austria) IC/MT2761/155

In this talk we study the recovering of a function from its circular Radon transform, or equivaently from its integrals over circles. This is the main problem that arises in photo-/thermoacoustic tomography with integrating line detectors. Recently exact inversion formulas have been found for full angle data where the center set is a circle enclosing the unknown function. However, in many practical applications, such as in breast cancer detection with photo-/thermoacoustic tomography, the center set does not enclose the unknown function. Theoretically, certain features of the object can be recovered stably. However, no stable direct algorithm for inverting such data is known. In this talk we compare iterative methods with data continuation methods for limited-angle inversion.

IC/MP75/155: Variational methods for real-world problems.

Organiser: Abul Hasan Siddiqi (King Fahd University, Saudi Arabia)
Co-organiser: Martin Brokate (TU München, Germany)
Co-organiser: Pammy Manchanda (Guru Nanak Dev University, India)

Variational methods have played a vital role in understanding properly various real world problems. Variational inequalities and inverse problems are two themes which have attracted attention of a large number of researchers in different disciplines. The main objective of the minisymposium is to discuss certain current trends concerning variational inequalities and inverse problems.

Models for plasticity with variably-shaped yield surfaces. **Martin Brokate** (TU München, Germany) IC/MT3493/155

Standard constitutive models in plasticity like isotropic or kinematic hardening involve yield surfaces which are not constant in stress space, but their degrees of freedom are either translation or enlargement. In this talk we discuss mathematical results which apply also to yield surfaces which, in dependence on the loading history, change their shape in a rather general manner.

On relaxed viscosity iterative methods for variational inequalities in Banach spaces. **Qamrul Hasan Ansari** (King Fahd University, Saudi Arabia), Lu-Chuan Ceng (Shanghai Normal University, PR China), Jen-Chih Yao (National Sun Yat-sen University, Taiwan) IC/MT1644/155

Let $\tilde{J}$ be a commutative family of non-expansive self-mappings on a nonempty closed convex subset C of a reflexive Banach space X such that the set of common fixed points is nonempty. In this paper, we suggest and analyze a relaxed viscosity iterative method for a commutative family of nonexpansive self-mappings on C. We also prove that the sequence of approximate solutions generated by the proposed method converges strongly to a solution of a variational inequality. Our relaxed viscosity iterative method is the extension and variant form of the original viscosity iterative method. Results proved in this paper may be viewed as an improvement and generalization of the previously known results in the literature.

Fitting TAR(1)-models to Shepard data. **Torsten Lindström** (University of Kalmar, Sweden) IC/MT3862/155

This paper addresses some problems regarding two approaches commonly used in population dynamics. The first one is the mechanistic approach starting from assumed mechanisms (Metz and Diekmann, 1986). It formulates models based on these mechanisms and makes predictions regarding the long-run population dynamics predicted when these mechanisms really govern the dynamics. The other approach starts from collected data and aims at the best possible short term dynamics usually by training the model to predict the patterns present in the data. Such methods (Hastie and Tibshirani, 1990) usually penalize nonlinearities in the models fitted to the data and if the correct model is nonlinear, also the correct model is penalized.

In the former approach bounded populations usually mean nonlinear models meaning that we are in a situation where we do not expect that these methods confirm each other unless large amounts of data are available. This is usually not the case in population dynamics. The former approach has the advantage over the second that it has the potential to predict dynamical patterns not present in the data. The problem is that the mechanisms assumed are never confirmed to be the governing ones unless the two approaches can be matched and we shall deal with theoretical problems arising when matching those two approaches.

We demonstrate the following results:

(1) We recall the bifurcation diagram of non-negative Schwartzian derivative maps used for the study of population cycles in Stenseth, Chan, Framstad, and Tong (1998) and Lindström and Thunberg (2006).
(2) A nonlinear Sheperd (1982) model is used for generating nonlinear data and the above models are fitted to these data. We show that the dynamics of the fitted models do not in general conform with the dynamical patterns of the Sheperd (1982) models.
(3) We also fit the nonlinear Ricker (1954) model to the same data showing that fitting a false nonlinear model to the given data produce even worse correspondences between original dynamics and fitted dynamics than in the former case. Nonlinear data-fitting can thus, not remedy the problems reported here even if they in principle would have the potential to follow the dynamics of the original model quite precisely.
(4) Finally, we fit Multivariate Adaptive Regression Spline (MARS)-models (Friedman, 1991) models having possibilities to recover most periods and dynamical patterns in the original data but detect switching phenomena already at low periods and low noise level. In these switching windows, the Sheperd model may display periodic behaviour whereas the fitted MARS-model displays non-periodic behaviour.

One additional problem is we do not have any information regarding the uniqueness of the periodic attractors of the MARS models. Such results exist for TAR(1)-models (Lindström and Thunberg, 2006).

On the uniform decay in an integro-differential elastic equation. **Messaoudi Salim** (King Fahd University, Saudi Arabia) IC/MT2877/155

In this work, we consider a second-order problem:

$$\begin{cases} u_{tt} - \sum_{i,j=1}^{n} \frac{\partial}{\partial x_j}(a_{ij}(x)\frac{\partial u}{\partial x_i}) + \int_0^t g(t-\tau)\sum_{i,j=1}^{n} \frac{\partial}{\partial x_j}(a_{ij}(x)\frac{\partial u}{\partial x_i})(\tau)d\tau = 0, & \text{holds within } \Omega\times(0,\infty) \\ u(x,t) = 0, & \text{for } x \in \partial\Omega,\ t \geq 0 \\ u(x,0) = u_0(x), u_t(x,0) = u_1(x), & \text{for } x \in \Omega \end{cases}$$

This type of problem models the deformation in an elastic material of memory type.

Under suitable conditions on g, we establish a uniform decay. Precisely, we show that the decay is exponential if g decays exponentially and the decay is polynomial if g decays in a polynomial fashion. This work generalizes the decay result, proved earlier for wave equations with integral term, to the above problem.

Analysis of the relationship between the ENSO and sea-level changes. **Zafer Aslan** (Istanbul Aydın University, Turkey), Z. Can (Istanbul Aydın University, Turkey), O. Oguz (Istanbul Aydın University, Turkey) IC/MT5039/155

The relationship between ENSO with ONI and sea-level (SL) changes are analyzed to define the role of ELNINO3.4 on sea level variations around Turkey and Indian coasts by using monthly sea level time series at 25 sites. There are positive correlation between SL and ENSO and ONI (warm and cold episodes) based on a threshold of +/- 0.5°C for the Oceanic Niño Index (ONI) based on the 1971–2000 base period. For historical purposes cold and warm episodes are defined when the threshold is met for a minimum of 5 consecutive over-lapping seasons. Different techniques have been used to define El Niño event. The most common ones are the Southern Oscillation Index (SOI) and the Niño regions. The Niño regions refer the SST anomalies in defined parts of the Tropical Pacific. There is sufficient evidence on the relation between time series analysis of Sea Level values and ELNINO indices. In northern coastal part of Turkey, the role of positive effect is high. At the western coastal part of Turkey the relation between ELNINO indices and SL is negative. This relation can also be interpreted by applying 1-D wavelet and continuous wavelet packets on data. Cross-correlation maps at regional scale for Turkey and India have been presented.

High-index differential-algebraic equations and application to trajectory optimization. **Soumyendu Raha** (Indian Institute of Science Bangalore) IC/MT924/155

Trajectory optimization problems arise in robotics and design of nominal guidance and control for aero-space vehicles. The present study is in the context of re-entry to landing trajectory optimization of reusable space vehicles. The trajectory problem is a high index differential-algebraic equations (DAE) model resulting from rigid body dynamics of the vehicle constrained by heat flux, loading and landing speed requirements. This kind of DAE models are common for many other areas of engineering and the computational and numerical methods studied can be extended to those problems without loss of generality. The present study develops a damped discretization for the method of transcription solution to the problem. The effect of damping has been studied in the context of convergence and stability of the iterates generated by the transcription method in a sequential quadratic programming (SQP) like non-linear programming (NLP) solver. This computational study has been contrasted with index reduction approaches. Numerical examples are given to illustrate the results.

Existence and iterative approximation of solutions of some systems of variational-like inequalities and inclusions. **Syed Khan** (Aligarh Muslim University, India), Kaleem Kazmi (Aligarh Muslim University, India) IC/MT2864/155

Variational inequality theory introduced by Stampacchia and Fichera independently, in early sixties in potential theory and mechanics, respectively, constitutes a significant extension of variational principles. The development of variational inequality theory can be viewed as the simultaneous pursuit of two different lines of research. On the one hand, it reveals the fundamental facts on the qualitative behavior of solutions to important classes of problems. On the other hands, it enables us to develop highly efficient and powerful numerical methods to solve, for example, obstacle, unilateral, free and moving boundary value problems. One of the most important and interesting problem in the theory of variational inequalities is the development of numerical methods which provide an efficient and implementable algorithm for solving variational inequalities and its generalizations. Some of such methods are projection methods and its various forms; proximal-point mapping method, linear approximation, descent and Newton's methods, and the methods based on auxiliary principle technique. In 1985, Pang [Math. Prog. **31** (1985) 206-219] showed that a variety of equilibrium models, for example, the traffic equilibrium problem, the spatial equilibrium problem, the Nash equilibrium problem and the general equilibrium programming problem can be uniformly modelled as a variational inequality defined on the product sets. He decomposed the original variational inequality into a system of variational inequalities and discuss the convergence of method of decomposition for system of variational inequalities. Later, it was noticed that variational inequality over product sets and the system of variational inequalities both are equivalent. Since then many authors studied the existence theory of various classes of system of variational inequalities by exploiting fixed-point theorems and minimax theorems. On the other hand, only a few iterative algorithms have been constructed for approximating the solution of system of variational inequalities.We remark that most of the work on approximate solvability of variational (-like) inclusions and systems of variational (-like) inequalities has been done in the setting of *Hilbert spaces*.
vspace.20cm

Motivated by the recent research work in this directions, we consider some systems of variational (-like) inequalities and inclusions; develop the iterative algorithms for finding the approximate solutions and discuss their convergence criteria. Further, we study the sensitivity analysis of solution of the system of variational inclusions. The techniques and results presented here improve the corresponding techniques and results for the variational inequalities and inclusions in the literature.

System of variational inclusions Let, for $i = 1,2$, E_i is q_i-uniformly smooth Banach space with norm $\|.\|_i$.Let $g_i, A_i, B_i : E_i \to E_i$ be nonlinear mappings; let $F : E_1 \times E_2 \to E_1, G : E_1 \times E_2 \to E_2$ be two nonlinear mappings, and let $M : E_1 \to 2^{E_1}$, $N : E_2 \to 2^{E_2}$ be m_i-accretive, respectively, such that $g_i(x) \in domainM_i(.)$, for all $x \in E_i$. We consider the following system of general variational inclusions (SGVI): Find $(x,y) \in E_1 \times E_2$ such that

$$\begin{cases} F(A_1(x), A_2(y)) + M(g_1(x)) \ni \theta_1; \\ G(B_1(x), B_2(y)) + N(g_2(y)) \ni \theta_2, \end{cases} \tag{4.1}$$

where θ_1 and θ_2 are zero vectors of E_1 and E_2 respectively.Using proximal-point mapping technique, we prove the existence and uniqueness of solution and suggest a Mann type perturbed iterative algorithm for SVLI. Furthermore, we discuss the convergence criteria and stability of Mann type perturbed iterative algorithm. Further, we consider a system of parametric general variational inclusions (in short SPGVI) corresponding to SGVI and discuss the continuity of the solution.

System of variational-like inequalities Let $I = \{1,2\}$ be an index set and for each $i \in I$, let H_i be a real Hilbert space whose inner product and norm are denoted by $\langle .,. \rangle_i$ and $||.||_i$, respectively. For each $i \in I$, let $F_i : H_1 \times H_2 \to H_i$, $\eta_i : H_i \times H_i \to H_i$, $g_i : H_i \to A_i$, $g_i : H_i \to H_i$, $B_i : H_i \to H_i$ be nonlinear mappings, then we consider the following system of generalized variational-like inequality problems (SGVLIP):

Find $(x,y) \in H_1 \times H_2$ such that

$$\langle F_1(A_1(x), A_2(y)), \eta_1(g_1(v_1), g_1(x)) \rangle_1 + b_1(x, g_1(v_1)) - b_1(x, g_1(x)) \geq 0, \ \forall v_1 \in \tag{2.1}$$

$$\langle F_2(B_1(x), B_2(y)), \eta_2(g_2(v_2), g_2(y)) \rangle_2 + b_2(y, g_2(v_2)) - b_2(y, g_2(y)) \geq 0, \ \forall v_2 \in \tag{2.2}$$

where for each $i \in I$, the bifunction $b_i : H_i \times H_i \to R$, which is not necessarily differentiable, satisfies some suitable conditions. We prove an existence theorem for auxiliary problems of SGVLIP. Further, by exploiting this theorem, an algorithm for the SGVLIP is constructed. Furthermore, we prove the existence of a unique solution of SGVLIP and discuss the convergence analysis of the algorithm. **Remark:**

(i) Using the approaches given here, one can extend Theorems presented here to the systems of n-variational-like inclusions and inequalities.
(ii) It is of further research interest to extend the approaches discussed in this talk for iterative approximation of solutions of the systems of variational-like inclusions and inequalities, involving set-valued mappings.

IC/MP654/155: Inverse problems and applications II: soft-field tomography in engineering.

Organiser: Manuchehr Soleimani (University of Manchester, UK)
Co-organiser: Oliver Dorn (Universidad Carlos III de Madrid, Spain)

Mathematical techniques play a growing role in many engineering applications. Often novel mathematical concepts are needed in order to meet the rapidly evolving requirements of the practitioners. One prominent example of such a research area is soft-field tomography. In the session, four experts will present examples of such novel mathematical techniques emerging in this exciting research area. Examples are atomic force spectroscopy, tomographic image reconstruction and dynamic process tomography.

Force spectroscopy in atomic-force microscopy. **Nick Polydorides** (University of Cyprus) IC/MT1358/0

This work is motivated by the inverse force spectroscopy problem in atomic force microscopy. In the formulation of the forward problem we consider the Euler-Bernoulli model for flexural vibration of an AFM cantilevered beam of finite length, under the influence of a distributed load force. Our aim is to show that the profile of the load force can be inferred by sampling the vertical displacement of the vibrating beam. Accounting for the appropriate boundary and initial conditions, we derive the GreenŠs function of the system and cast the solution of the problem in an integral equation form. In this context, we approach the inverse problem using *a priori* information about the plausible deformations of the cantilever beam.

Challenges in mathematics for electrical capacitance tomography. **Wuqiang Yang** (University of Manchester, UK) IC/MT1497/0

There are two major problems to be solved with electrical capacitance tomography (ECT): the forward problem and the inverse problem. Because ECT is based on soft field sensing and the relationship between capacitance and permittivity is non-linear, it is difficult to solve the forward problem analytically. While a finite element method (FEM) or finite difference method (FDM) may be used, depending on the geometry of a sensor, to solve the forward problem numerically, a major challenge remains to find a solution accurately and quickly. Usually, the number of capacitance measurements in a data set is much less than the number of pixels in an image. Obviously, the solution to the inverse problem is under-determined. Furthermore, the inverse matrix is ill-posed and ill-conditioned. This presents a major challenge in mathematics. This paper will discuss the above challenges. Some image reconstruction algorithms will be discussed in detail, such as the relaxation factor, semi-convergence and the convergence speed. While iterative algorithms are considered by mathematicians and feedback control by control engineers independently, it seems that the concept and terminology used in the two fields are corresponding to each other. It would be interesting to see how control system design can benefit iterative image reconstruction. As 3D ECT is being investigated at several research institutions, this paper will discuss some specific challenges with 3D ECT, including measurement strategy, a finite volume method (FVM), the condition number of sensitivity matrix, and demanding on computation and memory.

Adaptive importance sampling in particle filter based dynamic process tomography . **Daniel Watzenig** (TU Graz, Austria), Gerald Steiner (TU Graz, Austria), Markus Brandner (TU Graz, Austria) IC/MT1737/0

The estimation of cross-sectional material distributions from non-stationary sparse tomographic measurement data is a demanding class of ill-posed inverse problems. Electrical Capacitance Tomography (ECT) is a well-established modality that aims at monitoring and controlling dynamic industrial processes arising e.g. in pneumatic conveying or heterogeneous flow fields. Due to its low cost, good dynamic behavior and operability under harsh environmental conditions, ECT has gained importance over the last decade. By measuring the capacitances between certain electrodes that are arranged around the periphery, the permittivity distribution inside closed objects can be spatially resolved.

In this paper, the main focus is on the robust estimation of time-dependent process metrics like void fraction and fill level given uncertain measurements. The underlying inverse problem is formulated in a Bayesian inferential framework, by accurately modeling the forward map, specifying a prior distribution for the cross-sectional material distribution, and characterizing the statistics of the measurement noise, to give a

posterior distribution for relevant process parameters conditioned on measured data. The forward map is numerically implemented using the Finite Element Method (FEM). Transitions between different material phases are described by means of a Fourier contour model of second order implying a geometric regularization yielding smooth shapes in the image space. Sequential Monte Carlo filtering – particle filtering – is applied to solve the non-stationary inverse ECT problem. Consequently, the inverse ECT problem is recast as a state estimation problem. In order to improve the filter performance adaptive importance sampling based on the residual error information is proposed. This modification of the filter algorithm allows for fast detection of time-varying material inclusions that may appear in different regions of the cross-sectional area of pipes. Based on a significant change in the residual error, particles are scattered in regions where the inter-electrode capacitances have changed indicating a variation of the electric properties in that area. Furthermore, the issue of recognizing an empty pipe is addressed by monitoring the error variance of the all particles. The posterior variability of estimated process metrics is evaluated to give statements on the parameter confidence. Different experiments are performed in order to show the robustness of the Bayesian filtering approach to solve the non-stationary inverse problem given measured electrical capacitance data.

Subspace-based reconstruction algorithms for the inverse problem of electrical impedance tomography. **Ronny Hoffmann** (Vrije Universiteit Brussels, Belgium), Bart Truyen (Vrije Universiteit Brussels, Belgium), Jan Cornelis (Vrije Universiteit Brussels, Belgium) IC/MT1941/0

We present a subspace based, structure preserving solution method for the problem of Electrical Impedance Tomography, where the conductivity inside a simply connected 2-dimensional domain is sought from noisy and incomplete boundary data. Unlike conventional output-least squares algorithms that can be regarded as minimizing a certain error norm, solutions are recovered here as the minimizers of a closely related residual norm problem. An iterative solution scheme is shown to lead to a sequence of sparse matrix subproblems, with conditioning far more favorable than typically observed in output-least squares. We find that these sparse subproblems demonstrate a particular form of displacement structure that can be further elaborated to finally arrive upon an efficient computational implementation. In this contribution we introduce the structured problem formulation, outline the algorithmic approach taken, and summarize some of its numerical properties.

IC/MP1076/015: Optimal control of industrial applications modelled by DAEs and P(D)AEs.

Organiser: Kurt Chudej (Universität Bayreuth, Germany)
Co-organiser: Matthias Gerdts (University of Birmingham, UK)

Optimization and optimal control of huge realistic models of industrial applications are challenges for applied mathematiciens. Although the applications come from different fields like container cranes, cars and power plants, the mathematical problems are very similiar. New tailored approaches and generalized theory are necessary to cope with the huge complexities of the models.

Optimal control, simulation and model reduction of large PDAE-systems. **Armin Rund** (Universität Bayreuth, Germany), Hans Josef Pesch (Universität Bayreuth, Germany), Kurt Chudej (Universität Bayreuth, Germany) IC/MT2331/159

Molten carbonate fuel cells (MCFC) are especially well suited for stationary power plants if their process heat is used to increase their efficiency. MCFCs will become soon competitive compared with traditional power plants.

The dynamic behaviour of MCFCs can be modelled mathematically by a hierarchy of systems of partial differential algebraic equations (PDAE) in 1D or 2D. Integral terms appear and the nonlinear boundary conditions are given partly by a DAE system.

These large PDAE systems of dimension between roughly 10 and 30 equations are discretized by the method of lines, yielding huge dimensional DAEs. In order to enable real time control of the system model reduction techniques are needed. We will present new computationally expensive numerical results of (sub)optimal control during load changes for a 2D dynamical MCFC model.

Optimal control of an industrial robot by a non-smooth Newton's method. **Martin Kunkel** (Universität Hamburg, Germany) IC/MT2156/159

We investigate a nonsmooth Newton's method for the numerical solution of discretized optimal control problems subject to pure state constraints and mixed control-state constraints. The infinite dimensional problem is discretized by application of a general one-step method to the differential equation. By use of the Fischer-Burmeister function the first order necessary conditions for the discretized problem are transformed into an equivalent nonlinear and nonsmooth equation. This nonlinear and nonsmooth equation is solved by a globally convergent nonsmooth Newton's method. Numerical examples for the optimal control of a robot conclude the article.

Switching-times optimization for bang–bang and singular controls in bioprocess engineering. **Georg Vossen** (Universität Bremen, Germany) IC/MT2393/159

We will study optimal control problems with the control variable appearing linearly. The optimal control function in such problems often contains both bang-bang and singular arcs, i.e., it takes values at the boundary, resp., inside the control domain. These control problems occur in many industrial application fields such as mechanics, biotechnologies and medical sciences. A method of transforming the problem into a finite-dimensional optimization problem will be presented. This so-called induced optimization problem involves the (finitely many) switching times, all free initial state values and the free final time. On the one hand, this method is a strong tool for solving high-dimensional optimal control problems. On the other hand, one is able to check second-order sufficient conditions (SSC) for this problem in a numerically efficient way. Additionally, it is often interesting to investigate the influence of certain pertubations into the system. This parameter sensitivity can also easily be computed in the induced problem. We will show that the SSC test and the sensitivity analysis can be applied on the basis of only first order variations of the state trajectory which can be derived by solving simple linear initial value problems. All results will be illustrated with a model of the optimal control of a fed-batch fermentation process.

Optimal control of constrained time lag systems: necessary conditions and numerical treatment. **Laurenz Göllmann** (Westfälische Wilhelms-Universität Münster, Germany), Helmut Maurer (Universität Münster, Germany), Daniela Kern (Weierstraß-Institut Berlin, Germany) IC/MT3277/159

In this talk we consider retarded optimal control problems with constant delays in state and control variables under mixed control-state inequality constraints.

First order necessary optimality conditions in the form of Pontryagin's minimum principle are presented and discussed as well as numerical methods based upon discretization techniques and nonlinear programming. The minimum principle for the considered problem class leads to a boundary value problem which is retarded in the state dynamics and advanced in the costate dynamics.

It is shown that the Lagrange multipliers associated with the programming problem provide a consistent discretization of the advanced adjoint equation for the delayed control problem.

Finally, the theory and the proposed numerical method are illustrated by an example from chemical engineering. We discuss the optimal control of a continuous stirred chemical tank reactor system (CSTR) in order to apply the proposed algorithm and to compare the computed results with the theory. Due to significant transportation times given by the flow rate of the chemical reactants some state and control variables enter the dynamic equations of the CSTR with a delay.

Analyzing securitization processes using simulation methods. **Marcin Wierzbicki** (Military University of Technology, Poland), Radoslaw Pytlak (Military University of Technology, Poland) IC/CT2862/015

The aim of this paper is to describe the securitization process and factors which affect it. At the beginning we present shortly the purpose and key elements of securitization, from creating a mortgage pool to issuing CMO certificates and passing mortgage payments to certificate holders. Then we pinpoint two main elements, namely interest rate models and prepayment models, and show their impact on securitization of a mortgage pool. First we consider interest rate models. We compare briefly different interest rate models including classical short rate models, HJM class models and the String Market Model presented by Santa-Clara and Sornette,

$$d_t f(t,x) = \alpha(t,x)dt + \sigma(t,x)d_t Z(t,x), \qquad (1)$$

We present the descritized version of (1) which does not allow the arbitrage. We also show two calibration approaches: historical and market prices. After that, we mention few prepayment models and pay special attention to optimal recursive refinancing shown by Longstaff which uses regression and dynamical programming techniques. At the end, we combine all elements to define an optimization problem that can be used to increase the efficiency of securitization problems. We define the efficiency in two ways. The first one is to maximize CMO issuer profits. We can define profits as a function of four cash flows: payments made to the crediting bank, payments made by CMO certificate holders, mortgage scheduled payments, and CMO certificates scheduled payments. The second way is to propose a securitization scheme under the assumption that Z-tranche is unattractive to investors. We illustrate that 'ad hoc' securitization may be far less efficient than solving an optimization problem.

A mathematical model for longevity prediction of lacquer-paint coatings in sea water. **Victor Shevchuk** (National Academy of Sciences of Ukraine, Kyiv), Pavlo Shevchuk (Pidstryhach Institute, Ukraine) IC/CT563/010

The prediction of longevity of lacquer-paint protective coatings in aggressive environments is an important problem, which is usually solved on the basis of long-term and expensive testing. However, it is possible to elaborate an adequate mathematical model of coatings aging for analytical calculations of coating lifetime, using geometrical and physicomechanical parameters of the model experimentally determined in laboratory conditions. Since the mechanism of coatings destruction during exploitation in sea water is extremely complicated and includes a great number of consecutive and parallel physico-chemical and structural changes, the development of the mathematical model of such a complicated mechanism needs its formalization. This formalization takes into account the main processes of the mechanism and provides the possibility of its mathematical description.

This paper presents a polyparameter mathematical model, which has been elaborated with the use of the methods of continuum mechanics and non-equilibrium thermodynamics. The model is based on the detailed study of the laws of physico-chemical, electrochemical and other processes in the system sea water-coating-metal base, on the analysis of the failure mechanism of coatings and on certain results of purposeful laboratory measurements.

To simplify the model, the whole process of coating aging in sea water is represented in the form of a number of subsequent stages with the mathematical description of determining physical parameters on each of them up to cohesive or adhesive failure of a coating. For each of these typical stages of the coatings aging process, the appropriate linear or nonlinear boundary value problems of mathematical physics have been formulated, and the procedure of their analytico-numerical solving has been elaborated.

The numerical investigations allow discovering a number of the new regularities of coatings aging. The elaborated mathematical model gives possibility to predict the lifetime of coatings, to quickly analyze the influence of their certain characteristics, operation conditions, and technological factors on the coatings longevity, to optimize the parameters of newly constructed coatings with the aim of increasing their durability and to make appropriate corrections still on the stage of their production.

The application of the FDEM program package with error estimate to industrial problems. **Torsten Adolph** (Forschungszentrum Karlsruhe, Germany), Willi Schönauer (Forschungszentrum Karlsruhe, Germany) IC/CT2245/015

The Finite Difference Element Method (FDEM) program package is a robust and efficient black-box solver that solves arbitrary non-linear systems of elliptic and parabolic partial differential equations under arbitrary non-linear boundary conditions on arbitrary domains in 2-D and 3-D. FDEM is an unprecedented generalization of the finite difference method on unstructured finite element meshes. From the difference of formulas of different order we get an easy access to the discretization error. By the knowledge of this error the mesh may be refined locally to reduce the error to a prescribed relative tolerance. The error estimate is a unique property for such a general black-box. In addition, the FDEM program package is efficiently parallelized on distributed memory parallel computers.

In this paper we demonstrate the usefulness of the FDEM program package by its application to several industrial problems. This gives completely new results as up to now people have solved these problems blindly, unaware of the error of their solution.

The first problem is the numerical simulation of a microreactor where we have two chemical components entering through the main channel and two chemical components entering through a side channel so that there is a reaction of two of the components. We want to examine the flow field and the behaviour of the chemical components.

The second problem is the simulation of the distribution (and possibly of the combustion) of hydrogen in an open domain. We have a small opening at the bottom where the hydrogen enters into the domain filled with air at the beginning.

Thirdly we simulate numerically a high-pressure discharge lamp where we have a constant plasma arc between two electrodes.

Finally we simulate the distribution of the temperature in a DC/AC-converter module with 6 power-MOSFETs heated with uniform power. At the bottom of the module air cooling is applied. In contrast to the first 3 elliptic problems this is a 3-D parabolic problem.

The optimal spatial deployment of radiation portal monitors to improve nuclear detection at overseas ports. **Yifan Liu** (George Mason University, USA) IC/CT2847/158

Radiation portal monitors are starting to be deployed at overseas ports to prevent nuclear weapons from entering the U.S. in a shipping container. Current designs have containers on trucks passing through a portal monitor at approximately 10 mph, before being routed to one of several lanes at the port's front gate for a driver identification check. For a fixed cost of testing, which consists of the costs of radiation portal monitors plus offsite x-ray and possibly manual testing of containers generating a false radiation alarm that cannot be resolved by gamma-ray imaging, we compare the neutron detection limits of the current design and three other designs that do not affect truck congestion at the front gate. Putting a portal monitor at the head of a single queue before trucks are routed to a lane reduces the detection limit by a factor of 2 over the current design. Placing one monitor in each lane, so that testing occurs during processing, improves the detection limit by an additional factor of 4, and using N additional monitors in n sets, each set within the length of a container, requires optimization algorithms to find the best n. Using a mile-long corridor of monitors in tandem could reduce the detection limit by several more orders of magnitude, thereby allowing the detection of highly-enriched uranium.

Integer solution of a set of bilinear equations. **Mariusz Ziolko** (AGH University of Science and Technology, Krakow„ Poland), Michal Nowak (Akademia Górniczo-Hutnicza, Poland) IC/CT1057/015

Transmultiplexer combines several digital signals into a single one. At the transmitter side the M input signals are upsampled, filtered and summed to obtain a composite signal. This signal is sent through a single transmission channel to all recipients. At the receiver side, the composite signal is split into M channels for separation. The signal is filtered and downsampled to obtain the output signals. This system contains linear and time-invariant elements. This facilitates mathematical modelling. The basic idea is the reversibility of all procedures in such a way that all signals could be recovered as precisely as possible. A transmultiplexer achieves perfect reconstruction if output signals are only a delayed version of input signals. To design a transmultiplexer system means to determine such coefficients that fulfil some algebraic equations. This is a difficult task due to the fact that equations are bilinear. One can use numerical procedures to determine filter coefficients by minimizing the residua obtained from equations. Sometimes it is possible to obtain solutions for simple systems. In general however, there are no known methods to solve a set of bilinear equations. What is more, it is difficult even to examine the existence and uniqueness of solutions. Looking for solutions leads to determining the sufficient conditions that can be written in a more simple form. A procedure of this kind will be presented in our paper. Computational algorithm resulting from the theorem and a simple example will be presented as well. Till now, the perfect reconstruction conditions are fulfilled only theoretically because the quantization errors in digital filtering for real numbers are inevitable. Practically, output signals were a little different than input ones. Our method enables to provide all calculations using integer numbers only. Due to the incorporation of integer values, a perfect reconstruction can be realized not only theoretically but also in practice. Thanks to that, transmultiplexer systems equipped with integer filters can be used not only to transmit multimedia signals but also for encrypted data, lossless compressed signals or for computer software data where a change in even one single bit is inadmissible.

Mathematical model for waste minimization of a bleach plant in the paper industry. **Vedpal Singh** (IIT Roorkee, India), Vivek Kumar (IIT Roorkee, India), Deepak Kumar (Indian Institute of Technology Roorkee,Saharanpur) IC/CT4787/159

Mathematical Model for Waste Minimization of a Bleach Plant in Paper Industry

V.P.Singh , Vivek Kumar , Deepak Kumar

Indian Institute of Technology Roorkee,Deptt. of Paper Technology,Saharanpur Campus,Saharanpur -247001, India Email: sighvp2@yahoo.co.on , Fax: +91-132-2714011.

ABSTRACT

Modern pulp bleaching appears to favour multistage bleaching sequences for the production of high brightness market pulp of good quality at low cost. The exact choice of bleaching sequence depends upon the type of pulp to be bleached and the level of the brightness to be achieved. A number of simulation studies have been carried out in order to minimize the amount of effluents from the bleaching plant. Myers et al. (1989, Tappi J. 72, 131-135) used GEMS for the optimum design and for the determination of operating conditions of an oxygen delignification system in order to minimize the delignification costs and to reduce the total organic chlorine emissions from the bleach plant. Brooks et al. (1994, Tappi J. 77, 83-92) used simulation to evaluate the conversion of a conventional oxygen delignified softwood bleach plant to TCF bleaching based on hydrogen peroxide. Parsad et al. (1996, Tappi J. 79, 144-152) made an economic analysis through simulation of a kraft-oxygen mill with modifications of the pre-bleaching and bleaching systems to incorporate TCF and closure issues.

In the present investigation a steady-state mathematical model is developed for a typical four stage CEHH bleaching sequence in Indian Pulp and Paper Industry.Each stage of the sequence is composed of chemical additions and mixing, reaction in a retention tower, and washing. Unit operation models were formulated using mass balances on liquor, fibres, kappa number, chemicals and COD based on the assumption of perfect mixing and quasi steady-state. The COD is used in this paper as an indication of the amount of effluent coming out from four bleaching stages. COD measurement of bleach plant effluent separately is not a routine mill measurement; so COD is calculated in the basis of correlation of COD given by Anjana (2001). In order to validate the model, the simulated results were compared the literature data ; a good agreement between the simulation results with the literature data is achieved. In the case studies, the optimization of the process variables are performed in which the effects of retention tower, operating temperature, residence time, consistency, bleaching liquor flow rate and the wash water flow rates in the washers are studied.

Axisymmetric heat conduction in a multimaterial cylindrical solid. **Whye Teong Ang** (Nanyang Technological University, Singapore) IC/CT419/015

The axisymmetric steady-state heat conduction in a multimaterial cylindrical system is considered. The cylindrical system is made up of four possibly dissimilar materials occupying the regions R_1, R_2, R_3 and R_4 defined by $R_1 = \{(r,\theta,z) : r < r_2,\ 0 < \theta \le 2\pi,\ 0 < z < h_1\}$, $R_2 = \{(r,\theta,z) : r_1 < r < r_2,\ 0 < \theta \le 2\pi,\ h_1 < z < h_2\}$, $R_3 = \{(r,\theta,z) : r < r_1, 0 < \theta \le 2\pi, h_1 < z < h_2\}$ and $R_4 = \{(r,\theta,z) : r < r_2,\ 0 < \theta \le 2\pi,\ h_2 < z < h_3\}$, where r, θ and z are the cylindrical polar coordinates, and r_1, r_2, h_1, h_2 and h_3 are given real constants such that $0 < r_1 < r_2$ and $0 < h_1 < h_2 < h_3$. The interfaces between the materials are perfectly bonded. The curved part of the exterior boundary of the system, that is, the surface $r = r_2$, $0 < z < h_3$, is thermally insulated. Specific types of boundary conditions are imposed on the flat ends of the multimaterial cylinder, e.g. a uniform temperature may be prescribed on each of the flat ends. An analytical formula is derived for the temperature in the multimaterial solid. The coefficients of the truncated series are determined by solving a system of linear algebraic equations. The solution has practical applications in modern engineering, such as in thermal analysis of computer chips and carbon nanotubes. For example, R_1 and R_4 may represent two computer parts separated by a thermal interface material in R_2 whose thermal conductivity is enhanced by a carbon nanotube in R_3.

Numerical simulation of thermal hydraulics in an ADSS model. **BVRathish Kumar Bayya** (IIT Kanpur, India) IC/CT1250/015

Futuristic nuclear reactors like ADSS (Accelerator Driven Subcritical System) have evoked renewed interest in research because it operates in sub-critical conditions and transmutes radioactive nuclear wastes. In an ADSS, a high energy proton beam from the accelerator irradiates a heavy metal target to produce spallation neutrons, which initiate the fission reaction in the sub-critical core. The spallation target module is the most innovative component in the ADSS. The design of the spallation target module requires a fair understanding of the thermal-hydraulics involved, as a large amount of heat is generated in the system during the course of nuclear interactions with the molten liquid metal target. The window, a physical barrier separating the molten metal from the proton beam, is a critical component as it is subject to high heat fluxes, thermal and mechanical stresses. Even though it is relatively easy to take away the total spallation heat by the heavy metal target, what is crucial is that this has to be achieved without the the target temperature exceeding the stipulated temperature in any region of the flow. The presence of any recirculation or stagnation zones of fluid may lead to local hot spots either in the window or in the flowing liquid metal which is detrimental to the performance of the target. This necessitates detailed flow and heat transfer analysis in the spallation region, flow region near the entrance of the annular zone along with the temperature distribution of the window.

indent Numerical simulation has been accomplished using SUPG-FE method of Brooks and Hughes. The solution technique is based on the Eulerian velocity correction approach. This is essentially a variant of the projection scheme of Chorin , which was originally developed in a finite difference context and identical to the Marker And Cell (MAC) method. The computational grid was generated using algebraic method subsequently smoothened and clustered by elliptic partial differential technique using Poisson equation. Simulations have been carried out for various values of Reynolds numbers in laminar and turbulent regime to analyze the flow and temperature field.

indent A conjugate heat transfer analysis is accomplished to incorporate the physical operating situation of an ADSS in a more realistic way. The conduction equation of the beam window is solved in conjunction with the energy equation using the paradigm of domain decomposition parallelization method and the temperature distribution along the beam window is found. Finally, the thermal stresses and mechanical stresses along the radial and circumferential direction on the beam window is determined using temperature and pressure values. The radial stress values are higher compared to the circumferential stress for the case of mechanical stresses but vice versa in the case of thermal stresses.

Electromagnetic and thermal modelling of axisymmetric induction furnaces. **Maria del Carmen Muniz** (Departamento de Matemática Aplicada. Universidade, Spain), Alfredo Bermudez de Castro (Universidade de Santiago de Compostela, Spain), Dolores Gomez Pedreira (Universidade de Santiago de Compostela, Spain), Pilar Salgado (Universidade de Santiago de Compostela, Spain) IC/CT3834/010

A numerical method to describe the thermo-electric behavior of an induction heating furnace is introduced. It is obtained by using an enthalpy formulation concerning the thermal model and an integral representation of the electromagnetic potential in an unbounded domain. A BEM-FEM method is used and an iterative algorithm together with numerical results for an industrial heating system are presented.

A heat engine based on evaporative cooling at reduced pressure. **Noel Barton** (Sunoba Energy Systems, Australia) IC/CT1383/015

A thermodynamic model is presented for a heat engine based on evaporative cooling of hot dry air at reduced pressure. The principle of the new engine is the antithesis of conventional gas or vapour engines, which rely on heating at increased pressure. The new thermodynamic cycle is analysed for a two-stroke reciprocating piston version. The analysis includes the effect of water vapour in the air and further evaporation during re-compression. The engine will be bulky, but well suited to power generation from passive solar pre-heating. As a typical result, air at 35°C and 35% relative humidity pre-heated to 75°C can theoretically produce 3.7 kJ per kg dry air. That corresponds to efficiency of conversion of pre-heating to power of 8.4%. Even without pre-heating, evaporative coolers can produce power.

A fast and robust fictitious-domain method for modeling propellant flow in a three-blade planetary mixer. **Philippe Tanguy** (École Polytechnique de Montréal, Canada), Benjamin Coesnon (École Polytechnique de Montréal, Canada), Vincent Stobiac (École Polytechnique de Montréal, Canada), Francois Bertrand (École Polytechnique de Montréal, Canada), Mourad Heniche (École Polytechnique de Montréal, Canada) IC/CT2528/156

Propellants are energetic materials that play an important role in many industries such as the aeronautic (propulsion of missiles and rockets) and automobile (fast activation of air bags for car safety). In general, the production of propellant requires several unit operations. One of them, which is of interest in this study, is blending through mechanical agitation by means of so-called planetary kneaders. It is known that the investigation of mixer performance through the evaluation of

macroscopic quantities such as mixing time or power draw is a time-consuming and expensive task. 3D CFD simulation may then appear as a useful tool for the design of an efficient mixing process. However, the geometrical complexity of planetary mixers is such that standard CFD methods are just not suitable for the task. To enable simulation of fluid flow in complex geometries with internal moving parts, our research group has been developing over the past ten years finite element based fictitious domain methods that have shown both robust and accurate. The objective of this paper is to introduce our latest fictitious domain method, which is based on a fully coupled solver for the Stokes equations and which yields to a significant reduction of CPU time with respect to the previous uncoupled approach. The method is applied to the simulation of the flow of a viscous polymeric paste, typical of an industrial propellant, in a three-blade planetary mixer. The performance of the method as well as its accuracy will be discussed.

Mathematical modeling of composite patch bonding by means of induction heating. **Theodosios Papathanassiou** (National Technical University of Athens, Greece), George Tsamasphyros (National Technical University of Athens, Greece) IC/CT2413/023

Induction heating is a novel application in the field of patch bonding repair techniques. Heating with the use of induction involves placing an adhesive film, which contains a thin metal grid, between the patch and the damaged area. With the use of coils, Eddy currents are created in the metal grid, providing heat due to the Joule phenomenon. This paper focuses on heat diffusion analysis of this particular methodology. It is of major importance to have the ability of predicting the temperature distribution along composite patches during the bonding procedure. This need emanates from the fact that the structural integrity of a repair depends on several phenomena associated with temperature. Such phenomena are the curing of an epoxy matrix composite patch and the generation of thermal stresses. Simplified, Quasi 2D models of heat transfer along the patch and the plate underneath are derived from the energy conservation principle. The problem reduces to the solution of a system of ordinary differential equations. An analytical solution to the above mentioned system is derived for heating loads of polynomial distributions of random degree. This polynomial form is an adequate simulation considering the fact that any analytical function may be represented as a Taylor series expansion.

IC/CTS4650/15: General incl. microscales.

Organiser: Alexandros Sopasakis (University of North Carolina, USA)
Co-organiser: Endar Nugrahani (Bogor Agricultural University, Indonesia)

Structure and design of a vehicular-traffic model from microscopic stochastic dynamics. **Alexandros Sopasakis** (University of North Carolina, USA) IC/CT1487/015

A novel multi-lane traffic model based on stochastic noise driven dynamics is presented. The model in this work simulates vehicles under the influence of stochastic noice driven interactions. We apply an anisotropic potential and Arrhenius spin-flip and spin-exchange dynamics. This allows for highways with multiple lanes as well as entrances and exits. Vehicles advance based on the energy profile of their surrounding traffic through a novel look-ahead one-directional type interaction potential. The resulting vehicular traffic model is numerically implemented via kinetic Monte Carlo simulations and scrutinized under basic traffic flow situations.

Modeling of vehicular traffic systems. **Endar Nugrahani** (Bogor Agricultural University, Indonesia) IC/CT2995/010

The behavior of traffic systems controlled by traffic lights on a single lane is presented using the optimal velocity model. The effect of different traffic light control strategies on the traffic flow is discussed using three different strategies, i.e. the synchronized, green wave, and random offset strategies. The flow-density diagrams are analyzed using these strategies. It will be shown that the saturation of the flow occurs at the critical density, which depends on the cycle time of the traffic light and the strategy being used.

On the other hand, the behaviour of indvidual cars in a vehicular traffic system will be modelled microscopically using follow-the-leader model. The model deals with traffic flow on a unidirectional roadway in the presence of traffic lights. The responses of individual cars to red, green and yellow lights will be postulated, which gives the rules governing acceleration and deceleration of individual cars. It can be shown that only specific cars in the system are affected by the lights, while the rest behave according to simple follow-the-leader rules. In this scheme, the velocity of individual cars is determined simply by the spacing between it and the vehicle directly ahead. Finally, some simulation results on both models will be presented.

A comparison of adaptive computing and singular perturbation in the impact problem. **Lei Hou** (Shanghai University, PR China), Lin Qiu (Shanghai Jiao Tong University, PR China) IC/CT663/010

The authors applied non-linear numerical method to simulate the viscous-elastic-plastic deformation and its stress distribution . The resolution agrees with the theoretical results from the P-T/T stress PDE (Maxwell)equation. The resulting accelerations (G) have been confirmed by the celebrated European EEVC experimental solutions. Therefore the complex material stress distribution in the large deformation has been obtained. Also the posteriori-estimate solver and singular pertubation method have been used for the sensitive pre-stage deformation before the impact happening. This part of simulation is very interesting for the passive safety in automotive protection devices and airflow triggering control system. It is an important part of the mathematical modelling.

A model of drivers' lane-changing behaviour at an urban signalised intersection. **Shahrum Abdullah** (Universiti Kebangsaan Malaysia), Amiruddin Ismail (Subang Jaya, Malaysia), Ibrahim Ahmad (Univeristi Kebangsaan, Malaysia), Azami Zaharim (Univeristi Kebangsaan, Malaysia), Ibrahim bin Mohamed (University of Malaya, Malaysia) IC/CT4467/010

The aim of this research is to study and develop models for drivers' lane-changing behaviour in an urban area using the logistic regression method. A pilot study was conducted using a videotape recording technique to film an approach road leading to a signalised intersection in an urban road during the morning off-peak period. Inter-related coding methods were designed to describe and verify a driverŠs lane-changing manoeuvre. A questionnaires study to analyse the driverŠs background, experience, attitudes, lane-changing practices and their driving behaviour on the road was carried out in order to develop lane-changing behaviour models using the logistic regression method.

Calculation of effective mechanical properties of textiles by asymptotic approach. **Alexander Nam** (Fraunhofer ITWM, Kaiserslautern, Germany), Julia Orlik (Fraunhofer ITWM, Kaiserslautern, Germany) IC/CT4286/052

We consider plates with 2D periodic rod or fabric structure, used as geo-textiles or textiles. The period of structure as well as the height of the plate are much smaller compared to its depth and width. This makes a direct numerical computation of boundary value or contact elasticity problem too expensive. Two small parameters are introduced for the asymptotic analysis: the first one connected with the period of structure, the other one with the plate height.

The overcoming to the limit with respect to period of structure provides equivalent homogenized plate of the finite height. The next overcoming to the limit with respect to the height reduces the 3D problem to the membrane equations (fourth-order PDE). For the rod structures these successive formal asymptotic expansions and the algorithm for calculation of the effective elastic coefficients for the limitting homogeneous mebrane are given in[1]. In the present work, we have implemented this algorithm. We are going to justify these results by application of two-scale convergence for the first limit, and $\Gamma-$convergence for the second limit, and extend this approach and theory to textiles with sliding fibres; i.e., by adding the contact conditions in the microstructure. From the 3D homogenization (see e.g.[2]) it is known that the effective homogenized body will posess a plastic constitutive law; i.e., a nonlinear membrane equation will be obtained in the second limit.

Transient pressure response in an anisotropic formation. **Ching-Yu Chen** (National University of Kaohsiung, Taiwan) IC/CT4504/154

The transient pressure of a single-phase is analysed here with the fluid being slightly compressible in a porous medium where a non-permeable wellbore is present. The flow is induced by a single probe on the side of an otherwise sealed wellbore which is drilled at an angle to the vertical into the anisotropic rock formation.

The formulation is derived by giving a transient correction due to the presence of the wellbore to the time dependent free space source field solution (the probe). Using the divergence theorem and the zero flux condition on the wellbore surface, a boundary element formulation is derived and solved numerically in the Laplace and Fourier transformed domain before being inverted to give the real time behaviour of the fluid pressure.

IC/CTS4655/15: Microscale, porous media.

Organiser: Oleg Iliev (Fraunhofer ITWM, Kaiserslautern, Germany)

The elasto-plastic behavior of high-performance cast alloys influenced by porosity. **Michael Ries** (TU München, Germany), Christian Krempaszky (TU München, Germany), Brigitte Hadler (TU München, Germany), Ewald Werner (TU München, Germany) IC/CT2350/154

In the design of cast high performance components, the knowledge of the effect of porosity on strength and durability is of high significance.

In this contribution, a model on the mesoscopic scale is proposed to investigate the impact of the topological aspects of the defects on the macroscopic mechanical properties of the material. In a first step only the geometrical properties of the porosity are embedded, micromechanical properties, e.g. anisotropy of the grains and influence of grain boundaries, are neglected. The constitutive behavior of the matrix is assumed to be that of the nonporous material. As a result the homogenized macroscopic behavior of the porous material is obtained. The impact of porosity is quantified by the reduction of Young's modulus, yield limit and tensile strength.

For the experimental validation of the simulations uniaxial tensile tests were conducted in a deformation dilatometer, concerning the elastic and elastoplastic properties of porous and non-porous specimens. The damage-mechanisms are investigated on broken specimens by micrographs and SEM-analysis near the fracture surface to implement them in the model in a later step. The tensile tests are conducted at room temperature and 900°C. The volume-fraction of the porosity of the specimen is obtained previously by computer tomography.

The aim is to identify adequate parameters for the description of the mechanical behavior of the porous area in a sufficient accuracy, that can be obtained by non-destructive analysis in a way as simple as possible.

A tall-block model for miscible displacement in fractured media. **Li-Ming Yeh** (National Chiao Tung University, Taiwan) IC/CT2971/154

The effects of turbulent mechanical mixing of non-stationary, incompressible, two-component, miscible displacement in a fractured medium with tall blocks is studied. In that medium, there is an interconnected system of fracture planes dividing the porous rock into a collection of tall blocks. The fracture planes form paths of high permeability. Most of the fluids reside in tall blocks, where they move very slowly. Let ϵ denote the horizontal to the vertical size ratio of the tall blocks and let permeability, gravity and width ratios of tall blocks to fracture planes be of the orders ϵ^2, ϵ^0 and ϵ^0 respectively. The equations for the two-component, miscible displacement in fractured media converge to a dual-porosity model as ϵ tends to 0. In this talk, we shall explain the dual-porosity model.

Multiscale simulation of filtration processes. **Oleg Iliev** (Fraunhofer ITWM, Kaiserslautern, Germany), Arnulf Latz (Fraunhofer ITWM, Kaiserslautern, Germany), Stefan Rief (Fraunhofer ITWM, Kaiserslautern, Germany), Andreas Wiegmann (Fraunhofer ITWM, Kaiserslautern, Germany) IC/CT4522/154

Modelling and simulation of multiple scale filtration processes is preseneted and discussed. Nano- and micron- size particles often have to be filtrated out of fluids. Filtration medium may have size of milimeters or centimeters, while a complete filter element may be of size of centimeters or meters. Proper models for each of the scales are discussed, with an emphsize on the efficient simulation approaches. The movement and the capturing of the particles is described by a stochastic ODE, while the flow of the fluid is described by Navier-Stookes, or by Navier-Stokes-Brinkman system of PDEs. Efficient solvers for complex geometries which resolve fibers of the filtration media, and for complex geometries describing a filter element, are presented and discussed.

Modelling of displacement washing of pulp fibers. **Vijay Kukreja** (SLIET, Longowal, India), Shelly Arora Shelly Arora (Punjabi University, Patiala, India), SS Dhaliwal (Punjabi University, Patiala, India) IC/CT1004/154

The flow of fluid through the packed bed of porous particles is modelled mathematically with the help of a two parameters, Peclet number and Biot number. The packed bed is divided into three parts namely, zone of flowing liquor, zone of intrapore solute present in the pores of the particles and the zone of solute adsorbed on the particle surface. Langmuir adsorption isotherm is used to describe the relationship between intrapore solute concentration and the concentration of solute adsorbed on the particle surface, whereas the bulk fluid concentration and the intrapore solute concentration are interrelated by linear adsorption isotherm. The domain across the cake thickness is divided into small sub domains called elements and with in each element the technique of orthogonal collocation is applied. The model is validated using the experimental data from a lab scale pilot plant. Indian wood pulp fibers consisting of Eucalyptus and Bamboo were used to run these experiments. The model predicted values are also compared with the experimental values.

IC/CTS4651/15: Inverse problems.

Organiser: John Stockie (Simon Fraser University, Canada)

A level-set technique for an inverse problem for Maxwell's equations in 3D. **Oliver Dorn** (Universidad Carlos III de Madrid, Spain) IC/CT2902/155

Inverse problems for Maxwell's equations in 3D play an important role in a variety of important real-world applications, for example in non-destructive testing, in mine detection, in medical imaging, in the characterization of petroleum reservoirs or in the monitoring of pollutant plumes in the Earth. The majority of inversion codes nowadays still use lower-dimensional simplifications of the full 3D system of Maxwell's equations in order to invert the data. Even though these simplified models work well in some situations of special geometry, in the general case the results they yield are not satisfactory since the problem at hand is intrinsically 3D. We will present a new technique for the identification and characterization of geophysical shapes from low-frequency electromagnetic data which uses the full system of Maxwell's equations and a 3D level set technique for solving the inverse problem. The computational cost is reduced by employing a so-called *adjoint scheme* for calculating repeated corrections for an initial guess in an iterative manner. We show that our technique is able to reconstruct and characterize hidden shapes in 3D (as for example pollutant plumes in the Earth) from relatively few noisy electromagnetic data in a stable and efficient way for realistic geophysical situations.

Level-set reconstruction from two-phase flow data incorporating statistical techniques. **Rossmary Villegas** (Universidad Carlos III de Madrid, Spain), Oliver Dorn (Universidad Carlos III de Madrid, Spain), Miguel Moscoso (Universidad Carlos III de Madrid, Spain), Manuel Kindelan (Universidad Carlos III de Madrid, Spain) IC/CT3016/155

In previous work our group has presented a novel technique for the characterization of reservoirs with more than one lithofacies which is based on a level set representation of different geological regions. In this approach the evolution of the level set function (and therefore of the geological regions) during the reconstruction is based on a gradient flow. In each step, a direct simulation and an adjoint simulation is employed in order to calculate in an efficient way descent directions of a given cost functional. If an adjoint simulator is not available, descent directions need to be calculated in a different way. In the talk we investigate and discuss alternative techniques for designing a level set evolution that does not require the use of an adjoint simulator. In particular, we will employ stochastic techniques for finding approximations or replacements of the gradient directions during the evolution of the level set function such that the final result (and therefore the final geological regions) will honor production data. We compare the performance of these adjoint-free techniques with our previous gradient based techniques. In particular, we will investigate and compare speed and accuracy of the corresponding reconstructions using realistic 2D situations with noisy production data.

An inverse Gaussian-plume approach for estimating pollutant emissions. **John Stockie** (Simon Fraser University, Canada) IC/CT1594/155

Environmental monitoring is an essential aspect of managing many large industrial operations wherein potentially harmful pollutants are potentially released into the environment. Tracking of pollutants in the atmosphere typically involves understanding a number of transport processes including turbulent and/or molecular diffusion, advective transport by the wind, and deposition on the earth's surface. The Gaussian plume model is a steady state model which yields a simple analytical solution to the atmospheric transport equations that depends linearly on the emission rate, Q. The Gaussian plume solution has been used to great advantage in developing industry-standard software packages that track pollutant emissions for known Q; however, relatively little work has been done on the inverse problem, namely estimating Q given measurements of particles deposited on the ground surface.

I will present a study of a large mining operation which involved estimating pollutant emission rates for several sources distributed spatially over an actual industrial site. A linear least squares optimization approach is employed to estimate the sources, and the ill-conditioning of the inverse approach is discussed. A forward solver for integrating the unsteady atmospheric transport equations – based on the high resolution algorithms implemented in CLAWPACK – is also proposed to validate the results.

This project is joint work with Ed Kniel (Teck Cominco Ltd.), Enkeleida Lushi (NYU), and Evgeniy Lebed (UBC).

Variational approach to the inverse identification of cracks from boundary measurements. **Rumena Tsotsova** (Universität Karlsruhe, Germany) IC/CT2638/155

This study presents a variational method for identification of internal cracks in isotropic homogeneous body. The method is based on measurement data collected on the boundary of the solid (displacement and traction fields). The determination of the crack position, topology and shape can be considered as a free-discontinuity problem with the unknown pair $(\mathbf{u}, K)$, where $\mathbf{u}$ represents the displacement vector in the unfractured part of the body and K the crack surface.

To obtain the solution pair $(\mathbf{u}, K)$ a functional, based on the variational formulation provided by Mumford and Shah [1] can be utilized. The variational relaxation with elliptic lower semicontinuous functional of the primal variational formulation proposed by Ambrosio and Tortorelli [2] Γ-converges to the strong discontinuity problem of static fracture mechanics (non-propagating crack) and by finite element method, it can be numerically minimized with respect to $\mathbf{u}$ and the defect parameter ϕ. The defect parameter is a $\mathbb{H}^1$-function on the reference placement of the solid body with values in the interval $[0, 1]$ and can be interpreted as a smooth indicator for the states between: *crack* ($\phi = 0$), and *solid* ($\phi = 1$).

A Mathematical model for a nonlinear soil-column experiment. **Gongsheng Li** (Shandong University of Technology, PR China), De Yao (Shandong University of Technology, PR China), Yongji Tan (Fudan University, PR China), Hongliang Liu (Shadong University of Technology, PR China) IC/CT2815/155

This paper deals with a one-dimensional soil-column experiment and its mathematical models. Due to the nonlinear behaviors of solute transportation in soils and groundwater, the ordinary retardation factor could be a nonlinear function of solute concentration, and the zero production term could be modified to a nonlinear term related with the time and solute concentration, and then a new mathematical model is put forward for nonlinear soil-column experiments. Furthermore, a real soil-column experiment in Zibo, Shandong Province is investigated, and an inverse problem of determining the source coefficients of the model is set forth according to the additional data of breakthrough curves (BTCs). By applying an optimal perturbation algorithm instead of regularization strategies, the source coefficient is determined both in the cases of accurate data and noisy data. The computational results show that the optimal perturbation algorithm is efficient at least in the problem of this paper, and the mathematical model here could be applied to explore some soil-column experiments with nonlinear transport behaviors.

3D complex structures imaging based on acoustic wave equation. **Wensheng Zhang** (Chinese Academy of Sciences) IC/CT801/155

Structures imaging is an important data processing step to detect oil reservoir in oil geophysical exploration. In the point of mathematical view, it solves an initial value problem of acoustic wave equation. In this paper, the hybrid imaging method based on 3D acoustic wave equation is investigated, and some new corresponding computational schemes are proposed. Firstly, the 3D full-way acoustic wave equation is decomposed into a coupled system of one-way wave equations, which describes the propagation of downgoing wave and upcoming wave. In order to obtain images of structures, the known-data which recorded on the surface (initial data) are required to extrapolate along depth or travel-time direction. The extrapolating equations for the downgoing wave and upcoming wave are the uncoupled one-way equations, which is an approximation of the coupled system under the assumption of neglecting multiple reflections. Secondly, the hybrid method and its computational schemes for solving the one-way equations are derived. The hybrid method extrapolates wavefield in the frequency-space domain with the finite-different method and in the frequency-wavenumber domain with the fast Fourier transform (FFT) alternatively, and it possesses the advantages of high imaging accuracy. Two kinds of extrapolating algorithm are considered. One is the two-way splitting scheme, which extrapolates wavefield along two perpendicular directions alternatively. The two-way splitting scheme contributes to solving two tri-diagonal equations successively and has the virtue of high computational efficiency. However, it may cause azimuth numerical errors. The other is the four-way splitting scheme, which extrapolates wavefield along four different directions alternatively. The four-way splitting scheme may reduce the numerical anisotropic errors caused by the two-way splitting scheme. All schemes and the relevant error analysis are given. Thirdly, the numerical calculations both for a pulse response and a complicated benchmark model are completed. Since the 3D wavefield extrapolation is a large scale computational problem, parallel programming based on the Message Passing Interface (MPI) is used to improve computational efficiency. The computational codes are performed on PC cluster and high parallel efficiency is obtained. It is noted that the proposed algorithm can yield accurate images for 3D complex structures.

Compositional space parameterization for multi-component multiphase flow in reservoirs. **Denis Voskov** (Stanford University, USA), Hamdi Tchelepi (Stanford University, USA) IC/CT3049/156

We describe a robust and computationally efficient method for large-scale compositional reservoir simulation involving large numbers of components (e.g. gas injection processes). In the standard compositional simulation approach, an Equation Of State (EOS) is used to describe the phase equilibrium. For each gridblock, given the temperature, pressure and overall compositions, the EOS is used to detect the phase state (e.g., one, two, or three phases), and if multiple phases are present, calculate the phase compositions. These EOS computations can dominate the overall simulation cost. This is especially the case for simulations of gas injection processes involving large numbers of components (five or more) in highly detailed reservoir models.

We propose a different approach based on compositional space parameterization (CSP) in terms of the tie-lines. This approach makes full use of the improved theoretical understanding of compositional gas-injection processes developed by Orr and co-workers over the last two decades. In the CSP simulation method, the basic idea is to represent any composition in the tie-line space using (1) a set of parameters, which determine uniquely the tie-line that intersects this composition, and (2) the overall concentration of one component, which locates the specific location of the mixture composition on the tie-line. The CSP based algorithm has been implemented in a general-purpose research simulator. Using several challenging compositional simulation problems of practical interest, we demonstrate the robustness and superior computational efficiency of the CSP method. Our computational experience indicates that the CSP approach is (at least) an order of magnitude more efficient than standard EOS-based simulations.

Parameterization for mesoscale ocean transport through random-flow models. **Banu Baydil** (Rensselaer Polytechnic Institute, USA), Peter Kramer (Rensselaer Polytechnic Institute, USA), Shafer Smith (New York University, USA) IC/CT4123/156

We describe a mathematical approach based on homogenization theory toward representing the effects of mesoscale coherent structures, waves, and turbulence on large-scale transport in the ocean. We are developing a systematic parameterization strategy by building up deterministic and random subgrid-scale flow models in an increasing hierarchy of complexity, coupling the results from numerical simulations of cell problems with asymptotic analysis with respect to key nondimensional physical parameters such as Peclét and Strouhal numbers.

A two immiscible liquids penetration model for surface-driven capillary flows. **Riccardo Fazio** (Università degli Studi di Messina, Italy), Giovanni Cavaccini (Alenia Aronautica, Italy), Vincenza Pianese (Alenia Aronautica, Italy), Salvatore Iacono (Università degli Studi di Messina, Italy), Alessandra Jannelli (Università degli Studi di Messina, Italy) IC/CT865/156

At the beginning of the nineteen century Young and Laplace, working independently, were the first to report on theoretical studies concerning surface tension and capillarity. Their work, made approximatively at the same time, reported that the static pressure on the liquid side of the liquid-air interface is reduced by the effect of the surface tension. Later, Hagen and Poiseuille, studied the flow of viscous liquids in circular pipes (and capillary tubes in particular), derived the well-known Poiseuille flow profile for a laminar, fully developed, Newtonian fluid. Reynolds tested experimentally the stability of the Poiseuille profile, finding that it held in the case of laminar flow. The dynamics of liquid flow into a capillary, has been modelled by the classical Washburn equation, the Bosanquet model, and, more recently, the SNC model (by Szekely et al.). Applications of surface tension driven capillary flows range from liquid penetration in non-destructive tests to porous membrane and substrates absorption in medicine and personal care. Our main concern is to define a two immiscible liquids penetration model. Moreover, we would be interested to study horizontal closed-end capillaries. In this context, the effect of the entrapped gas on the liquid dynamics was investigated, first, by Deutsch from a theoretical viewpoint, and, more recently, by Pesse et al. from an experimental one. At the end of the presentation several numerical simulations will be reported.

Multigrid fictitious-boundary and grid-deformation methods for flow-induced rotation of wing. **Decheng Wan** (Shanghai Jiao Tong University, PR China) IC/CT2310/156

Flow-induced rotation of wing in incompressible viscous flows are often met in aero- and hydro- dynamics. For example, an airfoil that has a fixed center of mass can be induced to rotate freely around its center of mass due to hydrodynamic forces under the action of an incoming incompressible viscous flow in a channel. It is quite hard to simulate the flow induced rotation of wing in incompressible viscous flows, since different differential equations must be satisfied on each side of the interface between fluid and wing and the solutions are coupled through relationships or jump conditions that must hold at the interface. The movement of both the interface and the wing is unknown in advance and must be determined as part of the solution, it can require a huge amount of time for the generation of a boundary-fitted mesh for each different position of the moving wing. In this paper, numerical simulations of flow-induced rotation of wing by multigrid fictitious boundary and grid deformation methods are presented. The flow is computed by a special ALE formulation with a multigrid finite element solver. The solid wing is allowed to move freely through the computational mesh which is adaptively aligned by a special mesh deformation method such that the accuracy for dealing with the interaction between the fluid and the solid wing is highly improved. The advantage of this approach is that no expensive remeshing has to be performed, and the accuracy for capturing the surfaces of solid wing is highly preserved since the grid points are concentrated near the surfaces of the wing. Here, only the solution of additional linear Poisson problems in every time step is required for generating the deformation grid, which means that the additional work is significantly less than the main fluid-solid part. Several numerical examples of 2D flow around free rotation wing in a channel are provided to show the efficiency of the presented method.

Microcomputer-based simulation of heat conduction between solid of tapered shape and the fluid. **Purnima Shrivastava** (Patna University, India) IC/CT3984/156

Simulating the heat conduction in between a solid conducting body immersed in fluid at a given temperature is a difficult task, particularly when the body is tapered in shape and the simulation is to be carried out on microcomputer. The writer has worked in the past on particular solutions through analytical methods and has encountered the practical difficulties arising out of numerical modelling.

The body in question is cylindrical, symmetrical about z-axis, of length l, tapered in shape and has been heated to a high temperature before being immersed into fluid (water at 50deg. c).The heat conduction equation in polar coordinates is attempted to be solved in two ways- first analytically making use of Bessel's function. A specific solution has been obtained as the boundary conditions are all derivatives of temperature w.r.t. either radius or height.

Secondly, the numerical modelling has been attempted with the help of Finite Difference method. Attempt has been made to solve the equations thus formed through ADI implicite scheme on microcomputer, which seems difficult due to large memory requirements. A change in algorithm is required.

The talk seeks to give an account of work already done on this and would include further possibilities for general solution under the all derivative boundary conditions with analytical methods and for a suitable numerical solution on microcomputer (for a low- cost solution). Also, any possible analogy with flow of fluids shall be discussed.

Positive 2D hybrid linear systems. **Tadeusz Kaczorek** (Politechnika Warszawska, Poland) IC/CT3312/015

Abstract: A new class of positive hybrid linear systems is introduced. The solution of the hybrid system is derived and necessary and sufficient condition for the positvity of the class of hybrid systems are established. The classical Cayley-Hamilton theorem is extended for the hybrid systems. The reachability of the hybrid system is considered and sufficient conditions for the reachability are established. The considerations are illustrated by a numerical example.

IC/PP4288/096: **Modeling and simulation of suction caisson: a study of plastic analysis theory.**

Presenter: Hooman Monajemi (University of Malaya, Malaysia)
Co-author: Hashim Abdul Razak (University of Malaya, Malaysia)

Suction caisson foundation are subjected to different combination of horizontal, vertical and moment loadings depending on the type of structure which they are used for. In addition the optimum ultimate capacity of the suction caisson subjected to the combined loading depends on a variety of parameters such as caissons aspect ratio, soil property and etc. The skirt length to the diameter ratio (L/D) is generally less than 1 for fixed structures like jacket platforms or wind turbines and more than 1 for the suction caissons used as anchors in tension leg platforms (TLP) or floating structures. For large values of L/D they

are sometimes referred to as suction piles. The behavior of the suction caisson subjected to lateral loading is presented in this paper using plastic limit analyses (PLA) method and finite element simulation. This is to observe the effects of aspect ratio (L/D) and soil properties to the failure mechanism and lateral ultimate capacity of the foundation. A combination of horizontal and rotational reaction due to the lateral loading is considered and the ultimate capacity of the foundation for the combined horizontal moment loading is elaborated. This can be done by applying combination of horizontal displacement and rotation to the suction caisson. The general purpose finite element program DIANA is being used for this study. A non-linear analysis was performed on a three dimensional model formed using eight- node isoparametric solid brick elements. The soil was modeled as an elastic perfectly plastic material with Von Mises yield criterion for saturated clay. The plastic limit analyses (PLA) is an upper bound plasticity formulation which is base on calculation of the rate of internal energy dissipation equate to the rate of work due to the external loads. The ultimate load capacity calculated from PLA methods can be use as a benchmark to evaluate the accuracy of FEM solutions.

IC/PP4379/015: Continuous solutions in boundary-layer problem.

Presenter: Aliona Dreglea (Dublin Institute of Technology, Ireland)

Let us consider the following BVP:

$$\begin{cases} x'''(t) + M(x(t),t)x''(t) = 0\,,\ \alpha < t < \beta\,, \\ x(\alpha) = a\,, \quad x'(\alpha) = b\,, \quad x(\beta) = c\,. \end{cases}$$

Some problems from the theory of boundary layer in fluid dynamics [1–2], can be reduced to mentioned problem. Let a function $M(x,t)$ be defined and continuous in the area

$$D = \{x,t|\ |x| \le |a| + |b|\,|\beta| + |c - a - b\beta|\,,\ \alpha \le t \le \beta\}\,,$$

$$m = \min_{x,t\in D} M(x,t)\ \ M = \max\left\{\max_{x,t\in D} M(x,t), 0\right\}$$

In special case $\max M(x,t) = x$, $\alpha = 0$, $\beta = 1$ in the monograph [3, pp.412–413)] existence of a solution has been proven. In this talk we proof the solution existence for this BVP on a finite interval $[\alpha,\beta]$. The function $M(x,t)$ can be any continous function satisfying the condition A.

THEOREM. Let condition A be satisfied. Then the BVP on the $[\alpha,\beta]$ has solution the class $C^{(3)}_{[\alpha,\beta]}$.

IC/PP4517/015: Mathematical and computational modelling for biosensor: a modular approach.

Presenter: Yupeng Liu (Dublin, Ireland)
Co-author: Qi Wang (Dublin, Ireland)

Biosensor are analytic devices which detect biochemical and physiological changes and represent an emerging technology for low-cost , rapid and simple to operate biomedical diagnostic tools.Biosensor has become very significant to our daily life in many areas, home-testing devices for many diseases and disorders, measuring water quality, presenting the harmful microorganisms in food etcs.Biosensor design underpins the development of a range of next generation biomedical diagnostic tools which will directly affect the quality of life worldwide over the next few decades.Using mathematical and computational modeling techniques to characterize the biosensor response as a function of its input parameter in wide range of physical contexts, it can guide experiments, therefore reducing development times and costs.Modular approach of modeling aims to investigate the problem of optimizing biosensor design using an interdisciplinary approach which combines mathematical and computational modeling eighth electrochemistry and biochemistry techniques.Specifically , a collection of simple models will be developed and the used as building blocks towards descrying more complex electrochemical immunoassay systems.The ultimate goal envisaged is the develop a flexible, modular mathematical model, implement in C programming language, which can be used towards a software platform capable of predicting the behavior of a wide range of electrochemical and optical biosensor.

IC/PP476/010: Temperature field of solid body, incorporating cylindrical channel with thermally-thin layer under pulse modes of heat exchange with environment.

Presenter: Nikolay Belyakov (BMSTU, Moscow, Russian Federation)

Using the method of generalized integral transformation and the idea of kernel splitting, an approximate analytical method to solve the appropriate boundary problem for the unlimited solid isotropic body, incorporating a cylindrical channel with thermally-thin surfacing is developed. Special attention is given to the problem of pulse modes of heat exchange. The influence of the thermally-thin layer on temperature field is studied.

IC/PP4695/151: Electromagnetic models of magnetic-flux leakage inspection of steel products.

Presenter: Javier Etcheverry (Tenaris, Argentina)

Magnetic flux leakage (MFL) is one of the most widely used techniques for non-destructive inspection of steel pipes. There are several different equipment designs that specialize to the detection of longitudinal, or transversal, or surface defects. It is also possible, sometimes, to infer the location of the defect from the form of the MFL signal. In order to achieve a better defect detection and improve the classification, it is important to investigate how the detected signal depends on the relevant parameters (location and shape of the defect, excitation field intensity, magnetic properties of the inspected material, etc.).
We will report results for the non-destructive inspection of steel pipes obtained from 2D nonlinear magnetic simulations (using finite element techniques), and present 3-D computations using a coupling between boundary elements (to approximate the problem in the air and non-ferromagnetic materials) and finite elements for the steel. This later approach provides a formulation where only ferromagnetic parts need to be meshed, thus simplifying the set-up of the complex geometries involved. The presented model considers the possibility of including complex nonlinear or hysteretic behavior of the material, thus allowing to evaluate final magnetization states, demagnetization strategies, etc.
This work was done in collaboration with Gustavo Sánchez and Tomás Guozden.

IC/PP2631/156: Assesment of several depth averaged turbulence models for computing turbulent free surface flow in hydraulic structures.

Presenter: Luis Cea (Universidade da Coruña, Spain)
Co-author: M. Elena Vazquez-Cendon (Universidade de Santiago de Compostela, Spain)
Co-author: Luis Pena (Universidade da Coruña, Spain)
Co-author: Jeronimo Puertas (Universidade da Coruña, Spain)

The depth-averaged shallow-water equations have been extensively used in order to model the flow in rivers and coastal regions, flooding and drying problems, and shallow free surface flows in hydraulic structures. The equations assume a vertical length scale much smaller than the horizontal one, which reduces the vertical momentum equation to the hydrostatic pressure distribution. At the same time the velocity field is assumed to be uniform along the vertical direction. Both assumptions are reasonably fulfilled in rivers and coastal regions. However, quite often in hydraulic structures the separation of scales assumption is not fulfilled, at least in some regions of the flow, due to 3D local flow patterns and high turbulence levels. Therefore, it is of most importance to verify with experimental data the quality of the numerical results in different types of hydraulic structures.

In this paper the free surface flow in several hydraulic structures is computed with a depth averaged shallow water model coupled with several turbulence models, which include a mixing length model, a $k-\varepsilon$ model, and an algebraic stress model. In order to take the equations to their limits of application, we have studied flows with a high turbulence intensity, in which the implicit assumptions of the 2D-SWE are partially broken in some regions of the flow. This is specially interesting in order to verify the quality of the numerical results under such *extreme* flow conditions. The flows studied include several designs of small hydros, two designs of vertical slot fishways, and an open channel with a 90^o bend.

In all cases, the numerical velocity and turbulent fields are compared with comprehensive experimental results.

IC/PP41/015: Modeling risk in arbitrage strategies using finite mixtures.

Presenter: Adam Tashman (Stony Brook University, USA)

Arbitrage strategies produce stable, modest returns punctuated by intervals of dramatically poor performance. The weakness stems from an oversight in modeling: seemingly independent bets infrequently become highly correlated to market variables. Thus, the risk in arbitrage strategies is systematically underestimated, and hedging is not properly implemented. A set of arbitrage strategies are examined for evidence of a mixture of distributions. When such structure exists, a finite mixture model is fit to explain the states of high and low correlation. The model uses a logistic regression function for the mixture probability and linear regression functions for the component densities. The covariates considered are stock market return (SP500), volatility (CBOE VIX), swap spread, and credit spread. The dependent variables are index returns for event arbitrage, statistical arbitrage, and convertible arbitrage. The model is applied in a novel hedging strategy, termed mixture hedging. The strategy is back tested over the period 1990-2005, whereby rolling 12-month returns are computed. Event- and convertible arbitrage exhibited evidence of a mixture, while statistical arbitrage did not. The mixture model better explained periods of negative performance than regression analysis. Mixture hedging applied to event arbitrage admitted a maximum drawdown of -0.78 percent, compared to -1.10 percent for the unhedged portfolio. The results indicate that mixture models better capture the regime-switching nature of arbitrage returns, and offer an improved method for hedging risk.

16: Pure Mathematics, Minisymposia

IC/MP521/162: **Topological robotics.**

Organiser: Michael Farber (University of Durham, UK)
Co-organiser: Robert Ghrist (Univ. of Illinois at Urbana-Champaign, USA)
Co-organiser: Daniel Koditschek (University of Pennsylvania, USA)

Topological robotics is a new and rapidly growing area of applied mathematics which uses techniques and perspectives from modern topology in the service of robotics problems.

Topological robotics studies topology of configuration spaces of various mechanisms (e.g. linkages) and applications to control theory which use topology of underlying configuration spaces. The scope of directions of topological robotics includes the theory of robot motion planning algorithms and their applications to collision free control of multiple moving objects. Some important aspects of topological robotics deal with problems of design of specific dynamical systems exhibiting prescribed behavior (modelling autonomous robots moving in various environments). Topological robotics uses methods of modern algebraic topology, Morse theory and the theory of dynamical systems. Combinatorics and the theory of subspace arrangements also play an important role. Recently, methods of geometry on spaces of nonpositive curvature were successfully employed. The talks of the mini-symposium represent several central directions of topological robotics.

Algebraic topology for networks. **Robert Ghrist** (Univ. of Illinois at Urbana-Champaign, USA) IC/MT3528/0

This talk will explain new applications of algebraic topology to problems in networked systems. A typical network of sensors or robots has the goal of monitoring a given environment. With the use of numerous cheap 'local' devices comes the problem of integrating local environmental data into a global picture via (typically wireless) communication links. This integration problem is remarkably amenable to the tools of algebraic topology, especially homology theory and Euler characteristic. The talk will give all the requisite background and provide concrete applications of computational topology to problems involving coverage, hole detection and repair, pursuit and evasion, and target enumeration.

The cohomology ring of chain and polygon spaces. **Jean-Claude Hausmann** (Université de Genève, Switzerland), Michael Farber (University of Durham, UK), Dirk Schütz (University of Durham, UK) IC/MT2463/0

We prove that chain-spaces in R^d (and polygon spaces for $d = 2, 3$) are determined by their cohomology rings.

Betti numbers of random manifolds. **Michael Farber** (University of Durham, UK), Thomas Kappeler (Universität Zürich, Switzerland) IC/MT2117/0

In various fields of applications, such as topological robotics, configuration spaces of mechanical systems depend on a large number of parameters, which typically are only partially known and often can be considered as random variables. Since these parameters determine the topology of the configuration space, the latter can be viewed in such a case as a random manifold. We study mathematical expectations of Betti numbers of random manifolds in the special case of planar linkages, viewing the lengths of the bars of the linkage as random variables. Our main result gives an explicit asymptotic formulae for the mathematical expectations of the Betti numbers for two distinct probability measures describing the statistics of the length vectors when the number of links tends to infinity.

The construction of vector fields for programming work. **Daniel Koditschek** (University of Pennsylvania, USA) IC/MT3712/0

The problem of robot motion planning has stimulated a three decade old literature addressing the construction of paths joining pairs of points in a robotic Şfreespaceť (the topological space arising from the safe placements of a robot in its intended physical environment). The problem has been shown to be hard from a number of different viewpoints. Most recently, Farber and colleagues have used classical techniques of topology to show that continuous motion planners cannot exist over most freespaces of practical interest, and have developed estimates for the minimal number of components into which such planners must be decomposed in a growing number of relevant cases.
When a robot is required to perform some work within its environment then it is most natural to seek a planner taking the form of a vector field (or, more generally, a family of hybrid dynamical systems) whose attractors satisfy the predicates characterizing desired goal conditions and whose repellors include any states with unsafe or otherwise forbidden properties. This problem has received far less attention in the literature. There are relatively few constructive methods available and the fundamental limitations are not yet well characterized.
This talk will review the general problem of programming work, provide some practical examples of successful constructions, and speculate on the nature of the fundamental limitations.

16: Pure Mathematics, Contributed Talks

IC/CTS4899/16: **Pure mathematics.**

Singular initial-value problems for functional-differential equations: solvability, number of solutions, asymptotics. **Oleksandr Zernov** (South Ukrainian State Pedagogical University) IC/CT792/163

We will speak about linear, perturbed linear and nonlinear equations. Also we will speak about hybrid systems which contain both regular and singular systems, or which contain subsystems with distinct types of singularity. We find solutions with required asymptotic properties by means of quilitative methods. Most of the results are new and have not been published before.

On conformal mappings of spherical domains with given scale functions. **Ludmila Bourchtein** (Universidade Federal de Pelotas, Brazil), Andrei Bourchtein (Universidade Federal de Pelotas, Brazil) IC/CT1366/163

One of the most widespread approaches to planar representation of the Earth surface, required in different problems of geophysics, geodesy and cartography, is conformal mapping. To measure the degree of distortion caused by a projection of the spherical domain Ω onto a plane, the distortion coefficient $\delta(\Omega) = \sup_\Omega m / \inf_\Omega m$ can be used, where m is the scale function defined as the ratio between the elementary arc lengths along a planar curve and respective spherical curve. The distortion coefficient represents the quantitative evaluation for both cartography distortion and computational grid efficiency because the number of time steps of an explicit or semi-implicit scheme implemented on a δ-distortion grid increases δ times as compared with implementation on "ideal" physically uniform grid with $\delta = 1$.

One of the open problems in flattening the sphere surface is the construction of the conformal mappings with prescribed properties of scaling, in particular, the problem of finding the projections with the minimum possible distortion. In this study, the problem of finding the conformal mapping from a sphere onto a plane with a given scale function independent of longitude is solved for an arbitrary spherical domain. The obtained results are compared with the well-known projections used in cartography and geophysical fluid dynamics. The problem of minimization of the distortion under conformal mappings is solved for domains in the form of the spherical disk. The efficiency of the computational grids based on the minimum distortion projections is evaluated in comparison with conventional grids.

On some generalizations of the classical Riemann problem and its corollaries. **Irina Dmitrieva** (South Ukrainian State Pedagogical University) IC/CT525/163

We are looking for a function $F(z)$ that is analytic everywhere on complex plane or on any other algebraic surface of nonzero genus excepting not the obligatory finite set of the ramification points. The function's values undergo the corresponding permutations when passing round these points, and $F(z)$ is assumed to have a finite order at infinity.

Here the following moments have to be underlined: in the classical statement of Riemann problem the set of ramification points was the finite one, all the appropriate permutations were of one and the same dimensions and the unknown function was sought on complex plane [Riemann, B., Gessamelte Mathematische Werke, 2. Aufl., Teubner, Leipzig, 1892]. In our case the proposed problem is investigated not only on complex plane, but on any algebraic surface of finite genus, though this fact is not a principal one here, because some results in this direction were obtained earlier [Dmitrieva, I. Yu., Factorization of Noncom. Permut. Matrices on an Algebr. Surf. of Nonzero Genus, St. Petersburg Math. J. 4(1993), No. 2, 309 - 318].

The most important facts, that considerably differ from the classical statement, in our case consist of : 1) the set of ramification points is not obligatory a finite one:; 2) to every ramification point corresponds the permutation of its own dimension, i.e. the permutations' orders are not equal to each other. Therefore, we obtain here the generalization of the notion of Riemann surface not only in the classical sense, but also as a new aspect for the algebraic surface covering.

At the same time we have come to the homogeneous vector boundary Riemann - Hilbert problem in the new terms and with the special construction of the permutative matrix coefficient.

Relevant applications concern mostly the field theory.

Non-local Dirichlet forms generated by pseudo-differential operators on compact Abelian groups. **Emil Popescu** (Technical University of Civil Engineering, Romania) IC/CT2977/163

Let G_i, $1 \leq i \leq n$, be compact abelian groups and let Γ_i, $1 \leq i \leq n$, be countable dual groups. We consider $G = G_1 \oplus G_2 \oplus ... \oplus G_n$ and $\Gamma = \Gamma_1 \oplus \Gamma_2 \oplus ... \oplus \Gamma_n$. For $1 \leq j \leq n$, let a_j be a negative definite function on Γ_j and $a(\gamma) = \sum_{j=1}^n a_j\left(\gamma_j\right)$. For $\varphi \in S(G)$, the set of all generalized trigonometrical polynomials on G, we define $L\varphi(x) = \sum_{j=1}^n b_j\left(x_j'\right) A_j \varphi(x)$, where $\widehat{A_j\varphi}(\gamma) = a_j\left(\gamma_j\right)\hat{\varphi}(\gamma)$, $1 \leq j \leq n$. Then $B(\varphi,\psi) = \sum_{j=1}^n \int_G b_j\left(x_j'\right) A_j^{1/2}\varphi(x)\overline{A_j^{1/2}\psi(x)}\mathrm{d}x$ is a Dirichlet form with the domain $H_a^{1/2}(G) = \left\{u \in L^2(G) \mid \sum_{\gamma\in\Gamma}(1+a(\gamma)) \mid \hat{u}(\gamma)\mid^2 < \infty\right\}$ on $L^2(G)$. The properties of fractional powers of continuous negative definite functions and their corresponding Dirichlet forms are also investigated.

Induced topology on fuzzy singletons. **Velu Lakshmana Gomathi Nayagam** (NIT Tiruchirappalli, India), Geetha Sivaraman (Thiagarajar College, Trichy, India) IC/CT4532/162

The notion of fuzzy sets was introduced by L.A. Zadeh (1965). The notion of fuzzy topological spaces was introduced and studied by C.L.Chang (1968). The notion of fuzzy singletons is introduced by Pao and Liu (1980). In this paper the notion of induced topology on the collection of fuzzy singletons with respect to a fuzzy topological space is introduced and studied. The relation of the existing notions of Fuzzy separation axioms, Fuzzy compactness and Fuzzy connectedness with the notions of Separation axioms, Compactness and Connectedness in this topology have been studied.

What is really the differential? the fundamental concept of calculus. **José Manuel Olivencia Quiñones** (Universidad Nacional de Trujillo, Peru), Orlando Martín Hernández Bracamonte (Universidad Nacional de Trujillo, Peru) IC/CT874/017

The use of the differential concept is necessary, frequent but poorly understood. Our preoccupation is not centered in the purely mathematical sense, but also in its applications. The differential concept is usually relegated in the teaching of the mathematics, by the contrary, is very useful in the reasoning and mathematical formalization of applied situations. Since the birth of the differential calculus to current time, the differential concept was debated between its identification with the infinitely small amounts and their reduction to a subordinated expression without own meaning (the differential of Newton and Leibniz and later the differential of Cauchy).

In this work, a clarification is carried out, that is able to reconcile, on the one hand, the close relation with the applied situations of the differential expressions of Newton, Leibniz and Cauchy, and, on the other hand, the rigour and the precision of its meaning, achieving a suitable and useful understanding of the differential concept. For it, we simply use the differential definition like a linear transformation and conceiving it like so, working in the space of the linear transformations, it is perceived with great clarity that the differential, instead of being an infinitesimal increase, it is the best linear approximation of the variation of a function at a point, furthermore, it is the unique linear estimation that, via integration, produces the exact relation between the variation of the independent variable and the variation of the dependent variable. In our experience, this conception is producing encouraging results. It is even established, of a very natural way, a differential algebra, that allows performing operations with the differentials, with great facility, maintaining the intuitive sense and without losing the obtained clarification.

IC/PP1253/010: On applications of q-fractional calculus.

Presenter: Sunil Purohit (Udaipur, India)
Co-author: Rajendra Yadav (DEPARTMENT OF MATHEMATICS & STATISTICS, J. N. VYAS, India)

The object of this paper is to illustrate how the q-fractional calculus approach can be employed to derive a transformation expressing a generalized basic hypergeometric function in terms of a finite sum of lower order functions. A further generalization of the main result is also deduced. Known results due to Karlsson, P.W. [J. Math. Phys., 12 (1971), 270-271] and Raina, R.K. [Rend. Sem. Mat. Univ. Padova, 83 (1990), 7-12] follows as the limiting cases of the main results.

IC/PP3066/163: Quasi-conformal extension of biholomorphic mappings in several complex variables.

Presenter: Paula Curt (Universitatea Babeş-Bolyai, Romania)
Co-author: Gabriela Kohr (Universitatea Babeş-Bolyai, Romania)

In this work we present sufficient conditions for the first element of a Loewner chain to be extended to a quasiconformal homeomorphism of $\overline{\mathbb{R}}^{2n}$ onto itself. Interesting applications will be also considered.

IC/PP2932/163: Modern and recent contributions in the theory of Loewner chains of several complex variables.

Presenter: Gabriela Kohr (Universitatea Babeş-Bolyai, Romania)

In this work we present modern contributions in the theory of Loewner chains and the Loewner differential equation in several complex variables. Interesting applications will be presented.

IC/PP4162/163: A study of unified finite integrals and expansion formulae for the $\bar{H}$ function, with application.

Presenter: Anil Ramawat (JODHPUR, India)

In this paper we establish one single integral and two multiple integrals involving product of extended Jacobi polynomials, general class of polynomials and the $\bar{H}$ function. These integrals are unified in nature and act as a key formulae from which we can derive as its particular cases, integrals involving a large number of simpler special functions and polynomials. For the sake of illustration, we gave here only one particular case of our first integral which is also new and of interest by itself. An expression formula for the $\bar{H}$ function, in a series involving products of the $\bar{H}$ function and generalized LegendreŠs associated functions is also established. The generalized LegendreŠs associated functions reduce to associated Legendre function on setting $m = n$. Also, on specializing the parameter of the $\bar{H}$ function in the expansions, we may get many interesting expansions. At the end, we give an application of our first integral by inter-connecting them with the Riemann–Liouville type of fractional integral operator.

17: Education Culture and History, Minisymposia

IC/MP179/171: E-learning and remote access tools in applied mathematics.

Organiser: Matti Heilio (Lappeenrannan Teknillinen Yliopisto, Finland)

The cutting edge knowledge in mathematical technology in Europe is found dispersed at small nodes. Virtual environments can be used to bring solutions to training, education and research, to facilitate distributed work processes, provide remote access to knowledge repositories etc. We are focusing on the challenge of using web-based solutions in education of modelling and applied mathematics. We envisage a possibility of a European digital environment, a menu of courses and remote access software tools, built on the concepts of current e-learning technologies.

Topics on the talks include Distant learning in mathematical modelling, Web-tool on differential equations, Remote courses for applied mathematics in the Third World universities, Learning objects and blended learning in web-supported education.

Distant learning in mathematical modelling in Finland. **Seppo Pohjolainen** (Tampereen Teknillinen Yliopisto, Finland) IC/MT3743/171

Department of Mathematics at Tampere University of Technology is coordinating a national network project on mathematical modelling. Ten universities and research institutes are participating in the network project and the teachers of these universities are responsible for certain parts of the courses produced. Students from different universities can study mathematical modelling both individually and collaboratively.

In the project Web-based learning and teaching methods have been developed, content production in mathematical modelling has been supported and administrative measures needed to support web-based learning and teaching have been put into practice.

In the presentation experiences obtained from course planning, courseware production, pedagogy, didactics, technology and student feedback will be presented and analysed in detail.

Learning objects and blended learning in web-supported education. **Helle Rootzen** (Danmarks Tekniske Universitet, Denmark) IC/MT3850/171

Students nowadays differ much more than before; some are very good and some have substantial difficulties even with very basic concepts. *Learning Objects* may be used to ensure that each student gets course material which is at the right level. Further, students have very different learning styles; some learn best by first getting exposed to theory and afterwards seeing examples, while others prefer the opposite order of presentation. Similarly some prefer visual and graphical teaching, some like to see theory written down in formulas, while others get the most out of listening to oral presentations. Learning Objects make it possible for each student to use what suits her best.

Faced with a new generation of students who are used to exploiting the possibilities of the computer, we need a new type of education that will reflect a rethinking of content, form and duration. In the future, education will be in the form of *voucher systems*. You get a set of vouchers and use them to attend the specific chunk of a study programme you need whenever and wherever it suits you. If the providers are to meet these requirements, the task of developing new courses and tailoring these to new students must be manageable. We therefore propose a new type of courses. These are structured around Learning Objects, short complete education sessions, which may be combined in various ways according to the student's interests and levels. We use blended learning where we combine Learning Objects with face-to-face sessions. The ideas are tried out in research-based continuing education in applied statistics.

An important part of our efforts is to create sufficient computer support for cost-effective course development. This is done in three ways: development of a dedicated repository system using metadata, for easy storage and retrieval of Learning Objects; creation of a tool which combines them into courses; and construction of a tool for making Learning Objects.

Design of the web-tool on differential equations. **Peep Miidla** (University of Tartu, Estonia) IC/MT3913/171

In the presentation the principles of designing of the web-tool on differential equations are considered. The main parts of the tool are: lecture notes, exercises, examples, interactive illustrative and modelling facilities, consultation network, blackboard, evaluation system and some others. These parts will be discussed and not all of them have the same weight from the teaching point of view. In some ways the open courseware system could be used, but several things are new in teaching experience. The classical course of ordinary differential equations must be supported by e-learning means and the best didactic possibility seems to be the blended learning.

The talk is based on the experience of Estonia.

Remote courses for applied mathematics at universities in sub-Saharan Africa. **Verdiana Masanja** (University of Dar es Salaam, Tanzania) IC/MT3952/171

The 1990s saw great pressure to expand student enrollment and improve education delivery with dwindling resources at most Sub-Saharan African (SSA) Higher Education Institutions (HEIs). The HEIs saw the solutions to this dilemma in the utilization of Information and Communication Technology (ICT). Many initiatives have been undertaken at many SSA HEIs to foster education and training systems through the effective and relevant use of ICTs and the Internet for learning (eLearning). Projects have been funded to explore eLearning issues such as new learning environments, virtual models of education and training, teachers' training to use ICT in education and the development of eContent. This presentation explores the extent to which such initiatives in four universities in SSA have contributed to the integration of ICT enhanced tools and services in the education and training of remote courses in Applied Mathematics and discusses the potential areas of collaboration.

IC/MP208/171: Virtual environments in applied mathematics.

Organiser: Matti Heilio (Lappeenrannan Teknillinen Yliopisto, Finland)
Co-organiser: Pietro Pantano (Università della Calabria, Italy)

Virtual technologies and digital educational environments are a viable media to support innovative processes. They can be used to bring solutions to training and educational needs, to facilitate distributed and concurrent work processes, provide remote access to software libraries and knowledge repositories. We are witnessing an evolution of educational materials from traditional textbook to interactive cross-media environments. Flexible updates, dynamic edition, easy accesss and

portability. Additional benefits come from hypermedia features. Graphical arts, animation, interactivity and visual effects of user interface are important possibilities opened by the virtual technology and web-distribution.

Topics of the talks include Remote access laboratories in applied mathematics, Art, mathematics and cultural industry, Mathematics and visualization: multi-dimensional digital shapes for e-learning, Cooperative work in a e-learning environment.

Remote access laboratories in applied mathematics. **Matti Heilio** (Lappeenrannan Teknillinen Yliopisto, Finland) IC/MT1357/171

The cutting edge knowledge in the art of mathematical technology in Europe can be located in dispersed nodes, research groups on applied mathematics, mathematical physics, scientific computing. The work of these groups often lead to development of software that represent state-of-the-art scientific knowledge in the field. These environments are often experimental, under revisions, near the laboratory floor of on-going research. This stage sometimes precedes the later development to actual products and commercialization.

Web-technologies are a viable media for innovative processes and knowledge transfer. A possibility to empower the use of mathematics is sharing of software via remote access to software libraries. In this talk I draw attention to the possibility of creating added value for the knowledge repository of applied mathematics and computational methods via remote access software sharing. To illustrate I present examples and refer to the obvious potential of this approach in the modern era of grid computing. Interactive installations created at GMD Institute for Media Communication provide high level visual support for educational purposes. Applications include illustration of string theory, virtual planetarium and topological zoo.Nondifferentiable Interactive Multiobjective BUndle-based optimization System NIMBUS has been developed at the University of Jyväskylä. The WWW interface enables remote handling of optimization problems and experimenting with up-to-date methods.Web System for Solving Diophantine Systems developed at the Petrozavodsk State University is available for distant users. Web-based system for graduate studies - Optimization, Games and Markets developed at the University of Kaunas, offers versatile collection of interactive exercises. By international collaboration the mathematics community could create a powerful service grid, a library of contemporary and proto-level scientific software in modeling, numerical methods and scientific computing.

Art, mathematics and cultural industry: new trends in the digital era. **Mauro Francaviglia** (Università degli Studi di Torino, Italy), Marcella Lorenzi (Università della Calabria, Italy), Pietro Pantano (Università della Calabria, Italy) IC/MT1377/171

Communicating fundamental achievements of Mathematics is by no means simple, so that presenting it in an innovative way is a fascinating challenge dictated by new trends of our Society. Maths and Art have developed in parallel; in our days Maths plays a renewed role in Art, out of which it gains one reason of development. Maths contributes to conceiving and shaping the World, while Art develops the means to harmonise, describe, represent aesthetically our sensations and perception. Programs aimed at developing interactions between Maths and Art belong to the broad field called Mathematics in Cultural Industry. A new way of teaching and communicating Maths should be envisaged, which requires a deeper use of the intertwining between Maths and Art. Where Art is the central theme out of which the existence of mathematical structures is recognized, first as an hidden part and later revealed more explicitly; to extract and understand structures, symmetries and broken symmetries out of their appearance within Art. To obtain new perspectives on Maths use should be done of the modern tools that new technologies provide us: Digital Technologies, Multimedia and Web Technology, in particular. The innovative full teaching project we are currently developing is mainly associated with a Web Portal MArs aimed at allowing a softer way of understanding Maths, at progressive levels of abstraction, where Art comes first and touches the emotions, stimulating the need to penetrate more intimately into the structures which underly Art. Mars will therefore present Art as a way to approach Maths, to enjoy the beautifulness of the structures existing in our vision and representation of the World and eventually to reconstruct the structures and theoretical tools that are necessary to understand and elaborate their true essence. The Portal will host less conventional spaces dedicated to: the development and/or presentation of multimedia; simulations and generative approaches to Mathematical Art; digital technologies to produce Art through Mathematics or to understand Mathematics through Art; new frontiers in Maths stimulated by Digital Art and Artificial Life, Virtual and Augmented Reality; the use of virtual frameworks and agents to make presentations of Maths (and Science in general) more attractive and artistically valid.

Multidimensional digital shapes for e-Learning. **Tor Dokken** (SINTEF, Norway), Ewald Quak (Tallinn University of Technology, Estonia) IC/MT1437/171

The use of digital shapes, either in 3D (through static models) or 4D (through the animation of 3D objects), is especially important for eLearning applications, since such shapes offer a lot of possibilities well beyond reproducing the content of a “flat" book: a molecule can be inspected from different viewpoints; medical students can make their first steps in the training for surgical procedures; 3D characters of computer games can be used for educational purposes as well.

In this talk a number of examples from European and other projects, such as the IST Network of Excellence AIM@SHAPE, will be presented to illustrate how shapes can be viewed as prime contributing factors for eLearning applications.

Cooperative work in an e-Learning environment: the COMSON case. **Valerio Talarico** (Bergische Universität Wuppertal, Germany), Pietro Pantano (Università della Calabria, Italy), Eleonora Bilotta (Università della Calabria, Italy) IC/MT2449/171

COupled Multiscale Simulation and Optimization in Nanoelectronics project is a Marie Curie RTN supported by the European Commission within the 6th Framework Research Programme of the EU. The COMSON project is run by a Consortium whose multiple aims are: to build an experimental software Demonstrator Platform for coupled simulation of devices, interconnects, circuits, EM fields and thermal effects (one single framework for simulation tool, optimisation in compound design space); to provide an e-learning platform to be used as an inter and extra consortium TOK (transfer of knowledge) infrastructure; to provide a collaborative virtual work environment (CWE) to be used both for industrial activities and training.

COMSON merges the know-how of the three major European semiconductor industries with the combined expertise of specialized university groups for developing adequate mathematical models and numerical schemes and realizing them in a CWE leveraging the demonstrator platform. On the one hand, one of the main activities is to test mathematical methods and approaches, so as to assess whether they are capable of addressing the industryŠs problems using the same CWE; on the other hand, the focus is in adequately educating young researchers by obtaining immediate hands-on experience for state-of-the-

art problems through the e-learning and CWE platform.

The COMSON CWE has been designed as a virtual working place (VWP) where each inter-actor can access different tools and facilities, based upon his/her level of expertise and role. The VWP aim is to allow easy sharing of knowledge between interactors by providing an integrated environment that permits natural communication between participants as well as intuitive exploration, discovery and use of tools based on manipulatory interfaces. The core VWP macrocomponents are:

- A 3D representation of a virtual world based on the museum metaphor used to gain access to the various sub systems.
- A 3D lab allowing users to design, share, experiment, manipulate models and systems.
- A fully featured communication facility allowing voice, video and text instant messaging everywhere in the VWP.
- Collaboration tools for knowledge sharing (e-learning), cooperative design and experiment.
- An intelligent multi agent management system to support exploration.

The VWP has been interfaced with a standardized Learning Management Content System (LMCS) and DP remote simulator. The e-learning platform uses different technologies for the preparation of high-quality e-Learning courses sing multimodal interfaces, embodied into virtual 3D agents, which produce attractive interaction with the user in order to improve and scaffold learning. According to the educational and industrial needs, these environments are designed in order to integrate different systems which improve the student skills in this specific field. This environment is an effective approach for obtaining skills in microelectronics by using different learning situations (ranging from video lessons to hands-on experiences in the DP) in which professional training can be activated also for non-specialists.

IC/MP648/015: Transferring mathematical skills and knowledge today and tomorrow: a tribute to Olga Taussky-Todd.

Organiser: Frank Uhlig (Auburn University, USA)

This mini-symposium is interdisciplinary in nature and reaches beyond applied and industrial mathematics. It deals with our innate and cultured math abilities, the role of gender, nature and nurture in learning and teaching mathematics. It is inspired by and in honor of Olga Taussky-Todd. We start with a personal assessment of Olga's influence on mathematics and mathematicians and her role as a torchbearer and teacher for math and science, followed by recent findings in math education and human neuroscience.

In this vein we first develop teaching principles that help students become autonomous math thinkers. This is based on work by G. Harel. Then we look into specific difficulties in teaching and learning linear algebra, using research by A. Sierpinska, J.-L. Dorier and others. These sets of findings both ultimately lead to and ask for curriculum changes in K–12 math teaching.

The second talk gives an exposition of recent research from cognitive psychology and neuroscience of innate math abilities in infants, as well as of the number line perception that we acquire through culture. The latter is related to space conception and specific areas and known activities of the brain. These findings can aid us to teach mathematics more appropriately. The third talk returns to the narrower subject matter of this Congress and tries to draw conclusions for applied mathematics education and applied mathematicians on what to teach students of numerical analysis and how.

Finally there will be a panel discussion of questions and comments from the floor with the presenters. The aim of this minisymposium is to open a dialogue between the applied and industrial math community and concerned math educators, cognitive psychologists, neuroscientists, and College math faculty about the challenges in teaching mathematics and ultimately to help preserve and improve the mathematical base in our culture and society.

Olga Taussky, a torchbearer for mathematics and teacher of mathematicians, and current math-education insights into general math and linear algebra teaching and learning. **Frank Uhlig** (Auburn University, USA) IC/MT4080/174

Olga Taussky-Todd's mathematical and personal life (1906–1995), her achievements and obstacles, her scientific reasoning and teaching all have served as inspiration to many mathematicians.

We describe her role in the mathematics world of the previous century as a torchbearer for mathematics and mathematicians, bearing the *torch of scientific truth* that burns inside of mathematics and its applications. Besides her many deep math contributions—too many to elaborate—she excelled at distilling and presenting mathematical concepts and ideas in her work and gave many visionary math talks. By sharing her mathematical visions freely she has inspired many of us. Her graceful example shall act as a springboard to the lectures of this minisymposium, given in her honor.

Besides discovering and solving mathematics and applications problems, a mathematician's most important task is that of a teacher of others.

What is Mathematics? How do we teach and learn math? Based on work by Guershon Harel: Math teaching encompasses subject matter and conceptual tools, as well as correct ways of thinking mathematically and proper ways of understanding. Desirable ways of thinking must be nurtured in children of all ages. This should cumulatively lead College entering students to understand *algebraic equivalence* in mathematics. Entering students must have repeatedly experienced working with one concept or math problem in several equivalent mathematical forms or in several mathematical languages. The ultimate aim for all students should be to become autonomous and spontaneous thinkers in mathematical situations, from K–12 and beyond, through postgraduate studies, depending on the age level, of course.

Next we describe some recent results of A. Sierpinska, J.-L. Dorier, and others on teaching and learning Linear Algebra, one of Olga Taussky's beloved subjects. Linear Algebra uses three separate languages as tools for understanding: a geometric one, an algebraic one, and an abstract, conceptual one. All interchangeably, with associated difficulties for students and teachers. Most of our students have only experienced concrete, practical thinking and have no practise with abstract, theoretical, or conceptual thinking. However, the abstract language of Linear Algebra is essential to form correct concept images and thereby gain correct ways of understanding and thinking. To achieve this, teachers of a Linear Algebra course need to allow and encourage constant shifts in language and viewpoint of the subject matter so that students become conscious and flexible in order to achieve autonomous thoughts in math.

Is abstract thinking necessary for Linear Algebra? This leads to deeper questions:Is abstract, theoretical thinking needed in math and applied math? Can we do without scientific knowledge and exploration in Academia, or is practical knowledge alone sufficient?

To prepare students for scientific exploration in College requires changes in our K–12 curricula so that theoretical thinking is practised from early age on, and repeatedly, and becomes natural throughout College and beyond.

Can cognitive neuroscience influence math education?. **Edward Hubbard** (INSERM, France) IC/MT4102/174

Over the past twenty years a variety of experiments have converged to demonstrate that adult human numerical and mathematical abilities are based on evolutionarily conserved and developmentally precocious mechanisms. This talk briefly reviews some research results that show striking numerical competencies in both non-human primates and in human infants.

Building on these results, I will discuss current cognitive neuroscience research on the notion of a "mental number line." For example, it is well established that subjects compare two numbers more quickly when the distance between them is large (such as 55 and 94) than when the distance is small (e.g., 55 and 47). Neuroimaging studies have shown that the human ability to compare numbers depends on a part of the brain known as the intraparietal sulcus. Structural imaging studies have found anatomical differences in this region of the brain in children with severe developmental difficulties in math.

As regards the spatial representation of numbers, which in Western culture (writing from left to right) is a mental mapping of small numbers to the left side and of large numbers to the right side, neuroimaging studies show that these abilities depend on regions of the brain involved in our spatial abilities.

Finally, I will propose some specific examples that show how these findings could aid us when teaching mathematics.

How and why should we teach numerical analysis?. **Anne Greenbaum** (University of Washington, USA) IC/MT4209/174

The field of numerical analysis can include: the design, analysis, and computer implementation of algorithms; the use of these algorithms in applications from science and engineering to finance to the internet to video games and computer graphics.
Which of these areas should be emphasized in an introductory numerical analysis course? Applications can be *glitzy*, but if they are introduced without the requisite understanding of the algorithms being used, they run the risk of providing entertainment without much actual learning. On the other hand, convergence proofs can be boring, especially if one has just been introduced to an algorithm and one wants to get a feel for how it works before studying it in depth. Finding the right mix of these ingredients is a challenge for current teachers of numerical analysis, and for anyone trying to convey the importance and mathematical beauty of this field.

In this talk, we discuss some ways of balancing the different aspects and how well or poorly they seem to be working. Of course, measuring how well something works presupposes that one knows what one wants to accomplish. What should the goals of an introductory numerical analysis course be and how do we go about accomplishing those goals? The answers may depend on one's perspective, be it academic or industrial, engineer or biologist or movie maker.

Still there should be some general principles that all can agree on. We discuss possible goals and student expectations as well.

Panel discussion of audience questions and comments. **Frank Uhlig** (Auburn University, USA), Edward Hubbard (INSERM, France), Anne Greenbaum (University of Washington, USA) IC/MT4570/174

We shall discuss topics from mathematical education, human math abilities, and the role of math teachers, students and curricula with the audience.

17: Education Culture and History, Contributed Talks

17: Education Culture and History, Posters

IC/PP2425/017: **Mathematical notation and the use of functions.**

Presenter: Henning Thielemann (Universität Halle-Wittenberg, Germany)

In contrast to natural languages, mathematical notation is accepted as being exceptionally precise. It shall make mathematical statements unambiguous, it shall allow formal manipulation, it is model for programming languages, computer algebra systems and machine provers. However, what is "mathematical notation" today and is it indeed as precise as expected?

On the poster we discuss some examples of notation which require caution. How are they adapted in computer algebra systems? Can we replace them by something less problematic? What can we learn from functional programming?

IC/PP4393/172: **Teaching mathematics to engineers with *Mathematica*.**

Presenter: Conchita Marin (Universidad de Extremadura, Spain)

Over last years, increasing using of informatics tools on education is absolutely generalized, in particular, interesting mathematics software with large-scale applications has been developed. It has been proved, they are a very good help on learning not only because rapid calculations are possible, but because they let students to reach concepts in a clearer way. Moreover, in the formation of a future engineer, it is important to get him a correct and fluent interpretation of numerical results. On other hand, they should be able to design their own programs to solve problems. In this sense, using any kind of mathematical software integrating numeric and symbolic computation will be a no discussible help. In this work, academic results of students learning with Mathematica are analyzed. This software was used to teach "Numeric Calculus", an optional subject which students can choose from his second year on the university, so that, all of them have already attended to a course on Mathematics Fundaments of Engineer at his first year. The number of students was never more than twenty five in order to get a good evaluation of the efficiency of the methodology employed. The results correspond to the last five years in an Engineer School.
